The **name** content attribute gives the name of the form control, as used in [form submission<sup>p628</sup>](#) and in the [form<sup>p514</sup>](#) element's [elements<sup>p516</sup>](#) object. If the attribute is specified, its value must not be the empty string or `isindex`.

#### Note

*A number of user agents historically implemented special support for first-in-form text controls with the name `isindex`, and this specification previously defined related user agent requirements for it. However, some user agents subsequently dropped that special support, and the related requirements were removed from this specification. So, to avoid problematic reinterpretations in legacy user agents, the name `isindex` is no longer allowed.*

Other than `isindex`, any non-empty value for [name<sup>p515</sup>](#) is allowed. An [ASCII case-insensitive](#) match for the name `_charset_` is special: if used as the name of a [Hidden<sup>p527</sup>](#) control with no [value<sup>p525</sup>](#) attribute, then during submission the [value<sup>p525</sup>](#) attribute is automatically given a value consisting of the submission character encoding.

The **name** IDL attribute must [reflect](#)<sup>p104</sup> the **name**<sup>p599</sup> content attribute.

#### Note

DOM clobbering is a common cause of security issues. Avoid using the names of built-in form properties with the **name**<sup>p599</sup> content attribute.

In this example, the **input**<sup>p520</sup> element overrides the built-in **method**<sup>p602</sup> property:

```
let form = document.createElement("form");
let input = document.createElement("input");
form.appendChild(input);

form.method;           // => "get"
input.name = "method"; // DOM clobbering occurs here
form.method === input; // => true
```

Since the input name takes precedence over built-in form properties, the JavaScript reference `form.method` will point to the **input**<sup>p520</sup> element named "method" instead of the built-in **method**<sup>p602</sup> property.

#### 4.10.18.2 Submitting element directionality: the **dirname**<sup>p600</sup> attribute <sup>p600</sup><sub>0</sub>

The **dirname** attribute on a form control element enables the submission of [the directionality](#)<sup>p160</sup> of the element, and gives the name of the control that contains this value during [form submission](#)<sup>p628</sup>. If such an attribute is specified, its value must not be the empty string.

#### Example

In this example, a form contains a text control and a submission button:

```
<form action="addcomment.cgi" method=post>
  <p><label>Comment: <input type=text name="comment" dirname="comment.dir" required></label></p>
  <p><button name="mode" type=submit value="add">Post Comment</button></p>
</form>
```

When the user submits the form, the user agent includes three fields, one called "comment", one called "comment.dir", and one called "mode"; so if the user types "Hello", the submission body might be something like:

```
comment=Hello&comment.dir=ltr&mode=add
```

If the user manually switches to a right-to-left writing direction and enters "مرحبا", the submission body might be something like:

```
comment=%D9%85%D8%B1%D8%AD%D8%A8%D8%A7&comment.dir=rtl&mode=add
```

#### 4.10.18.3 Limiting user input length: the **maxlength**<sup>p600</sup> attribute <sup>p600</sup><sub>0</sub>

A **form control** **maxlength** attribute, controlled by the [dirty value flag](#)<sup>p597</sup>, declares a limit on the number of characters a user can input. The number of characters is measured using [length](#) and, in the case of [textarea](#)<sup>p579</sup> elements, with all newlines normalized to a single character (as opposed to CRLF pairs).

If an element has its [form control maxlength attribute](#)<sup>p600</sup> specified, the attribute's value must be a [valid non-negative integer](#)<sup>p77</sup>. If the attribute is specified and applying the [rules for parsing non-negative integers](#)<sup>p77</sup> to its value results in a number, then that number is the element's **maximum allowed value length**. If the attribute is omitted or parsing its value results in an error, then there is no [maximum allowed value length](#)<sup>p600</sup>.

**Constraint validation:** If an element has a [maximum allowed value length](#)<sup>p600</sup>, its [dirty value flag](#)<sup>p597</sup> is true, its [value](#)<sup>p597</sup> was last changed by a user edit (as opposed to a change made by a script), and the [length](#) of the element's [API value](#)<sup>p597</sup> is greater than the element's [maximum allowed value length](#)<sup>p600</sup>, then the element is [suffering from being too long](#)<sup>p623</sup>.

User agents may prevent the user from causing the element's [API value](#)<sup>p597</sup> to be set to a value whose [length](#) is greater than the

element's [maximum allowed value length](#)<sup>p600</sup>.

#### Note

In the case of [textarea](#)<sup>p579</sup> elements, the [API value](#)<sup>p597</sup> and [value](#)<sup>p597</sup> differ. In particular, [newline normalization](#) is applied before the [maximum allowed value length](#)<sup>p600</sup> is checked (whereas the [textarea wrapping transformation](#)<sup>p582</sup> is not applied).

#### 4.10.18.4 Setting minimum input length requirements: the [minlength](#)<sup>p601</sup> attribute §<sup>p60</sup><sub>1</sub>

A form control **minlength attribute**, controlled by the [dirty value flag](#)<sup>p597</sup>, declares a lower bound on the number of characters a user can input. The "number of characters" is measured using [length](#) and, in the case of [textarea](#)<sup>p579</sup> elements, with all newlines normalized to a single character (as opposed to CRLF pairs).

#### Note

The [minlength](#)<sup>p601</sup> attribute does not imply the [required attribute](#). If the form control has no [required attribute](#), then the value can still be omitted; the [minlength](#)<sup>p601</sup> attribute only kicks in once the user has entered a value at all. If the empty string is not allowed, then the [required attribute](#) also needs to be set.

If an element has its [form control minlength attribute](#)<sup>p601</sup> specified, the attribute's value must be a [valid non-negative integer](#)<sup>p77</sup>. If the attribute is specified and applying the [rules for parsing non-negative integers](#)<sup>p77</sup> to its value results in a number, then that number is the element's **minimum allowed value length**. If the attribute is omitted or parsing its value results in an error, then there is no [minimum allowed value length](#)<sup>p601</sup>.

If an element has both a [maximum allowed value length](#)<sup>p600</sup> and a [minimum allowed value length](#)<sup>p601</sup>, the [minimum allowed value length](#)<sup>p601</sup> must be smaller than or equal to the [maximum allowed value length](#)<sup>p600</sup>.

**Constraint validation:** If an element has a [minimum allowed value length](#)<sup>p601</sup>, its [dirty value flag](#)<sup>p597</sup> is true, its [value](#)<sup>p597</sup> was last changed by a user edit (as opposed to a change made by a script), its [value](#)<sup>p597</sup> is not the empty string, and the [length](#) of the element's [API value](#)<sup>p597</sup> is less than the element's [minimum allowed value length](#)<sup>p601</sup>, then the element is [suffering from being too short](#)<sup>p623</sup>.

#### Example

In this example, there are four text controls. The first is required, and has to be at least 5 characters long. The other three are optional, but if the user fills one in, the user has to enter at least 10 characters.

```
<form action="/events/menu.cgi" method="post">
  <p><label>Name of Event: <input required minlength=5 maxlength=50 name=event></label></p>
  <p><label>Describe what you would like for breakfast, if anything:
    <textarea name="breakfast" minlength="10"></textarea></label></p>
  <p><label>Describe what you would like for lunch, if anything:
    <textarea name="lunch" minlength="10"></textarea></label></p>
  <p><label>Describe what you would like for dinner, if anything:
    <textarea name="dinner" minlength="10"></textarea></label></p>
  <p><input type=submit value="Submit Request"></p>
</form>
```

#### 4.10.18.5 Enabling and disabling form controls: the [disabled](#)<sup>p601</sup> attribute §<sup>p60</sup><sub>1</sub>

The **disabled** content attribute is a [boolean attribute](#)<sup>p75</sup>.

#### Note

The [disabled](#)<sup>p578</sup> attribute for [option](#)<sup>p577</sup> elements and the [disabled](#)<sup>p576</sup> attribute for [optgroup](#)<sup>p576</sup> elements are defined separately.

A form control is **disabled** if any of the following are true:

- the element is a [button](#)<sup>p566</sup>, [input](#)<sup>p520</sup>, [select](#)<sup>p568</sup>, [textarea](#)<sup>p579</sup>, or [form-associated custom element](#)<sup>p760</sup>, and the [disabled](#)<sup>p601</sup> attribute is specified on this element (regardless of its value); or

- the element is a descendant of a [fieldset<sup>p594</sup>](#) element whose [disabled<sup>p594</sup>](#) attribute is specified, and is *not* a descendant of that [fieldset<sup>p594</sup>](#) element's first [legend<sup>p596</sup>](#) element child, if any.

A form control that is [disabled<sup>p601</sup>](#) must prevent any [click](#) events that are [queued<sup>p1125</sup>](#) on the [user interaction task source<sup>p1134</sup>](#) from being dispatched on the element.

**Constraint validation:** If an element is [disabled<sup>p601</sup>](#), it is [barred from constraint validation<sup>p622</sup>](#).

The [disabled](#) IDL attribute must [reflect<sup>p104</sup>](#) the [disabled<sup>p601</sup>](#) content attribute.

#### 4.10.18.6 Form submission attributes <sup>p60</sup><sub>2</sub>

**Attributes for form submission** can be specified both on [form<sup>p514</sup>](#) elements and on [submit buttons<sup>p514</sup>](#) (elements that represent buttons that submit forms, e.g. an [input<sup>p520</sup>](#) element whose [type<sup>p523</sup>](#) attribute is in the [Submit Button<sup>p546</sup>](#) state).

The [attributes for form submission<sup>p602</sup>](#) that may be specified on [form<sup>p514</sup>](#) elements are [action<sup>p602</sup>](#), [enctype<sup>p603</sup>](#), [method<sup>p602</sup>](#), [novalidate<sup>p603</sup>](#), and [target<sup>p603</sup>](#).

The corresponding [attributes for form submission<sup>p602</sup>](#) that may be specified on [submit buttons<sup>p514</sup>](#) are [formation<sup>p602</sup>](#), [formenctype<sup>p603</sup>](#), [formmethod<sup>p602</sup>](#), [formnovalidate<sup>p603</sup>](#), and [formtarget<sup>p603</sup>](#). When omitted, they default to the values given on the corresponding attributes on the [form<sup>p514</sup>](#) element.

The [action](#) and [formation](#) content attributes, if specified, must have a value that is a [valid non-empty URL potentially surrounded by spaces<sup>p96</sup>](#).

The [action](#) of an element is the value of the element's [formation<sup>p602</sup>](#) attribute, if the element is a [submit button<sup>p514</sup>](#) and has such an attribute, or the value of its [form owner<sup>p598</sup>](#)'s [action<sup>p602</sup>](#) attribute, if *it* has one, or else the empty string.

The [method](#) and [formmethod](#) content attributes are [enumerated attributes<sup>p76</sup>](#) with the following keywords and states:

Keyword	State	Brief description
<a href="#">get</a>	<a href="#">GET</a>	Indicates the <a href="#">form<sup>p514</sup></a> will use the HTTP GET method.
<a href="#">post</a>	<a href="#">POST</a>	Indicates the <a href="#">form<sup>p514</sup></a> will use the HTTP POST method.
<a href="#">dialog</a>	<a href="#">Dialog</a>	Indicates the <a href="#">form<sup>p514</sup></a> is intended to close the <a href="#">dialog<sup>p646</sup></a> box in which the form finds itself, if any, and otherwise not submit.

The [method<sup>p602</sup>](#) attribute's [missing value default<sup>p76</sup>](#) and [invalid value default<sup>p76</sup>](#) are both the [GET<sup>p602</sup>](#) state.

The [formmethod<sup>p602</sup>](#) attribute has no [missing value default<sup>p76</sup>](#), and its [invalid value default<sup>p76</sup>](#) is the [GET<sup>p602</sup>](#) state.

The [method](#) of an element is one of those states. If the element is a [submit button<sup>p514</sup>](#) and has a [formmethod<sup>p602</sup>](#) attribute, then the element's [method<sup>p602</sup>](#) is that attribute's state; otherwise, it is the [form owner<sup>p598</sup>](#)'s [method<sup>p602</sup>](#) attribute's state.

#### Example

Here the [method<sup>p602</sup>](#) attribute is used to explicitly specify the default value, "[get<sup>p602</sup>](#)", so that the search query is submitted in the URL:

```
<form method="get" action="/search.cgi">
  <p><label>Search terms: <input type=search name=q></label></p>
  <p><input type=submit></p>
</form>
```

#### Example

On the other hand, here the [method<sup>p602</sup>](#) attribute is used to specify the value "[post<sup>p602</sup>](#)", so that the user's message is submitted in the HTTP request's body:

```
<form method="post" action="/post-message.cgi">
```

```
<p><label>Message: <input type=text name=m></label></p>
<p><input type=submit value="Submit message"></p>
</form>
```

### Example

In this example, a [form](#)<sup>p514</sup> is used with a [dialog](#)<sup>p646</sup>. The [method](#)<sup>p602</sup> attribute's "[dialog](#)<sup>p602</sup>" keyword is used to have the dialog automatically close when the form is submitted.

```
<dialog id="ship">
  <form method=dialog>
    <p>A ship has arrived in the harbour.</p>
    <button type=submit value="board">Board the ship</button>
    <button type=submit value="call">Call to the captain</button>
  </form>
</dialog>
<script>
  var ship = document.getElementById('ship');
  ship.showModal();
  ship.onclose = function (event) {
    if (ship.returnValue == 'board') {
      // ...
    } else {
      // ...
    }
  };
</script>
```

The [enctype](#) and [formenctype](#) content attributes are [enumerated attributes](#)<sup>p76</sup> with the following keywords and states:

- The "[application/x-www-form-urlencoded](#)" keyword and corresponding state.
- The "[multipart/form-data](#)" keyword and corresponding state.
- The "[text/plain](#)" keyword and corresponding state.

The attribute's [missing value default](#)<sup>p76</sup> and [invalid value default](#)<sup>p76</sup> are both the [application/x-www-form-urlencoded](#)<sup>p603</sup> state.

The [formenctype](#)<sup>p603</sup> attribute has no [missing value default](#)<sup>p76</sup>, and its [invalid value default](#)<sup>p76</sup> is the [application/x-www-form-urlencoded](#)<sup>p603</sup> state.

The **enctype** of an element is one of those three states. If the element is a [submit button](#)<sup>p514</sup> and has a [formenctype](#)<sup>p603</sup> attribute, then the element's [enctype](#)<sup>p603</sup> is that attribute's state; otherwise, it is the [form owner](#)<sup>p598</sup>'s [enctype](#)<sup>p603</sup> attribute's state.

The [target](#) and [formtarget](#) content attributes, if specified, must have values that are [valid navigable target names or keywords](#)<sup>p996</sup>.

The [novalidate](#) and [formnovalidate](#) content attributes are [boolean attributes](#)<sup>p75</sup>. If present, they indicate that the form is not to be validated during submission.

The **no-validate state** of an element is true if the element is a [submit button](#)<sup>p514</sup> and the element's [formnovalidate](#)<sup>p603</sup> attribute is present, or if the element's [form owner](#)<sup>p598</sup>'s [novalidate](#)<sup>p603</sup> attribute is present, and false otherwise.

### Example

This attribute is useful to include "save" buttons on forms that have validation constraints, to allow users to save their progress even though they haven't fully entered the data in the form. The following example shows a simple form that has two required fields. There are three buttons: one to submit the form, which requires both fields to be filled in; one to save the form so that the

user can come back and fill it in later; and one to cancel the form altogether.

```
<form action="editor.cgi" method="post">
  <p><label>Name: <input required name=fn></label></p>
  <p><label>Essay: <textarea required name=essay></textarea></label></p>
  <p><input type=submit name=submit value="Submit essay"></p>
  <p><input type=submit formnovalidate name=save value="Save essay"></p>
  <p><input type=submit formnovalidate name=cancel value="Cancel"></p>
</form>
```

The **action** IDL attribute must [reflect](#)<sup>p104</sup> the content attribute of the same name, except that on getting, when the content attribute is missing or its value is the empty string, the element's [node document](#)'s [URL](#) must be returned instead. The **target** IDL attribute must [reflect](#)<sup>p104</sup> the content attribute of the same name. The **method** and **enctype** IDL attributes must [reflect](#)<sup>p104</sup> the respective content attributes of the same name, [limited to only known values](#)<sup>p105</sup>. The **encoding** IDL attribute must [reflect](#)<sup>p104</sup> the [enctype](#)<sup>p603</sup> content attribute, [limited to only known values](#)<sup>p105</sup>. The **noValidate** IDL attribute must [reflect](#)<sup>p104</sup> the [novalidate](#)<sup>p603</sup> content attribute. The **formAction** IDL attribute must [reflect](#)<sup>p104</sup> the [formaction](#)<sup>p602</sup> content attribute, except that on getting, when the content attribute is missing or its value is the empty string, the element's [node document](#)'s [URL](#) must be returned instead. The **formEnctype** IDL attribute must [reflect](#)<sup>p104</sup> the [formenctype](#)<sup>p603</sup> content attribute, [limited to only known values](#)<sup>p105</sup>. The **formMethod** IDL attribute must [reflect](#)<sup>p104</sup> the [formmethod](#)<sup>p602</sup> content attribute, [limited to only known values](#)<sup>p105</sup>. The **formNoValidate** IDL attribute must [reflect](#)<sup>p104</sup> the [formnovalidate](#)<sup>p603</sup> content attribute. The **formTarget** IDL attribute must [reflect](#)<sup>p104</sup> the [formtarget](#)<sup>p603</sup> content attribute.

#### 4.10.18.7 Autofill <sup>§ p60</sup><sub>4</sub>

##### 4.10.18.7.1 Autofilling form controls: the [autocomplete](#)<sup>p604</sup> attribute <sup>§ p60</sup><sub>4</sub>

User agents sometimes have features for helping users fill forms in, for example prefilling the user's address based on earlier user [input](#). The **autocomplete** content attribute can be used to hint to the user agent how to, or indeed whether to, provide such a feature.

There are two ways this attribute is used. When wearing the **autofill expectation mantle**, the [autocomplete](#)<sup>p604</sup> attribute describes what input is expected from users. When wearing the **autofill anchor mantle**, the [autocomplete](#)<sup>p604</sup> attribute describes the meaning of the given value.

On an [input](#)<sup>p520</sup> element whose [type](#)<sup>p523</sup> attribute is in the [Hidden](#)<sup>p527</sup> state, the [autocomplete](#)<sup>p604</sup> attribute wears the [autofill anchor mantle](#)<sup>p604</sup>. In all other cases, it wears the [autofill expectation mantle](#)<sup>p604</sup>.

When wearing the [autofill expectation mantle](#)<sup>p604</sup>, the [autocomplete](#)<sup>p604</sup> attribute, if specified, must have a value that is an ordered [set of space-separated tokens](#)<sup>p94</sup> consisting of either a single token that is an [ASCII case-insensitive](#) match for the string "[off](#)<sup>p606</sup>", or a single token that is an [ASCII case-insensitive](#) match for the string "[on](#)<sup>p606</sup>", or [autofill detail tokens](#)<sup>p604</sup>.

When wearing the [autofill anchor mantle](#)<sup>p604</sup>, the [autocomplete](#)<sup>p604</sup> attribute, if specified, must have a value that is an ordered [set of space-separated tokens](#)<sup>p94</sup> consisting of just [autofill detail tokens](#)<sup>p604</sup> (i.e. the "[on](#)<sup>p606</sup>" and "[off](#)<sup>p606</sup>" keywords are not allowed).

**Autofill detail tokens** are the following, in the order given below:

1. Optionally, a token whose first eight characters are an [ASCII case-insensitive](#) match for the string "**section-**", meaning that the field belongs to the named group.

#### Example

For example, if there are two shipping addresses in the form, then they could be marked up as:

```
<fieldset>
  <legend>Ship the blue gift to...</legend>
  <p> <label> Address:      <textarea name=ba autocomplete="section-blue shipping street-
address"></textarea> </label>
  <p> <label> City:        <input name=bc autocomplete="section-blue shipping address-
level2"> </label>
  <p> <label> Postal Code: <input name=bp autocomplete="section-blue shipping postal-code">
</label>
```

```

</fieldset>
<fieldset>
  <legend>Ship the red gift to...</legend>
  <p> <label> Address:      <textarea name=ra autocomplete="section-red shipping street-
address"></textarea> </label>
  <p> <label> City:        <input name=rc autocomplete="section-red shipping address-
level2"> </label>
  <p> <label> Postal Code: <input name=rp autocomplete="section-red shipping postal-code">
</label>
</fieldset>

```

2. Optionally, a token that is an [ASCII case-insensitive](#) match for one of the following strings:

- **"shipping"**, meaning the field is part of the shipping address or contact information
- **"billing"**, meaning the field is part of the billing address or contact information

3. Either of the following two options:

- A token that is an [ASCII case-insensitive](#) match for one of the following [autofill field](#)<sup>p606</sup> names, excluding those that are [inappropriate for the control](#)<sup>p607</sup>:

- ["name"](#)<sup>p607</sup>
- ["honorific-prefix"](#)<sup>p607</sup>
- ["given-name"](#)<sup>p607</sup>
- ["additional-name"](#)<sup>p607</sup>
- ["family-name"](#)<sup>p607</sup>
- ["honorific-suffix"](#)<sup>p607</sup>
- ["nickname"](#)<sup>p607</sup>
- ["username"](#)<sup>p607</sup>
- ["new-password"](#)<sup>p607</sup>
- ["current-password"](#)<sup>p607</sup>
- ["one-time-code"](#)<sup>p607</sup>
- ["organization-title"](#)<sup>p607</sup>
- ["organization"](#)<sup>p607</sup>
- ["street-address"](#)<sup>p607</sup>
- ["address-line1"](#)<sup>p607</sup>
- ["address-line2"](#)<sup>p607</sup>
- ["address-line3"](#)<sup>p607</sup>
- ["address-line4"](#)<sup>p607</sup>
- ["address-level3"](#)<sup>p607</sup>
- ["address-level2"](#)<sup>p607</sup>
- ["address-level1"](#)<sup>p607</sup>
- ["country"](#)<sup>p607</sup>
- ["country-name"](#)<sup>p608</sup>
- ["postal-code"](#)<sup>p608</sup>
- ["cc-name"](#)<sup>p608</sup>
- ["cc-given-name"](#)<sup>p608</sup>
- ["cc-additional-name"](#)<sup>p608</sup>
- ["cc-family-name"](#)<sup>p608</sup>
- ["cc-number"](#)<sup>p608</sup>
- ["cc-exp"](#)<sup>p608</sup>
- ["cc-exp-month"](#)<sup>p608</sup>
- ["cc-exp-year"](#)<sup>p608</sup>
- ["cc-csc"](#)<sup>p608</sup>
- ["cc-type"](#)<sup>p608</sup>
- ["transaction-currency"](#)<sup>p608</sup>
- ["transaction-amount"](#)<sup>p608</sup>
- ["language"](#)<sup>p608</sup>
- ["bday"](#)<sup>p608</sup>
- ["bday-day"](#)<sup>p608</sup>
- ["bday-month"](#)<sup>p608</sup>
- ["bday-year"](#)<sup>p608</sup>
- ["sex"](#)<sup>p608</sup>
- ["url"](#)<sup>p608</sup>
- ["photo"](#)<sup>p608</sup>

(See the table below for descriptions of these values.)

- The following, in the given order:

1. Optionally, a token that is an [ASCII case-insensitive](#) match for one of the following strings:

- "home", meaning the field is for contacting someone at their residence
  - "work", meaning the field is for contacting someone at their workplace
  - "mobile", meaning the field is for contacting someone regardless of location
  - "fax", meaning the field describes a fax machine's contact details
  - "pager", meaning the field describes a pager's or beeper's contact details
2. A token that is an [ASCII case-insensitive](#) match for one of the following [autofill field](#)<sup>p606</sup> names, excluding those that are [inappropriate for the control](#)<sup>p607</sup>:

- "tel"<sup>p608</sup>
- "tel-country-code"<sup>p608</sup>
- "tel-national"<sup>p608</sup>
- "tel-area-code"<sup>p608</sup>
- "tel-local"<sup>p608</sup>
- "tel-local-prefix"<sup>p608</sup>
- "tel-local-suffix"<sup>p609</sup>
- "tel-extension"<sup>p609</sup>
- "email"<sup>p609</sup>
- "impp"<sup>p609</sup>

(See the table below for descriptions of these values.)

4. Optionally, a token that is an [ASCII case-insensitive](#) match for the string "webauthn", meaning the user agent should show [public key credentials](#) available via [conditional](#) mediation when the user interacts with the form control. [webauthn](#)<sup>p606</sup> is only valid for [input](#)<sup>p520</sup> and [textarea](#)<sup>p579</sup> elements.

As noted earlier, the meaning of the attribute and its keywords depends on the mantle that the attribute is wearing.

#### ↪ When wearing the [autofill expectation mantle](#)<sup>p604</sup>...

The "off" keyword indicates either that the control's input data is particularly sensitive (for example the activation code for a nuclear weapon); or that it is a value that will never be reused (for example a one-time-key for a bank login) and the user will therefore have to explicitly enter the data each time, instead of being able to rely on the UA to prefill the value for them; or that the document provides its own autocomplete mechanism and does not want the user agent to provide autocompletion values.

The "on" keyword indicates that the user agent is allowed to provide the user with autocompletion values, but does not provide any further information about what kind of data the user might be expected to enter. User agents would have to use heuristics to decide what autocompletion values to suggest.

The [autofill field](#)<sup>p606</sup> listed above indicate that the user agent is allowed to provide the user with autocompletion values, and specifies what kind of value is expected. The meaning of each such keyword is described in the table below.

If the [autocomplete](#)<sup>p604</sup> attribute is omitted, the default value corresponding to the state of the element's [form owner](#)<sup>p598</sup>'s [autocomplete](#)<sup>p515</sup> attribute is used instead (either "on"<sup>p606</sup> or "off"<sup>p606</sup>). If there is no [form owner](#)<sup>p598</sup>, then the value "on"<sup>p606</sup> is used.

#### ↪ When wearing the [autofill anchor mantle](#)<sup>p604</sup>...

The [autofill field](#)<sup>p606</sup> listed above indicate that the value of the particular kind of value specified is that value provided for this element. The meaning of each such keyword is described in the table below.

#### Example

In this example the page has explicitly specified the currency and amount of the transaction. The form requests a credit card and other billing details. The user agent could use this information to suggest a credit card that it knows has sufficient balance and that supports the relevant currency.

```
<form method=post action="step2.cgi">
  <input type=hidden autocomplete=transaction-currency value="CHF">
  <input type=hidden autocomplete=transaction-amount value="15.00">
  <p><label>Credit card number: <input type=text inputmode=numeric autocomplete=cc-
number></label>
  <p><label>Expiry Date: <input type=month autocomplete=cc-exp></label>
  <p><input type=submit value="Continue...">
</form>
```

The **autofill field** keywords relate to each other as described in the table below. Each field name listed on a row of this table corresponds to the meaning given in the cell for that row in the column labeled "Meaning". Some fields correspond to subparts of other fields; for example, a credit card expiry date can be expressed as one field giving both the month and year of expiry ("cc-exp"<sup>p608</sup>), or

as two fields, one giving the month ("[cc-exp-month](#)<sup>p688</sup>") and one the year ("[cc-exp-year](#)<sup>p688</sup>"). In such cases, the names of the broader fields cover multiple rows, in which the narrower fields are defined.

#### Note

*Generally, authors are encouraged to use the broader fields rather than the narrower fields, as the narrower fields tend to expose Western biases. For example, while it is common in some Western cultures to have a given name and a family name, in that order (and thus often referred to as a first name and a surname), many cultures put the family name first and the given name second, and many others simply have one name (a mononym). Having a single field is therefore more flexible.*

Some fields are only appropriate for certain form controls. An [autofill field](#)<sup>p606</sup> name is **inappropriate for a control** if the control does not belong to the group listed for that [autofill field](#)<sup>p606</sup> in the fifth column of the first row describing that [autofill field](#)<sup>p606</sup> in the table below. What controls fall into each group is described below the table.

Field name	Meaning	Canonical Format	Canonical Format Example	Control group
"name"	Full name	Free-form text, no newlines	Sir Timothy John Berners-Lee, OM, KBE, FRS, FEng, FRSA	<a href="#">Text</a> <sup>p609</sup>
" <a href="#">honorific-prefix</a> "	Prefix or title (e.g. "Mr.", "Ms.", "Dr.", "Mlle")	Free-form text, no newlines	Sir	<a href="#">Text</a> <sup>p609</sup>
" <a href="#">given-name</a> "	Given name (in some Western cultures, also known as the <i>first name</i> )	Free-form text, no newlines	Timothy	<a href="#">Text</a> <sup>p609</sup>
" <a href="#">additional-name</a> "	Additional names (in some Western cultures, also known as <i>middle names</i> , forenames other than the first name)	Free-form text, no newlines	John	<a href="#">Text</a> <sup>p609</sup>
" <a href="#">family-name</a> "	Family name (in some Western cultures, also known as the <i>last name</i> or <i>surname</i> )	Free-form text, no newlines	Berners-Lee	<a href="#">Text</a> <sup>p609</sup>
" <a href="#">honorific-suffix</a> "	Suffix (e.g. "Jr.", "B.Sc.", "MBASW", "II")	Free-form text, no newlines	OM, KBE, FRS, FEng, FRSA	<a href="#">Text</a> <sup>p609</sup>
" <a href="#">nickname</a> "	Nickname, screen name, handle: a typically short name used instead of the full name	Free-form text, no newlines	Tim	<a href="#">Text</a> <sup>p609</sup>
" <a href="#">organization-title</a> "	Job title (e.g. "Software Engineer", "Senior Vice President", "Deputy Managing Director")	Free-form text, no newlines	Professor	<a href="#">Text</a> <sup>p609</sup>
" <a href="#">username</a> "	A username	Free-form text, no newlines	timbl	<a href="#">Username</a> <sup>p609</sup>
" <a href="#">new-password</a> "	A new password (e.g. when creating an account or changing a password)	Free-form text, no newlines	GUMFXbadyrS3	<a href="#">Password</a> <sup>p609</sup>
" <a href="#">current-password</a> "	The current password for the account identified by the <a href="#">username</a> <sup>p687</sup> field (e.g. when logging in)	Free-form text, no newlines	qwerty	<a href="#">Password</a> <sup>p609</sup>
" <a href="#">one-time-code</a> "	One-time code used for verifying user identity	Free-form text, no newlines	123456	<a href="#">Password</a> <sup>p609</sup>
" <a href="#">organization</a> "	Company name corresponding to the person, address, or contact information in the other fields associated with this field	Free-form text, no newlines	World Wide Web Consortium	<a href="#">Text</a> <sup>p609</sup>
" <a href="#">street-address</a> "	Street address (multiple lines, newlines preserved)	Free-form text	32 Vassar Street MIT Room 32-G524	<a href="#">Multiline</a> <sup>p609</sup>
" <a href="#">address-line1</a> "	Street address (one line per field)	Free-form text, no newlines	32 Vassar Street	<a href="#">Text</a> <sup>p609</sup>
" <a href="#">address-line2</a> "		Free-form text, no newlines	MIT Room 32-G524	<a href="#">Text</a> <sup>p609</sup>
" <a href="#">address-line3</a> "		Free-form text, no newlines		<a href="#">Text</a> <sup>p609</sup>
" <a href="#">address-level4</a> "	The most fine-grained <a href="#">administrative level</a> <sup>p610</sup> , in addresses with four administrative levels	Free-form text, no newlines		<a href="#">Text</a> <sup>p609</sup>
" <a href="#">address-level3</a> "	The <a href="#">third administrative level</a> <sup>p610</sup> , in addresses with three or more administrative levels	Free-form text, no newlines		<a href="#">Text</a> <sup>p609</sup>
" <a href="#">address-level2</a> "	The <a href="#">second administrative level</a> <sup>p610</sup> , in addresses with two or more administrative levels; in the countries with two administrative levels, this would typically be the city, town, village, or other locality within which the relevant street address is found	Free-form text, no newlines	Cambridge	<a href="#">Text</a> <sup>p609</sup>
" <a href="#">address-level1</a> "	The broadest <a href="#">administrative level</a> <sup>p610</sup> in the address, i.e. the province within which the locality is found; for example, in the US, this would be the state; in Switzerland it would be the canton; in the UK, the post town	Free-form text, no newlines	MA	<a href="#">Text</a> <sup>p609</sup>
" <a href="#">country</a> "	Country code	Valid <a href="#">ISO 3166-1-alpha-2 country code</a>	US	<a href="#">Text</a> <sup>p609</sup>

Field name	Meaning	Canonical Format	Canonical Format Example	Control group
		<a href="#">[ISO3166]</a> <sup>p1479</sup>		
"country-name"	Country name	Free-form text, no newlines; <a href="#">derived from country in some cases</a> <sup>p615</sup>	US	<a href="#">Text</a> <sup>p609</sup>
"postal-code"	Postal code, post code, ZIP code, CEDEX code (if CEDEX, append "CEDEX", and the <i>arrondissement</i> , if relevant, to the <a href="#">address-level2</a> <sup>p607</sup> field)	Free-form text, no newlines	02139	<a href="#">Text</a> <sup>p609</sup>
"cc-name"	Full name as given on the payment instrument	Free-form text, no newlines	Tim Berners-Lee	<a href="#">Text</a> <sup>p609</sup>
"cc-given-name"	Given name as given on the payment instrument (in some Western cultures, also known as the <i>first name</i> )	Free-form text, no newlines	Tim	<a href="#">Text</a> <sup>p609</sup>
"cc-additional-name"	Additional names given on the payment instrument (in some Western cultures, also known as <i>middle names</i> , forenames other than the first name)	Free-form text, no newlines		<a href="#">Text</a> <sup>p609</sup>
"cc-family-name"	Family name given on the payment instrument (in some Western cultures, also known as the <i>last name</i> or <i>surname</i> )	Free-form text, no newlines	Berners-Lee	<a href="#">Text</a> <sup>p609</sup>
"cc-number"	Code identifying the payment instrument (e.g. the credit card number)	<a href="#">ASCII digits</a>	4114360123456785	<a href="#">Text</a> <sup>p609</sup>
"cc-exp"	Expiration date of the payment instrument	<a href="#">Valid month string</a> <sup>p82</sup>	2014-12	<a href="#">Month</a> <sup>p610</sup>
"cc-exp-month"	Month component of the expiration date of the payment instrument	<a href="#">Valid integer</a> <sup>p76</sup> in the range 1..12	12	<a href="#">Numeric</a> <sup>p609</sup>
"cc-exp-year"	Year component of the expiration date of the payment instrument	<a href="#">Valid integer</a> <sup>p76</sup> greater than zero	2014	<a href="#">Numeric</a> <sup>p609</sup>
"cc-csc"	Security code for the payment instrument (also known as the card security code (CSC), card validation code (CVC), card verification value (CVV), signature panel code (SPC), credit card ID (CCID), etc.)	<a href="#">ASCII digits</a>	419	<a href="#">Text</a> <sup>p609</sup>
"cc-type"	Type of payment instrument	Free-form text, no newlines	Visa	<a href="#">Text</a> <sup>p609</sup>
"transaction-currency"	The currency that the user would prefer the transaction to use	ISO 4217 currency code <a href="#">[ISO4217]</a> <sup>p1479</sup>	GBP	<a href="#">Text</a> <sup>p609</sup>
"transaction-amount"	The amount that the user would like for the transaction (e.g. when entering a bid or sale price)	<a href="#">Valid floating-point number</a> <sup>p77</sup>	401.00	<a href="#">Numeric</a> <sup>p609</sup>
"language"	Preferred language	Valid BCP 47 language tag <a href="#">[BCP47]</a> <sup>p1475</sup>	en	<a href="#">Text</a> <sup>p609</sup>
"bday"	Birthday	<a href="#">Valid date string</a> <sup>p83</sup>	1955-06-08	<a href="#">Date</a> <sup>p610</sup>
"bday-day"	Day component of birthday	<a href="#">Valid integer</a> <sup>p76</sup> in the range 1..31	8	<a href="#">Numeric</a> <sup>p609</sup>
"bday-month"	Month component of birthday	<a href="#">Valid integer</a> <sup>p76</sup> in the range 1..12	6	<a href="#">Numeric</a> <sup>p609</sup>
"bday-year"	Year component of birthday	<a href="#">Valid integer</a> <sup>p76</sup> greater than zero	1955	<a href="#">Numeric</a> <sup>p609</sup>
"sex"	Gender identity (e.g. Female, Fa'afafine)	Free-form text, no newlines	Male	<a href="#">Text</a> <sup>p609</sup>
"url"	Home page or other web page corresponding to the company, person, address, or contact information in the other fields associated with this field	<a href="#">Valid URL string</a>	<a href="https://www.w3.org/People/Berners-Lee/">https://www.w3.org/People/Berners-Lee/</a>	<a href="#">URL</a> <sup>p609</sup>
"photo"	Photograph, icon, or other image corresponding to the company, person, address, or contact information in the other fields associated with this field	<a href="#">Valid URL string</a>	<a href="https://www.w3.org/Press/Stock/Berners-Lee/2001-europaeum-eighth.jpg">https://www.w3.org/Press/Stock/Berners-Lee/2001-europaeum-eighth.jpg</a>	<a href="#">URL</a> <sup>p609</sup>
"tel"	Full telephone number, including country code	<a href="#">ASCII digits</a> and U+0020 SPACE characters, prefixed by a U+002B PLUS SIGN character (+)	+1 617 253 5702	<a href="#">Tel</a> <sup>p609</sup>
"tel-country-code"	Country code component of the telephone number	<a href="#">ASCII digits</a> prefixed by a U+002B PLUS SIGN character (+)	+1	<a href="#">Text</a> <sup>p609</sup>
"tel-national"	Telephone number without the county code component, with a country-internal prefix applied if applicable	<a href="#">ASCII digits</a> and U+0020 SPACE characters	617 253 5702	<a href="#">Text</a> <sup>p609</sup>
"tel-area-code"	Area code component of the telephone number, with a country-internal prefix applied if applicable	<a href="#">ASCII digits</a>	617	<a href="#">Text</a> <sup>p609</sup>
"tel-local"	Telephone number without the country code and area code components	<a href="#">ASCII digits</a>	2535702	<a href="#">Text</a> <sup>p609</sup>
"tel-"	First part of the component of the telephone number that follows the area	<a href="#">ASCII digits</a>	253	<a href="#">Text</a> <sup>p609</sup>

Field name	Meaning	Canonical Format	Canonical Format Example	Control group
"local-prefix"	code, when that component is split into two components			
"tel-local-suffix"	Second part of the component of the telephone number that follows the area code, when that component is split into two components	<a href="#">ASCII digits</a>	5702	<a href="#">Text</a> <sup>p609</sup>
"tel-extension"	Telephone number internal extension code	<a href="#">ASCII digits</a>	1000	<a href="#">Text</a> <sup>p609</sup>
"email"	Email address	<a href="#">Valid email address</a> <sup>p531</sup>	timbl@w3.org	<a href="#">Username</a> <sup>p609</sup>
"impp"	URL representing an instant messaging protocol endpoint (for example, "aim:goim?screenname=example" or "xmpp:fred@example.net")	<a href="#">Valid URL string</a>	irc://example.org/timbl,user	<a href="#">URL</a> <sup>p609</sup>

The groups correspond to controls as follows:

### Text

[input](#) <sup>p520</sup> elements with a [type](#) <sup>p523</sup> attribute in the [Hidden](#) <sup>p527</sup> state

[textarea](#)<sup>p579</sup> elements  
[select](#)<sup>p568</sup> elements

**Address levels:** The "[address-level1](#)<sup>p607</sup>" – "[address-level4](#)<sup>p607</sup>" fields are used to describe the locality of the street address. Different locales have different numbers of levels. For example, the US uses two levels (state and town), the UK uses one or two depending on the address (the post town, and in some cases the locality), and China can use three (province, city, district). The "[address-level1](#)<sup>p607</sup>" field represents the widest administrative division. Different locales order the fields in different ways; for example, in the US the town (level 2) precedes the state (level 1); while in Japan the prefecture (level 1) precedes the city (level 2) which precedes the district (level 3). Authors are encouraged to provide forms that are presented in a way that matches the country's conventions (hiding, showing, and rearranging fields accordingly as the user changes the country).

#### 4.10.18.7.2 Processing model <sup>§<sup>p61</sup></sup><sub>0</sub>

Each [input](#)<sup>p520</sup> element to which the [autocomplete](#)<sup>p604</sup> attribute [applies](#)<sup>p523</sup>, each [select](#)<sup>p568</sup> element, and each [textarea](#)<sup>p579</sup> element, has an **autofill hint set**, an **autofill scope**, an **autofill field name**, a **non-autofill credential type**, and an **IDL-exposed autofill value**.

The [autofill field name](#)<sup>p610</sup> specifies the specific kind of data expected in the field, e.g. "[street-address](#)<sup>p607</sup>" or "[cc-exp](#)<sup>p608</sup>".

The [autofill hint set](#)<sup>p610</sup> identifies what address or contact information type the user agent is to look at, e.g. "[shipping](#)<sup>p605</sup> [fax](#)<sup>p606</sup>" or "[billing](#)<sup>p605</sup>".

The [non-autofill credential type](#)<sup>p610</sup> identifies a type of [credential](#) that may be offered by the user agent when the user interacts with the field alongside other [autofill field](#)<sup>p606</sup> values. If this value is "webauthn" instead of null, selecting a credential of that type will resolve a pending [conditional](#) mediation [navigator.credentials.get\(\)](#) request, instead of autofilling the field.

#### Example

For example, a sign-in page could instruct the user agent to either autofill a saved password, or show a [public key credential](#) that will resolve a pending [navigator.credentials.get\(\)](#) request. A user can select either to sign-in.

```
<input name=password type=password autocomplete="current-password webauthn">
```

The [autofill scope](#)<sup>p610</sup> identifies the group of fields whose information concerns the same subject, and consists of the [autofill hint set](#)<sup>p610</sup> with, if applicable, the "section-\*" prefix, e.g. "billing", "section-parent shipping", or "section-child shipping home".

These values are defined as the result of running the following algorithm:

1. If the element has no [autocomplete](#)<sup>p604</sup> attribute, then jump to the step labeled *default*.
2. Let *tokens* be the result of [splitting the attribute's value on ASCII whitespace](#).
3. If *tokens* is empty, then jump to the step labeled *default*.
4. Let *index* be the index of the last token in *tokens*.
5. Let *field* be the *index*th token in *tokens*.

6. Set the *category*, *maximum tokens* pair to the result of [determining a field's category](#)<sup>p612</sup> given *field*.
7. If *category* is null, then jump to the step labeled *default*.
8. If the number of tokens in *tokens* is greater than *maximum tokens*, then jump to the step labeled *default*.
9. If *category* is Off or Automatic but the element's [autocomplete](#)<sup>p604</sup> attribute is wearing the [autofill anchor mantle](#)<sup>p604</sup>, then jump to the step labeled *default*.
10. If *category* is Off, let the element's [autofill field name](#)<sup>p610</sup> be the string "off", let its [autofill hint set](#)<sup>p610</sup> be empty, and let its [IDL-exposed autofill value](#)<sup>p610</sup> be the string "off". Then, return.
11. If *category* is Automatic, let the element's [autofill field name](#)<sup>p610</sup> be the string "on", let its [autofill hint set](#)<sup>p610</sup> be empty, and let its [IDL-exposed autofill value](#)<sup>p610</sup> be the string "on". Then, return.
12. Let *scope tokens* be an empty list.
13. Let *hint tokens* be an empty set.
14. Let *credential type* be null.
15. Let *IDL value* have the same value as *field*.
16. If *category* is Credential and the *indexth* token in *tokens* is an [ASCII case-insensitive](#) match for "[webauthn](#)"<sup>p606</sup>, then run the substeps that follow:
  1. Set *credential type* to "webauthn".
  2. If the *indexth* token in *tokens* is the first entry, then skip to the step labeled *done*.
  3. Decrement *index* by one.
  4. Set the *category*, *maximum tokens* pair to the result of [determining a field's category](#)<sup>p612</sup> given the *indexth* token in *tokens*.
  5. If *category* is not Normal and *category* is not Contact, then jump to the step labeled *default*.
  6. If *index* is greater than *maximum tokens* minus one (i.e. if the number of remaining tokens is greater than *maximum tokens*), then jump to the step labeled *default*.
  7. Set *IDL value* to the concatenation of the *indexth* token in *tokens*, a U+0020 SPACE character, and the previous value of *IDL value*.
17. If the *indexth* token in *tokens* is the first entry, then skip to the step labeled *done*.
18. Decrement *index* by one.
19. If *category* is Contact and the *indexth* token in *tokens* is an [ASCII case-insensitive](#) match for one of the strings in the following list, then run the substeps that follow:
  - "[home](#)"<sup>p606</sup>
  - "[work](#)"<sup>p606</sup>
  - "[mobile](#)"<sup>p606</sup>
  - "[fax](#)"<sup>p606</sup>
  - "[pager](#)"<sup>p606</sup>

The substeps are:

1. Let *contact* be the matching string from the list above.
  2. Insert *contact* at the start of *scope tokens*.
  3. Add *contact* to *hint tokens*.
  4. Let *IDL value* be the concatenation of *contact*, a U+0020 SPACE character, and the previous value of *IDL value*.
  5. If the *indexth* entry in *tokens* is the first entry, then skip to the step labeled *done*.
  6. Decrement *index* by one.
20. If the *indexth* token in *tokens* is an [ASCII case-insensitive](#) match for one of the strings in the following list, then run the substeps that follow:

- "shipping<sup>p605</sup>"
- "billing<sup>p605</sup>"

The substeps are:

1. Let *mode* be the matching string from the list above.
  2. Insert *mode* at the start of *scope tokens*.
  3. Add *mode* to *hint tokens*.
  4. Let *IDL value* be the concatenation of *mode*, a U+0020 SPACE character, and the previous value of *IDL value*.
  5. If the *indexth* entry in *tokens* is the first entry, then skip to the step labeled *done*.
  6. Decrement *index* by one.
21. If the *indexth* entry in *tokens* is not the first entry, then jump to the step labeled *default*.
  22. If the first eight characters of the *indexth* token in *tokens* are not an [ASCII case-insensitive](#) match for the string "section-<sup>p604</sup>", then jump to the step labeled *default*.
  23. Let *section* be the *indexth* token in *tokens*, [converted to ASCII lowercase](#).
  24. Insert *section* at the start of *scope tokens*.
  25. Let *IDL value* be the concatenation of *section*, a U+0020 SPACE character, and the previous value of *IDL value*.
  26. *Done*: Let the element's [autofill hint set](#)<sup>p610</sup> be *hint tokens*.
  27. Let the element's [non-autofill credential type](#)<sup>p610</sup> be *credential type*.
  28. Let the element's [autofill scope](#)<sup>p610</sup> be *scope tokens*.
  29. Let the element's [autofill field name](#)<sup>p610</sup> be *field*.
  30. Let the element's [IDL-exposed autofill value](#)<sup>p610</sup> be *IDL value*.
  31. Return.
  32. *Default*: Let the element's [IDL-exposed autofill value](#)<sup>p610</sup> be the empty string, and its [autofill hint set](#)<sup>p610</sup> and [autofill scope](#)<sup>p610</sup> be empty.
  33. If the element's [autocomplete](#)<sup>p604</sup> attribute is wearing the [autofill anchor mantle](#)<sup>p604</sup>, then let the element's [autofill field name](#)<sup>p610</sup> be the empty string and return.
  34. Let *form* be the element's [form owner](#)<sup>p598</sup>, if any, or null otherwise.
  35. If *form* is not null and *form*'s [autocomplete](#)<sup>p515</sup> attribute is in the [off](#)<sup>p515</sup> state, then let the element's [autofill field name](#)<sup>p610</sup> be "off<sup>p606</sup>".

Otherwise, let the element's [autofill field name](#)<sup>p610</sup> be "on<sup>p606</sup>".

To **determine a field's category**, given *field*:

1. If the *field* is not an [ASCII case-insensitive](#) match for one of the tokens given in the first column of the following table, return the pair (null, null).

Token	Maximum number of tokens	Category
"off <sup>p606</sup> "	1	Off
"on <sup>p606</sup> "	1	Automatic
"name <sup>p607</sup> "	3	Normal
"honorific-prefix <sup>p607</sup> "	3	Normal
"given-name <sup>p607</sup> "	3	Normal
"additional-name <sup>p607</sup> "	3	Normal

- Otherwise, let *maximum tokens* and *category* be the values of the cells in the second and third columns of that row respectively.
- Return the pair (*category*, *maximum tokens*).

For the purposes of autofill, a **control's data** depends on the kind of control:

An [input](#)<sup>p520</sup> element with its [type](#)<sup>p523</sup> attribute in the [Email](#)<sup>p530</sup> state and with the [multiple](#)<sup>p553</sup> attribute specified  
The element's [values](#)<sup>p597</sup>.

Any other [input](#)<sup>p520</sup> element

A [textarea](#)<sup>p579</sup> element

The element's [value](#)<sup>p597</sup>.

A [select](#)<sup>p568</sup> element with its [multiple](#)<sup>p569</sup> attribute specified

The [option](#)<sup>p577</sup> elements in the [select](#)<sup>p568</sup> element's [list of options](#)<sup>p569</sup> that have their [selectedness](#)<sup>p578</sup> set to true.

Any other [select](#)<sup>p568</sup> element

The [option](#)<sup>p577</sup> element in the [select](#)<sup>p568</sup> element's [list of options](#)<sup>p569</sup> that has its [selectedness](#)<sup>p578</sup> set to true.

How to process the [autofill hint set](#)<sup>p610</sup>, [autofill scope](#)<sup>p610</sup>, and [autofill field name](#)<sup>p610</sup> depends on the mantle that the [autocomplete](#)<sup>p604</sup> attribute is wearing.

↪ When wearing the [autofill expectation mantle](#)<sup>p604</sup>...

When an element's [autofill field name](#)<sup>p610</sup> is "[off](#)<sup>p606</sup>", the user agent should not remember the [control's data](#)<sup>p613</sup>, and should not offer past values to the user.

#### Note

*In addition, when an element's [autofill field name](#)<sup>p610</sup> is "[off](#)<sup>p606</sup>", [values are reset](#)<sup>p1051</sup> when [reactivating a document](#)<sup>p1051</sup>.*

#### Example

Banks frequently do not want UAs to prefill login information:

```
<p><label>Account: <input type="text" name="ac" autocomplete="off"></label></p>
<p><label>PIN: <input type="password" name="pin" autocomplete="off"></label></p>
```

When an element's [autofill field name](#)<sup>p610</sup> is *not* "[off](#)<sup>p606</sup>", the user agent may store the [control's data](#)<sup>p613</sup>, and may offer previously stored values to the user.

#### Example

For example, suppose a user visits a page with this control:

```
<select name="country">
  <option>Afghanistan
  <option>Albania
  <option>Algeria
  <option>Andorra
  <option>Angola
  <option>Antigua and Barbuda
  <option>Argentina
  <option>Armenia
  <!-- ... -->
  <option>Yemen
  <option>Zambia
  <option>Zimbabwe
</select>
```

This might render as follows:

Suppose that on the first visit to this page, the user selects "Zambia". On the second visit, the user agent could duplicate the entry for Zambia at the top of the list, so that the interface instead looks like this:

When the [autofill field name](#)<sup>p610</sup> is "[on](#)<sup>p606</sup>", the user agent should attempt to use heuristics to determine the most appropriate values to offer the user, e.g. based on the element's [name](#)<sup>p599</sup> value, the position of the element in its [tree](#), what other fields exist in the form, and so forth.

When the [autofill field name](#)<sup>p610</sup> is one of the names of the [autofill fields](#)<sup>p606</sup> described above, the user agent should provide suggestions that match the meaning of the field name as given in the table earlier in this section. The [autofill hint set](#)<sup>p610</sup> should be used to select amongst multiple possible suggestions.

#### Example

For example, if a user once entered one address into fields that used the "[shipping](#)<sup>p605</sup>" keyword, and another address into fields that used the "[billing](#)<sup>p605</sup>" keyword, then in subsequent forms only the first address would be suggested for form controls whose [autofill hint set](#)<sup>p610</sup> contains the keyword "[shipping](#)<sup>p605</sup>". Both addresses might be suggested, however, for address-related form controls whose [autofill hint set](#)<sup>p610</sup> does not contain either keyword.

#### ↪ When wearing the [autofill anchor mantle](#)<sup>p604</sup>...

When the [autofill field name](#)<sup>p610</sup> is not the empty string, then the user agent must act as if the user had specified the [control's data](#)<sup>p613</sup> for the given [autofill hint set](#)<sup>p610</sup>, [autofill scope](#)<sup>p610</sup>, and [autofill field name](#)<sup>p610</sup> combination.

When the user agent **autofills form controls**, elements with the same [form owner](#)<sup>p598</sup> and the same [autofill scope](#)<sup>p610</sup> must use data relating to the same person, address, payment instrument, and contact details. When a user agent autofills "[country](#)<sup>p607</sup>" and "[country-name](#)<sup>p608</sup>" fields with the same [form owner](#)<sup>p598</sup> and [autofill scope](#)<sup>p610</sup>, and the user agent has a value for the [country](#)<sup>p607</sup>" field(s), then the "[country-name](#)<sup>p608</sup>" field(s) must be filled using a human-readable name for the same country. When a user agent fills in multiple fields at once, all fields with the same [autofill field name](#)<sup>p610</sup>, [form owner](#)<sup>p598</sup> and [autofill scope](#)<sup>p610</sup> must be filled with the same value.

#### Example

Suppose a user agent knows of two phone numbers, +1 555 123 1234 and +1 555 666 7777. It would not be conforming for the user agent to fill a field with `autocomplete="shipping tel-local-prefix"` with the value "123" and another field in the same form with `autocomplete="shipping tel-local-suffix"` with the value "7777". The only valid prefilled values given the aforementioned information would be "123" and "1234", or "666" and "7777", respectively.

### Example

Similarly, if a form for some reason contained both a "[cc-exp](#)<sup>p688</sup>" field and a "[cc-exp-month](#)<sup>p688</sup>" field, and the user agent prefilled the form, then the month component of the former would have to match the latter.

### Example

This requirement interacts with the [autofill anchor mantle](#)<sup>p604</sup> also. Consider the following markup snippet:

```
<form>
  <input type=hidden autocomplete="nickname" value="TreePlate">
  <input type=text autocomplete="nickname">
</form>
```

The only value that a conforming user agent could suggest in the text control is "TreePlate", the value given by the hidden [input](#)<sup>p529</sup> element.

The "section-\*" tokens in the [autofill scope](#)<sup>p610</sup> are opaque; user agents must not attempt to derive meaning from the precise values of these tokens.

### Example

For example, it would not be conforming if the user agent decided that it should offer the address it knows to be the user's daughter's address for "section-child" and the addresses it knows to be the user's spouses' addresses for "section-spouse".

The autocompletion mechanism must be implemented by the user agent acting as if the user had modified the [control's data](#)<sup>p613</sup>, and must be done at a time where the element is [mutable](#)<sup>p597</sup> (e.g. just after the element has been inserted into the document, or when the user agent [stops parsing](#)<sup>p1358</sup>). User agents must only prefill controls using values that the user could have entered.

### Example

For example, if a [select](#)<sup>p568</sup> element only has [option](#)<sup>p577</sup> elements with values "Steve" and "Rebecca", "Jay", and "Bob", and has an [autofill field name](#)<sup>p610</sup> "[given-name](#)<sup>p687</sup>", but the user agent's only idea for what to prefill the field with is "Evan", then the user agent cannot prefill the field. It would not be conforming to somehow set the [select](#)<sup>p568</sup> element to the value "Evan", since the user could not have done so themselves.

A user agent prefilling a form control must not discriminate between form controls that are [in a document tree](#) and those that are [connected](#); that is, it is not conforming to make the decision on whether or not to autofill based on whether the element's [root](#) is a [shadow root](#) versus a [Document](#)<sup>p139</sup>.

A user agent prefilling a form control's [value](#)<sup>p597</sup> must not cause that control to [suffer from a type mismatch](#)<sup>p622</sup>, [suffer from being too long](#)<sup>p623</sup>, [suffer from being too short](#)<sup>p623</sup>, [suffer from an underflow](#)<sup>p623</sup>, [suffer from an overflow](#)<sup>p623</sup>, or [suffer from a step mismatch](#)<sup>p623</sup>. A user agent prefilling a form control's [value](#)<sup>p597</sup> must not cause that control to [suffer from a pattern mismatch](#)<sup>p622</sup> either. Where possible given the control's constraints, user agents must use the format given as canonical in the aforementioned table. Where it's not possible for the canonical format to be used, user agents should use heuristics to attempt to convert values so that they can be used.

### Example

For example, if the user agent knows that the user's middle name is "Ines", and attempts to prefill a form control that looks like this:

```
<input name=middle-initial maxlength=1 autocomplete="additional-name">
```

...then the user agent could convert "Ines" to "I" and prefill it that way.

### Example

A more elaborate example would be with month values. If the user agent knows that the user's birthday is the 27th of July 2012, then it might try to prefill all of the following controls with slightly different values, all driven from this information:

```
<input name=b
type=month
autocomplete="bday">
```

2012-07	The day is dropped since the <a href="#">Month</a> <sup>p533</sup> state only accepts a month/year combination. (Note that this example is non-conforming, because the <a href="#">autofill field name</a> <sup>p610</sup> <a href="#">bday</a> <sup>p688</sup> is not allowed with the <a href="#">Month</a> <sup>p533</sup> state.)
---------	---

<pre>&lt;select name=c autocomplete="bday"&gt;   &lt;option&gt;Jan   &lt;option&gt;Feb   ...   &lt;option&gt;Jul   &lt;option&gt;Aug   ... &lt;/select&gt;</pre>	July	The user agent picks the month from the listed options, either by noticing there are twelve options and picking the 7th, or by recognizing that one of the strings (three characters "Jul" followed by a newline and a space) is a close match for the name of the month (July) in one of the user agent's supported languages, or through some other similar mechanism.
<pre>&lt;input name=a type=number min=1 max=12 autocomplete="bday- month"&gt;</pre>	7	User agent converts "July" to a month number in the range 1..12, like the field.
<pre>&lt;input name=a type=number min=0 max=11 autocomplete="bday- month"&gt;</pre>	6	User agent converts "July" to a month number in the range 0..11, like the field.
<pre>&lt;input name=a type=number min=1 max=11 autocomplete="bday- month"&gt;</pre>		User agent doesn't fill in the field, since it can't make a good guess as to what the form expects.

A user agent may allow the user to override an element's [autofill field name](#)<sup>p610</sup>, e.g. to change it from "[off](#)<sup>p606</sup>" to "[on](#)<sup>p606</sup>" to allow values to be remembered and prefilled despite the page author's objections, or to always "[off](#)<sup>p606</sup>", never remembering values.

More specifically, user agents may in particular consider replacing the [autofill field name](#)<sup>p610</sup> of form controls that match the description given in the first column of the following table, when their [autofill field name](#)<sup>p610</sup> is either "[on](#)<sup>p606</sup>" or "[off](#)<sup>p606</sup>", with the value given in the second cell of that row. If this table is used, the replacements must be done in [tree order](#), since all but the first row references the [autofill field name](#)<sup>p610</sup> of earlier elements. When the descriptions below refer to form controls being preceded or followed by others, they mean in the list of [listed elements](#)<sup>p513</sup> that share the same [form owner](#)<sup>p598</sup>.

Form control	New <a href="#">autofill field name</a> <sup>p610</sup>
an <a href="#">input</a> <sup>p520</sup> element whose <a href="#">type</a> <sup>p523</sup> attribute is in the <a href="#">Text</a> <sup>p527</sup> state that is followed by an <a href="#">input</a> <sup>p520</sup> element whose <a href="#">type</a> <sup>p523</sup> attribute is in the <a href="#">Password</a> <sup>p531</sup> state	" <a href="#">username</a> <sup>p607</sup> "
an <a href="#">input</a> <sup>p520</sup> element whose <a href="#">type</a> <sup>p523</sup> attribute is in the <a href="#">Password</a> <sup>p531</sup> state that is preceded by an <a href="#">input</a> <sup>p520</sup> element whose <a href="#">autofill field name</a> <sup>p610</sup> is " <a href="#">username</a> <sup>p607</sup> "	" <a href="#">current-password</a> <sup>p607</sup> "
an <a href="#">input</a> <sup>p520</sup> element whose <a href="#">type</a> <sup>p523</sup> attribute is in the <a href="#">Password</a> <sup>p531</sup> state that is preceded by an <a href="#">input</a> <sup>p520</sup> element whose <a href="#">autofill field name</a> <sup>p610</sup> is " <a href="#">current-password</a> <sup>p607</sup> "	" <a href="#">new-password</a> <sup>p607</sup> "
an <a href="#">input</a> <sup>p520</sup> element whose <a href="#">type</a> <sup>p523</sup> attribute is in the <a href="#">Password</a> <sup>p531</sup> state that is preceded by an <a href="#">input</a> <sup>p520</sup> element whose <a href="#">autofill field name</a> <sup>p610</sup> is " <a href="#">new-password</a> <sup>p607</sup> "	" <a href="#">new-password</a> <sup>p607</sup> "

The **autocomplete** IDL attribute, on getting, must return the element's [IDL-exposed autofill value](#)<sup>p610</sup>, and on setting, must [reflect](#)<sup>p104</sup> the content attribute of the same name.

#### 4.10.19 APIs for the text control selections §<sup>p61</sup><sub>7</sub>

The [input](#)<sup>p520</sup> and [textarea](#)<sup>p579</sup> elements define several attributes and methods for handling their selection. Their shared algorithms are defined here.

For web developers (non-normative)

**`element.select`<sup>p619</sup>`()`**  
Selects everything in the text control.

**`element.selectionStart`**<sup>p619</sup> [ = *value* ]

Returns the offset to the start of the selection.

Can be set, to change the start of the selection.

**`element.selectionEnd`**<sup>p620</sup> [ = *value* ]

Returns the offset to the end of the selection.

Can be set, to change the end of the selection.

**`element.selectionDirection`**<sup>p620</sup> [ = *value* ]

Returns the current direction of the selection.

Can be set, to change the direction of the selection.

The possible values are "forward", "backward", and "none".

**`element.setSelectionRange`**<sup>p620</sup>(*start*, *end* [, *direction*])

Changes the selection to cover the given substring in the given direction. If the direction is omitted, it will be reset to be the platform default (none or forward).

**`element.setRangeText`**<sup>p621</sup>(*replacement* [, *start*, *end* [, *selectionMode* ] ])

Replaces a range of text with the new text. If the *start* and *end* arguments are not provided, the range is assumed to be the selection.

The final argument determines how the selection will be set after the text has been replaced. The possible values are:

**`"select"`**<sup>p621</sup>

Selects the newly inserted text.

**`"start"`**<sup>p621</sup>

Moves the selection to just before the inserted text.

**`"end"`**<sup>p621</sup>

Moves the selection to just after the selected text.

**`"preserve"`**<sup>p621</sup>

Attempts to preserve the selection. This is the default.

All **`input`**<sup>p520</sup> elements to which these APIs **`apply`**<sup>p523</sup>, and all **`textarea`**<sup>p579</sup> elements, have either a **selection** or a **text entry cursor position** at all times (even for elements that are not **`being rendered`**<sup>p1388</sup>), measured in offsets into the **`code units`** of the control's **`relevant value`**<sup>p618</sup>. The initial state must consist of a **`text entry cursor`**<sup>p618</sup> at the beginning of the control.

For **`input`**<sup>p520</sup> elements, these APIs must operate on the element's **`value`**<sup>p597</sup>. For **`textarea`**<sup>p579</sup> elements, these APIs must operate on the element's **`API value`**<sup>p597</sup>. In the below algorithms, we call the value string being operated on the **relevant value**.

#### Example

The use of **`API value`**<sup>p597</sup> instead of **`raw value`**<sup>p581</sup> for **`textarea`**<sup>p579</sup> elements means that U+000D (CR) characters are normalized away. For example,

```
<textarea id="demo"></textarea>
<script>
  demo.value = "A\r\nB";
  demo.setRangeText("replaced", 0, 2);
  assert(demo.value === "replacedB");
</script>
```

If we had operated on the **`raw value`**<sup>p581</sup> of "A\r\nB", then we would have replaced the characters "A\r", ending up with a result of "replaced\nB". But since we used the **`API value`**<sup>p597</sup> of "A\nB", we replaced the characters "A\n", giving "replacédB".

#### Note

*Characters with no visible rendering, such as U+200D ZERO WIDTH JOINER, still count as characters. Thus, for instance, the selection can include just an invisible character, and the text insertion cursor can be placed to one side or another of such a character.*

Whenever the **`relevant value`**<sup>p618</sup> changes for an element to which these APIs apply, run these steps:

1. If the element has a [selection](#)<sup>p618</sup>:
  1. If the start of the selection is now past the end of the [relevant value](#)<sup>p618</sup>, set it to the end of the [relevant value](#)<sup>p618</sup>.
  2. If the end of the selection is now past the end of the [relevant value](#)<sup>p618</sup>, set it to the end of the [relevant value](#)<sup>p618</sup>.
  3. If the user agent does not support empty selection, and both the start and end of the selection are now pointing to the end of the [relevant value](#)<sup>p618</sup>, then instead set the element's [text entry cursor position](#)<sup>p618</sup> to the end of the [relevant value](#)<sup>p618</sup>, removing any selection.
2. Otherwise, the element must have a [text entry cursor position](#)<sup>p618</sup> position. If it is now past the end of the [relevant value](#)<sup>p618</sup>, set it to the end of the [relevant value](#)<sup>p618</sup>.

#### Note

*In some cases where the [relevant value](#)<sup>p618</sup> changes, other parts of the specification will also modify the [text entry cursor position](#)<sup>p618</sup>, beyond just the clamping steps above. For example, see the [value](#)<sup>p583</sup> setter for [textarea](#)<sup>p579</sup>.*

Where possible, user interface features for changing the [text selection](#)<sup>p618</sup> in [input](#)<sup>p520</sup> and [textarea](#)<sup>p579</sup> elements must be implemented using the [set the selection range](#)<sup>p620</sup> algorithm so that, e.g., all the same events fire.

The [selections](#)<sup>p618</sup> of [input](#)<sup>p520</sup> and [textarea](#)<sup>p579</sup> elements have a **selection direction**, which is either "forward", "backward", or "none". The exact meaning of the selection direction depends on the platform. This direction is set when the user manipulates the selection. The initial [selection direction](#)<sup>p619</sup> must be "none" if the platform supports that direction, or "forward" otherwise.

To **set the selection direction** of an element to a given direction, update the element's [selection direction](#)<sup>p619</sup> to the given direction, unless the direction is "none" and the platform does not support that direction; in that case, update the element's [selection direction](#)<sup>p619</sup> to "forward".

#### Note

*On Windows, the direction indicates the position of the caret relative to the selection: a "forward" selection has the caret at the end of the selection and a "backward" selection has the caret at the start of the selection. Windows has no "none" direction.*

*On Mac, the direction indicates which end of the selection is affected when the user adjusts the size of the selection using the arrow keys with the Shift modifier: the "forward" direction means the end of the selection is modified, and the "backward" direction means the start of the selection is modified. The "none" direction is the default on Mac, it indicates that no particular direction has yet been selected. The user sets the direction implicitly when first adjusting the selection, based on which directional arrow key was used.*

The **select()** method, when invoked, must run the following steps:

1. If this element is an [input](#)<sup>p520</sup> element, and either [select\(\)](#)<sup>p619</sup> **does not apply**<sup>p524</sup> to this element or the corresponding control has no selectable text, return.

#### Example

For instance, in a user agent where `<input type=color>`<sup>p541</sup> is rendered as a color well with a picker, as opposed to a text control accepting a hexadecimal color code, there would be no selectable text, and thus calls to the method are ignored.

2. [Set the selection range](#)<sup>p620</sup> with 0 and infinity.

The **selectionStart** attribute's getter must run the following steps:

1. If this element is an [input](#)<sup>p520</sup> element, and [selectionStart](#)<sup>p619</sup> **does not apply**<sup>p524</sup> to this element, return null.
2. If there is no [selection](#)<sup>p618</sup>, return the [code unit](#) offset within the [relevant value](#)<sup>p618</sup> to the character that immediately follows the [text entry cursor](#)<sup>p618</sup>.
3. Return the [code unit](#) offset within the [relevant value](#)<sup>p618</sup> to the character that immediately follows the start of the [selection](#)<sup>p618</sup>.

The [selectionStart](#)<sup>p619</sup> attribute's setter must run the following steps:

1. If this element is an [input](#)<sup>p520</sup> element, and [selectionStart](#)<sup>p619</sup> **does not apply**<sup>p524</sup> to this element, throw an **"InvalidStateError"** **DOMException**.

2. Let *end* be the value of this element's [selectionEnd](#)<sup>p620</sup> attribute.
3. If *end* is less than the given value, set *end* to the given value.
4. [Set the selection range](#)<sup>p620</sup> with the given value, *end*, and the value of this element's [selectionDirection](#)<sup>p620</sup> attribute.

The [selectionEnd](#) attribute's getter must run the following steps:

1. If this element is an [input](#)<sup>p520</sup> element, and [selectionEnd](#)<sup>p620</sup> [does not apply](#)<sup>p524</sup> to this element, return null.
2. If there is no [selection](#)<sup>p618</sup>, return the [code unit](#) offset within the [relevant value](#)<sup>p618</sup> to the character that immediately follows the [text entry cursor](#)<sup>p618</sup>.
3. Return the [code unit](#) offset within the [relevant value](#)<sup>p618</sup> to the character that immediately follows the end of the [selection](#)<sup>p618</sup>.

The [selectionEnd](#)<sup>p620</sup> attribute's setter must run the following steps:

1. If this element is an [input](#)<sup>p520</sup> element, and [selectionEnd](#)<sup>p620</sup> [does not apply](#)<sup>p524</sup> to this element, throw an ["InvalidStateError" DOMException](#).
2. [Set the selection range](#)<sup>p620</sup> with the value of this element's [selectionStart](#)<sup>p619</sup> attribute, the given value, and the value of this element's [selectionDirection](#)<sup>p620</sup> attribute.

The [selectionDirection](#) attribute's getter must run the following steps:

1. If this element is an [input](#)<sup>p520</sup> element, and [selectionDirection](#)<sup>p620</sup> [does not apply](#)<sup>p524</sup> to this element, return null.
2. Return this element's [selection direction](#)<sup>p619</sup>.

The [selectionDirection](#)<sup>p620</sup> attribute's setter must run the following steps:

1. If this element is an [input](#)<sup>p520</sup> element, and [selectionDirection](#)<sup>p620</sup> [does not apply](#)<sup>p524</sup> to this element, throw an ["InvalidStateError" DOMException](#).
2. [Set the selection range](#)<sup>p620</sup> with the value of this element's [selectionStart](#)<sup>p619</sup> attribute, the value of this element's [selectionEnd](#)<sup>p620</sup> attribute, and the given value.

The [setSelectionRange\(start, end, direction\)](#) method, when invoked, must run the following steps:

1. If this element is an [input](#)<sup>p520</sup> element, and [setSelectionRange\(\)](#)<sup>p620</sup> [does not apply](#)<sup>p524</sup> to this element, throw an ["InvalidStateError" DOMException](#).
2. [Set the selection range](#)<sup>p620</sup> with *start*, *end*, and *direction*.

To **set the selection range** with an integer or null *start*, an integer or null or the special value infinity *end*, and optionally a string *direction*, run the following steps:

1. If *start* is null, let *start* be zero.
2. If *end* is null, let *end* be zero.
3. Set the [selection](#)<sup>p618</sup> of the text control to the sequence of [code units](#) within the [relevant value](#)<sup>p618</sup> starting with the code unit at the *start*th position (in logical order) and ending with the code unit at the (*end*-1)th position. Arguments greater than the [length](#) of the [relevant value](#)<sup>p618</sup> of the text control (including the special value infinity) must be treated as pointing at the end of the text control. If *end* is less than or equal to *start* then the start of the selection and the end of the selection must both be placed immediately before the character with offset *end*. In UAs where there is no concept of an empty selection, this must set the cursor to be just before the character with offset *end*.
4. If *direction* is not [identical to](#) either "backward" or "forward", or if the *direction* argument was not given, set *direction* to "none".
5. [Set the selection direction](#)<sup>p619</sup> of the text control to *direction*.
6. If the previous steps caused the [selection](#)<sup>p618</sup> of the text control to be modified (in either extent or [direction](#)<sup>p619</sup>), then [queue an element task](#)<sup>p1125</sup> on the [user interaction task source](#)<sup>p1134</sup> given the element to [fire an event](#) named [select](#)<sup>p1472</sup> at the element, with the [bubbles](#) attribute initialized to true.

The `setRangeText(replacement, start, end, selectMode)` method, when invoked, must run the following steps:

1. If this element is an `input`<sup>p528</sup> element, and `setRangeText()`<sup>p621</sup> **does not apply**<sup>p524</sup> to this element, throw an `"InvalidStateError"` `DOMException`.
2. Set this element's `dirty value flag`<sup>p597</sup> to true.
3. If the method has only one argument, then let *start* and *end* have the values of the `selectionStart`<sup>p619</sup> attribute and the `selectionEnd`<sup>p620</sup> attribute respectively.  
Otherwise, let *start*, *end* have the values of the second and third arguments respectively.
4. If *start* is greater than *end*, then throw an `"IndexSizeError"` `DOMException`.
5. If *start* is greater than the `length` of the `relevant value`<sup>p618</sup> of the text control, then set it to the `length` of the `relevant value`<sup>p618</sup> of the text control.
6. If *end* is greater than the `length` of the `relevant value`<sup>p618</sup> of the text control, then set it to the `length` of the `relevant value`<sup>p618</sup> of the text control.
7. Let *selection start* be the current value of the `selectionStart`<sup>p619</sup> attribute.
8. Let *selection end* be the current value of the `selectionEnd`<sup>p620</sup> attribute.
9. If *start* is less than *end*, delete the sequence of `code units` within the element's `relevant value`<sup>p618</sup> starting with the code unit at the *start*th position and ending with the code unit at the (*end*-1)th position.
10. Insert the value of the first argument into the text of the `relevant value`<sup>p618</sup> of the text control, immediately before the *start*th `code unit`.
11. Let *new length* be the `length` of the value of the first argument.
12. Let *new end* be the sum of *start* and *new length*.
13. Run the appropriate set of substeps from the following list:
  - ↪ **If the fourth argument's value is "select"**  
Let *selection start* be *start*.  
Let *selection end* be *new end*.
  - ↪ **If the fourth argument's value is "start"**  
Let *selection start* and *selection end* be *start*.
  - ↪ **If the fourth argument's value is "end"**  
Let *selection start* and *selection end* be *new end*.
  - ↪ **If the fourth argument's value is "preserve"**
  - ↪ **If the method has only one argument**
    1. Let *old length* be *end* minus *start*.
    2. Let *delta* be *new length* minus *old length*.
    3. If *selection start* is greater than *end*, then increment it by *delta*. (If *delta* is negative, i.e. the new text is shorter than the old text, then this will *decrease* the value of *selection start*.)  
  
Otherwise: if *selection start* is greater than *start*, then set it to *start*. (This snaps the start of the selection to the start of the new text if it was in the middle of the text that it replaced.)
    4. If *selection end* is greater than *end*, then increment it by *delta* in the same way.  
  
Otherwise: if *selection end* is greater than *start*, then set it to *new end*. (This snaps the end of the selection to the end of the new text if it was in the middle of the text that it replaced.)
14. **Set the selection range**<sup>p620</sup> with *selection start* and *selection end*.

The `setRangeText()`<sup>p621</sup> method uses the following enumeration:

```
IDL enum SelectionMode {
    "select",
    "start",
    "end",
    "preserve" // default
};
```

#### Example

To obtain the currently selected text, the following JavaScript suffices:

```
var selectionText = control.value.substring(control.selectionStart, control.selectionEnd);
```

...where *control* is the [input](#)<sup>p520</sup> or [textarea](#)<sup>p579</sup> element.

#### Example

To add some text at the start of a text control, while maintaining the text selection, the three attributes must be preserved:

```
var oldStart = control.selectionStart;
var oldEnd = control.selectionEnd;
var oldDirection = control.selectionDirection;
var prefix = "http://";
control.value = prefix + control.value;
control.setSelectionRange(oldStart + prefix.length, oldEnd + prefix.length, oldDirection);
```

...where *control* is the [input](#)<sup>p520</sup> or [textarea](#)<sup>p579</sup> element.

## 4.10.20 Constraints <sup>§ p62</sup>

### 4.10.20.1 Definitions <sup>§ p62</sup>

A [submittable element](#)<sup>p514</sup> is a **candidate for constraint validation** except when a condition has **barred the element from constraint validation**. (For example, an element is [barred from constraint validation](#)<sup>p622</sup> if it has a [datalist](#)<sup>p574</sup> element ancestor.)

An element can have a **custom validity error message** defined. Initially, an element must have its [custom validity error message](#)<sup>p622</sup> set to the empty string. When its value is not the empty string, the element is [suffering from a custom error](#)<sup>p623</sup>. It can be set using the [setCustomValidity\(\)](#)<sup>p625</sup> method, except for [form-associated custom elements](#)<sup>p760</sup>. [Form-associated custom elements](#)<sup>p760</sup> can have a [custom validity error message](#)<sup>p622</sup> set via their [ElementInternals](#)<sup>p771</sup> object's [setValidity\(\)](#)<sup>p773</sup> method. The user agent should use the [custom validity error message](#)<sup>p622</sup> when alerting the user to the problem with the control.

An element can be constrained in various ways. The following is the list of **validity states** that a form control can be in, making the control invalid for the purposes of constraint validation. (The definitions below are non-normative; other parts of this specification define more precisely when each state applies or does not.)

#### **Suffering from being missing**

When a control has no [value](#)<sup>p597</sup> but has a `required` attribute ([input](#)<sup>p520</sup> [required](#)<sup>p552</sup>, [textarea](#)<sup>p579</sup> [required](#)<sup>p582</sup>); or, more complicated rules for [select](#)<sup>p568</sup> elements and controls in [radio button groups](#)<sup>p543</sup>, as specified in their sections.

When the [setValidity\(\)](#)<sup>p773</sup> method sets `valueMissing` flag to true for a [form-associated custom element](#)<sup>p760</sup>.

#### **Suffering from a type mismatch**

When a control that allows arbitrary user input has a [value](#)<sup>p597</sup> that is not in the correct syntax ([Email](#)<sup>p530</sup>, [URL](#)<sup>p529</sup>).

When the [setValidity\(\)](#)<sup>p773</sup> method sets `typeMismatch` flag to true for a [form-associated custom element](#)<sup>p760</sup>.

#### **Suffering from a pattern mismatch**

When a control has a [value](#)<sup>p597</sup> that doesn't satisfy the [pattern](#)<sup>p554</sup> attribute.

When the `setValidity()`<sup>p773</sup> method sets `patternMismatch` flag to true for a [form-associated custom element](#)<sup>p760</sup>.

#### **Suffering from being too long**

When a control has a [value](#)<sup>p597</sup> that is too long for the [form control `maxlength` attribute](#)<sup>p600</sup> ([input](#)<sup>p520</sup> [maxlength](#)<sup>p551</sup>, [textarea](#)<sup>p579</sup> [maxlength](#)<sup>p582</sup>).

When the `setValidity()`<sup>p773</sup> method sets `tooLong` flag to true for a [form-associated custom element](#)<sup>p760</sup>.

#### **Suffering from being too short**

When a control has a [value](#)<sup>p597</sup> that is too short for the [form control `minlength` attribute](#)<sup>p601</sup> ([input](#)<sup>p520</sup> [minlength](#)<sup>p551</sup>, [textarea](#)<sup>p579</sup> [minlength](#)<sup>p582</sup>).

When the `setValidity()`<sup>p773</sup> method sets `tooShort` flag to true for a [form-associated custom element](#)<sup>p760</sup>.

#### **Suffering from an underflow**

When a control has a [value](#)<sup>p597</sup> that is not the empty string and is too low for the [min](#)<sup>p555</sup> attribute.

When the `setValidity()`<sup>p773</sup> method sets `rangeUnderflow` flag to true for a [form-associated custom element](#)<sup>p760</sup>.

#### **Suffering from an overflow**

When a control has a [value](#)<sup>p597</sup> that is not the empty string and is too high for the [max](#)<sup>p555</sup> attribute.

When the `setValidity()`<sup>p773</sup> method sets `rangeOverflow` flag to true for a [form-associated custom element](#)<sup>p760</sup>.

#### **Suffering from a step mismatch**

When a control has a [value](#)<sup>p597</sup> that doesn't fit the rules given by the [step](#)<sup>p556</sup> attribute.

When the `setValidity()`<sup>p773</sup> method sets `stepMismatch` flag to true for a [form-associated custom element](#)<sup>p760</sup>.

#### **Suffering from bad input**

When a control has incomplete input and the user agent does not think the user ought to be able to submit the form in its current state.

When the `setValidity()`<sup>p773</sup> method sets `badInput` flag to true for a [form-associated custom element](#)<sup>p760</sup>.

#### **Suffering from a custom error**

When a control's [custom validity error message](#)<sup>p622</sup> (as set by the element's `setCustomValidity()`<sup>p625</sup> method or [ElementInternals](#)<sup>p771</sup>'s `setValidity()`<sup>p773</sup> method) is not the empty string.

#### **Note**

*An element can still suffer from these states even when the element is [disabled](#)<sup>p601</sup>; thus these states can be represented in the DOM even if validating the form during submission wouldn't indicate a problem to the user.*

An element **satisfies its constraints** if it is not suffering from any of the above [validity states](#)<sup>p622</sup>.

### **4.10.20.2 Constraint validation** §<sup>p62</sup><sub>3</sub>

When the user agent is required to **statically validate the constraints** of [form](#)<sup>p514</sup> element *form*, it must run the following steps, which return either a *positive* result (all the controls in the form are valid) or a *negative* result (there are invalid controls) along with a (possibly empty) list of elements that are invalid and for which no script has claimed responsibility:

1. Let *controls* be a list of all the [submittable elements](#)<sup>p514</sup> whose [form owner](#)<sup>p598</sup> is *form*, in [tree order](#).
2. Let *invalid controls* be an initially empty list of elements.
3. For each element *field* in *controls*, in [tree order](#):
  1. If *field* is not a [candidate for constraint validation](#)<sup>p622</sup>, then move on to the next element.
  2. Otherwise, if *field* [satisfies its constraints](#)<sup>p623</sup>, then move on to the next element.
  3. Otherwise, add *field* to *invalid controls*.

4. If *invalid controls* is empty, then return a *positive* result.
5. Let *unhandled invalid controls* be an initially empty list of elements.
6. For each element *field* in *invalid controls*, if any, in [tree order](#):
  1. Let *notCanceled* be the result of [firing an event](#) named [invalid](#)<sup>p1471</sup> at *field*, with the [cancelable](#) attribute initialized to true.
  2. If *notCanceled* is true, then add *field* to *unhandled invalid controls*.
7. Return a *negative* result with the list of elements in the *unhandled invalid controls* list.

If a user agent is to **interactively validate the constraints** of [form](#)<sup>p514</sup> element *form*, then the user agent must run the following steps:

1. [Statically validate the constraints](#)<sup>p623</sup> of *form*, and let *unhandled invalid controls* be the list of elements returned if the result was *negative*.
2. If the result was *positive*, then return that result.
3. Report the problems with the constraints of at least one of the elements given in *unhandled invalid controls* to the user.
  - User agents may focus one of those elements in the process, by running the [focusing steps](#)<sup>p842</sup> for that element, and may change the scrolling position of the document, or perform some other action that brings the element to the user's attention. For elements that are [form-associated custom elements](#)<sup>p760</sup>, user agents should use their [validation anchor](#)<sup>p773</sup> instead, for the purposes of these actions.
  - User agents may report more than one constraint violation.
  - User agents may coalesce related constraint violation reports if appropriate (e.g. if multiple radio buttons in a [group](#)<sup>p543</sup> are marked as required, only one error need be reported).
  - If one of the controls is not [being rendered](#)<sup>p1388</sup> (e.g. it has the [hidden](#)<sup>p824</sup> attribute set) then user agents may report a script error.
4. Return a *negative* result.

#### 4.10.20.3 The constraint validation API <sup>p62</sup><sub>4</sub>

For web developers (non-normative)

**`element.willValidate`**<sup>p625</sup>

Returns true if the element will be validated when the form is submitted; false otherwise.

**`element.setCustomValidity`**<sup>p625</sup> (*message*)

Sets a custom error, so that the element would fail to validate. The given message is the message to be shown to the user when reporting the problem to the user.

If the argument is the empty string, clears the custom error.

**`element.validity`**<sup>p625</sup>.**`valueMissing`**<sup>p626</sup>

Returns true if the element has no value but is a required field; false otherwise.

**`element.validity`**<sup>p625</sup>.**`typeMismatch`**<sup>p626</sup>

Returns true if the element's value is not in the correct syntax; false otherwise.

**`element.validity`**<sup>p625</sup>.**`patternMismatch`**<sup>p626</sup>

Returns true if the element's value doesn't match the provided pattern; false otherwise.

**`element.validity`**<sup>p625</sup>.**`tooLong`**<sup>p626</sup>

Returns true if the element's value is longer than the provided maximum length; false otherwise.

**`element.validity`**<sup>p625</sup>.**`tooShort`**<sup>p626</sup>

Returns true if the element's value, if it is not the empty string, is shorter than the provided minimum length; false otherwise.

**`element.validityp625.rangeUnderflowp626`**

Returns true if the element's value is lower than the provided minimum; false otherwise.

**`element.validityp625.rangeOverflowp626`**

Returns true if the element's value is higher than the provided maximum; false otherwise.

**`element.validityp625.stepMismatchp626`**

Returns true if the element's value doesn't fit the rules given by the `stepp556` attribute; false otherwise.

**`element.validityp625.badInputp626`**

Returns true if the user has provided input in the user interface that the user agent is unable to convert to a value; false otherwise.

**`element.validityp625.customErrorp626`**

Returns true if the element has a custom error; false otherwise.

**`element.validityp625.validp626`**

Returns true if the element's value has no validity problems; false otherwise.

**`valid = element.checkValidityp627()`**

Returns true if the element's value has no validity problems; false otherwise. Fires an `invalidp1471` event at the element in the latter case.

**`valid = element.reportValidityp627()`**

Returns true if the element's value has no validity problems; otherwise, returns false, fires an `invalidp1471` event at the element, and (if the event isn't canceled) reports the problem to the user.

**`element.validationMessagep627`**

Returns the error message that would be shown to the user if the element was to be checked for validity.

The `willValidate` attribute's getter must return true, if this element is a [candidate for constraint validation<sup>p622</sup>](#), and false otherwise (i.e., false if any conditions are [barring it from constraint validation<sup>p622</sup>](#)).

The `willValidate` attribute of [ElementInternals<sup>p771</sup>](#) interface, on getting, must throw a `"NotSupportedError"` `DOMException` if the [target element<sup>p772</sup>](#) is not a [form-associated custom element<sup>p760</sup>](#). Otherwise, it must return true if the [target element<sup>p772</sup>](#) is a [candidate for constraint validation<sup>p622</sup>](#), and false otherwise.

The `setCustomValidity(error)` method steps are:

1. Set *error* to the result of [normalizing newlines](#) given *error*.
2. Set the [custom validity error message<sup>p622</sup>](#) to *error*.

#### Example

In the following example, a script checks the value of a form control each time it is edited, and whenever it is not a valid value, uses the `setCustomValidity()p625` method to set an appropriate message.

```
<label>Feeling: <input name=f type="text" oninput="check(this)"></label>
<script>
function check(input) {
  if (input.value == "good" ||
      input.value == "fine" ||
      input.value == "tired") {
    input.setCustomValidity('' + input.value + ' is not a feeling.');
```

The `validity` attribute's getter must return a [ValidityState<sup>p626</sup>](#) object that represents the [validity states<sup>p622</sup>](#) of this element. This

object is [live](#)<sup>p47</sup>.

The **validity** attribute of [ElementInternals](#)<sup>p771</sup> interface, on getting, must throw a **"NotSupportedError"** [DOMException](#) if the [target element](#)<sup>p772</sup> is not a [form-associated custom element](#)<sup>p760</sup>. Otherwise, it must return a [ValidityState](#)<sup>p626</sup> object that represents the [validity states](#)<sup>p622</sup> of the [target element](#)<sup>p772</sup>. This object is [live](#)<sup>p47</sup>.

IDL [Exposed=Window]

```
interface ValidityState {
  readonly attribute boolean valueMissing;
  readonly attribute boolean typeMismatch;
  readonly attribute boolean patternMismatch;
  readonly attribute boolean tooLong;
  readonly attribute boolean tooShort;
  readonly attribute boolean rangeUnderflow;
  readonly attribute boolean rangeOverflow;
  readonly attribute boolean stepMismatch;
  readonly attribute boolean badInput;
  readonly attribute boolean customError;
  readonly attribute boolean valid;
};
```

A [ValidityState](#)<sup>p626</sup> object has the following attributes. On getting, they must return true if the corresponding condition given in the following list is true, and false otherwise.

#### valueMissing

The control is [suffering from being missing](#)<sup>p622</sup>.

#### typeMismatch

The control is [suffering from a type mismatch](#)<sup>p622</sup>.

#### patternMismatch

The control is [suffering from a pattern mismatch](#)<sup>p622</sup>.

#### tooLong

The control is [suffering from being too long](#)<sup>p623</sup>.

#### tooShort

The control is [suffering from being too short](#)<sup>p623</sup>.

#### rangeUnderflow

The control is [suffering from an underflow](#)<sup>p623</sup>.

#### rangeOverflow

The control is [suffering from an overflow](#)<sup>p623</sup>.

#### stepMismatch

The control is [suffering from a step mismatch](#)<sup>p623</sup>.

#### badInput

The control is [suffering from bad input](#)<sup>p623</sup>.

#### customError

The control is [suffering from a custom error](#)<sup>p623</sup>.

#### valid

None of the other conditions are true.

The **check validity steps** for an element *element* are:

1. If *element* is a [candidate for constraint validation](#)<sup>p622</sup> and does not [satisfy its constraints](#)<sup>p623</sup>, then:
  1. [Fire an event](#) named [invalid](#)<sup>p1471</sup> at *element*, with the [cancelable](#) attribute initialized to true (though canceling

has no effect).

2. Return false.

2. Return true.

The **checkValidity()** method, when invoked, must run the [check validity steps](#)<sup>p626</sup> on this element.

The **checkValidity()** method of the [ElementInternals](#)<sup>p771</sup> interface must run these steps:

1. Let *element* be this [ElementInternals](#)<sup>p771</sup>'s [target element](#)<sup>p772</sup>.
2. If *element* is not a [form-associated custom element](#)<sup>p760</sup>, then throw a **"NotSupportedError"** [DOMException](#).
3. Run the [check validity steps](#)<sup>p626</sup> on *element*.

The **report validity steps** for an element *element* are:

1. If *element* is a [candidate for constraint validation](#)<sup>p622</sup> and does not [satisfy its constraints](#)<sup>p623</sup>, then:
  1. Let *report* be the result of [firing an event](#) named **invalid**<sup>p1471</sup> at *element*, with the **cancelable** attribute initialized to true.
  2. If *report* is true, then report the problems with the constraints of this element to the user. When reporting the problem with the constraints to the user, the user agent may run the [focusing steps](#)<sup>p842</sup> for *element*, and may change the scrolling position of the document, or perform some other action that brings *element* to the user's attention. User agents may report more than one constraint violation, if *element* suffers from multiple problems at once.
3. Return false.
2. Return true.

The **reportValidity()** method, when invoked, must run the [report validity steps](#)<sup>p627</sup> on this element.

The **reportValidity()** method of the [ElementInternals](#)<sup>p771</sup> interface must run these steps:

1. Let *element* be this [ElementInternals](#)<sup>p771</sup>'s [target element](#)<sup>p772</sup>.
2. If *element* is not a [form-associated custom element](#)<sup>p760</sup>, then throw a **"NotSupportedError"** [DOMException](#).
3. Run the [report validity steps](#)<sup>p627</sup> on *element*.

The **validationMessage** attribute's getter must run these steps:

1. If this element is not a [candidate for constraint validation](#)<sup>p622</sup> or if this element [satisfies its constraints](#)<sup>p623</sup>, then return the empty string.
2. Return a suitably localized message that the user agent would show the user if this were the only form control with a validity constraint problem. If the user agent would not actually show a textual message in such a situation (e.g., it would show a graphical cue instead), then return a suitably localized message that expresses (one or more of) the validity constraint(s) that the control does not satisfy. If the element is a [candidate for constraint validation](#)<sup>p622</sup> and is [suffering from a custom error](#)<sup>p623</sup>, then the [custom validity error message](#)<sup>p622</sup> should be present in the return value.

#### 4.10.20.4 Security <sup>p627</sup>

Servers should not rely on client-side validation. Client-side validation can be intentionally bypassed by hostile users, and unintentionally bypassed by users of older user agents or automated tools that do not implement these features. The constraint validation features are only intended to improve the user experience, not to provide any kind of security mechanism.

#### 4.10.21 Form submission §<sup>p62</sup><sub>8</sub>

##### 4.10.21.1 Introduction §<sup>p62</sup><sub>8</sub>

*This section is non-normative.*

When a form is submitted, the data in the form is converted into the structure specified by the [enctype<sup>p603</sup>](#), and then sent to the destination specified by the [action<sup>p602</sup>](#) using the given [method<sup>p602</sup>](#).

For example, take the following form:

```
<form action="/find.cgi" method=get>
  <input type=text name=t>
  <input type=search name=q>
  <input type=submit>
</form>
```

If the user types in "cats" in the first field and "fur" in the second, and then hits the submit button, then the user agent will load `/find.cgi?t=cats&q=fur`.

On the other hand, consider this form:

```
<form action="/find.cgi" method=post enctype="multipart/form-data">
  <input type=text name=t>
  <input type=search name=q>
  <input type=submit>
</form>
```

Given the same user input, the result on submission is quite different: the user agent instead does an HTTP POST to the given URL, with as the entity body something like the following text:

```
-----kYFr4jNJEgCervE
Content-Disposition: form-data; name="t"

cats
-----kYFr4jNJEgCervE
Content-Disposition: form-data; name="q"

fur
-----kYFr4jNJEgCervE--
```

##### 4.10.21.2 Implicit submission §<sup>p62</sup><sub>8</sub>

A [form<sup>p514</sup>](#) element's **default button** is the first [submit button<sup>p514</sup>](#) in [tree order](#) whose [form owner<sup>p598</sup>](#) is that [form<sup>p514</sup>](#) element.

If the user agent supports letting the user submit a form implicitly (for example, on some platforms hitting the "enter" key while a text control is [focused<sup>p836</sup>](#) implicitly submits the form), then doing so for a form, whose [default button<sup>p628</sup>](#) has [activation behavior](#) and is not [disabled<sup>p601</sup>](#), must cause the user agent to [fire a click event<sup>p1148</sup>](#) at that [default button<sup>p628</sup>](#).

#### Note

*There are pages on the web that are only usable if there is a way to implicitly submit forms, so user agents are strongly encouraged to support this.*

If the form has no [submit button<sup>p514</sup>](#), then the implicit submission mechanism must perform the following steps:

1. If the form has more than one [field that blocks implicit submission<sup>p628</sup>](#), then return.
2. [Submit<sup>p629</sup>](#) the [form<sup>p514</sup>](#) element from the [form<sup>p514</sup>](#) element itself with [userInvolvement<sup>p629</sup>](#) set to "[activation<sup>p1814</sup>](#)".

For the purpose of the previous paragraph, an element is a **field that blocks implicit submission** of a [form<sup>p514</sup>](#) element if it is an [input<sup>p520</sup>](#) element whose [form owner<sup>p598</sup>](#) is that [form<sup>p514</sup>](#) element and whose [type<sup>p523</sup>](#) attribute is in one of the following states: [Text<sup>p527</sup>](#),

#### 4.10.21.3 Form submission algorithm <sup>p62</sup><sub>9</sub>

Each [form<sup>p514</sup>](#) element has a **constructing entry list** boolean, initially false.

Each [form<sup>p514</sup>](#) element has a **firing submission events** boolean, initially false.

To **submit** a [form<sup>p514</sup>](#) element *form* from an element *submitter* (typically a button), given an optional boolean **submitted from** [submit\(\)<sup>p517</sup>](#) *method* (default false) and an optional [user navigation involvement<sup>p1014</sup>](#) **userInvolvement** (default "[none<sup>p1814</sup>](#)"):

1. If *form* [cannot navigate<sup>p309</sup>](#), then return.
2. If *form*'s [constructing entry list<sup>p629</sup>](#) is true, then return.
3. Let *form document* be *form*'s [node document](#).
4. If *form document*'s [active sandboxing flag set<sup>p917</sup>](#) has its [sandboxed forms browsing context flag<sup>p915</sup>](#) set, then return.
5. If *submitted from* [submit\(\)<sup>p517</sup>](#) *method* is false, then:
  1. If *form*'s [firing submission events<sup>p629</sup>](#) is true, then return.
  2. Set *form*'s [firing submission events<sup>p629</sup>](#) to true.
  3. For each element *field* in the list of [submittable elements<sup>p514</sup>](#) whose [form owner<sup>p598</sup>](#) is *form*, set *field*'s [user validity<sup>p597</sup>](#) to true.
  4. If the *submitter* element's [no-validate state<sup>p603</sup>](#) is false, then [interactively validate the constraints<sup>p624</sup>](#) of *form* and examine the result. If the result is negative (i.e., the constraint validation concluded that there were invalid fields and probably informed the user of this), then:
    1. Set *form*'s [firing submission events<sup>p629</sup>](#) to false.
    2. Return.
5. Let *submitterButton* be null if *submitter* is *form*. Otherwise, let *submitterButton* be *submitter*.
6. Let *shouldContinue* be the result of [firing an event](#) named [submit<sup>p1472</sup>](#) at *form* using [SubmitEvent<sup>p636</sup>](#), with the [submitter<sup>p636</sup>](#) attribute initialized to *submitterButton*, the [bubbles](#) attribute initialized to true, and the [cancelable](#) attribute initialized to true.
7. Set *form*'s [firing submission events<sup>p629</sup>](#) to false.
8. If *shouldContinue* is false, then return.
9. If *form* [cannot navigate<sup>p309</sup>](#), then return.

#### Note

[Cannot navigate<sup>p309</sup>](#) is run again as dispatching the [submit<sup>p1472</sup>](#) event could have changed the outcome.

6. Let *encoding* be the result of [picking an encoding for the form<sup>p634</sup>](#).
7. Let *entry list* be the result of [constructing the entry list<sup>p632</sup>](#) with *form*, *submitter*, and *encoding*.
8. [Assert](#): *entry list* is not null.
9. If *form* [cannot navigate<sup>p309</sup>](#), then return.

#### Note

[Cannot navigate<sup>p309</sup>](#) is run again as dispatching the [formdata<sup>p1471</sup>](#) event in [constructing the entry list<sup>p632</sup>](#) could have changed the outcome.

10. Let *method* be the *submitter* element's [method<sup>p602</sup>](#).
11. If *method* is [dialog<sup>p602</sup>](#), then:

1. If *form* does not have an ancestor [dialog](#)<sup>p646</sup> element, then return.
  2. Let *subject* be *form*'s nearest ancestor [dialog](#)<sup>p646</sup> element.
  3. Let *result* be null.
  4. If *submitter* is an [input](#)<sup>p520</sup> element whose [type](#)<sup>p523</sup> attribute is in the [Image Button](#)<sup>p547</sup> state, then:
    1. Let (*x*, *y*) be the [selected coordinate](#)<sup>p548</sup>.
    2. Set *result* to the concatenation of *x*, ",", and *y*.
  5. Otherwise, if *submitter* has a [value](#)<sup>p597</sup>, then set *result* to that [value](#)<sup>p597</sup>.
  6. [Close the dialog](#)<sup>p651</sup> *subject* with *result*.
  7. Return.
12. Let *action* be the *submitter* element's [action](#)<sup>p602</sup>.
  13. If *action* is the empty string, let *action* be the [URL](#) of the *form* document.
  14. Let *parsed action* be the result of [encoding-parsing a URL](#)<sup>p97</sup> given *action*, relative to *submitter*'s [node document](#).
  15. If *parsed action* is failure, then return.
  16. Let *scheme* be the [scheme](#) of *parsed action*.
  17. Let *enctype* be the *submitter* element's [enctype](#)<sup>p603</sup>.
  18. Let *formTarget* be null.
  19. If the *submitter* element is a [submit button](#)<sup>p514</sup> and it has a [formtarget](#)<sup>p603</sup> attribute, then set *formTarget* to the [formtarget](#)<sup>p603</sup> attribute value.
  20. Let *target* be the result of [getting an element's target](#)<sup>p176</sup> given *submitter*'s [form owner](#)<sup>p598</sup> and *formTarget*.
  21. Let *noopener* be the result of [getting an element's noopener](#)<sup>p309</sup> with *form*, *parsed action*, and *target*.
  22. Let *targetNavigable* be the first return value of applying [the rules for choosing a navigable](#)<sup>p997</sup> given *target*, *form*'s [node navigable](#)<sup>p989</sup>, and *noopener*.
  23. If *targetNavigable* is null, then return.
  24. Let *historyHandling* be "[auto](#)<sup>p1014</sup>".
  25. If *form document* equals *targetNavigable*'s [active document](#)<sup>p989</sup>, and *form document* has not yet [completely loaded](#)<sup>p1063</sup>, then set *historyHandling* to "[replace](#)<sup>p1014</sup>".
  26. Select the appropriate row in the table below based on *scheme* as given by the first cell of each row. Then, select the appropriate cell on that row based on *method* as given in the first cell of each column. Then, jump to the steps named in that cell and defined below the table.

	<a href="#">GET</a> <sup>p602</sup>	<a href="#">POST</a> <sup>p602</sup>
http	<a href="#">Mutate action URL</a> <sup>p631</sup>	<a href="#">Submit as entity body</a> <sup>p631</sup>
https	<a href="#">Mutate action URL</a> <sup>p631</sup>	<a href="#">Submit as entity body</a> <sup>p631</sup>
ftp	<a href="#">Get action URL</a> <sup>p631</sup>	<a href="#">Get action URL</a> <sup>p631</sup>
javascript	<a href="#">Get action URL</a> <sup>p631</sup>	<a href="#">Get action URL</a> <sup>p631</sup>
data	<a href="#">Mutate action URL</a> <sup>p631</sup>	<a href="#">Get action URL</a> <sup>p631</sup>
mailto	<a href="#">Mail with headers</a> <sup>p632</sup>	<a href="#">Mail as body</a> <sup>p632</sup>

If *scheme* is not one of those listed in this table, then the behavior is not defined by this specification. User agents should, in the absence of another specification defining this, act in a manner analogous to that defined in this specification for similar schemes.

Each [form](#)<sup>p514</sup> element has a **planned navigation**, which is either null or a [task](#)<sup>p1124</sup>; when the [form](#)<sup>p514</sup> is first created, its [planned navigation](#)<sup>p630</sup> must be set to null. In the behaviors described below, when the user agent is required to **plan to navigate** to a [URL](#) *url* given an optional [POST resource](#)<sup>p1007</sup>-or-null *postResource* (default null), it must run the following steps:

1. Let *referrerPolicy* be the empty string.
2. If the [form<sup>p514</sup>](#) element's [link types<sup>p314</sup>](#) include the [norereferrer<sup>p325</sup>](#) keyword, then set *referrerPolicy* to "no-referrer".
3. If the [form<sup>p514</sup>](#) has a non-null [planned navigation<sup>p630</sup>](#), remove it from its [task queue<sup>p1123</sup>](#).
4. [Queue an element task<sup>p1125</sup>](#) on the [DOM manipulation task source<sup>p1134</sup>](#) given the [form<sup>p514</sup>](#) element and the following steps:
  1. Set the [form<sup>p514</sup>](#)'s [planned navigation<sup>p630</sup>](#) to null.
  2. [Navigate<sup>p1014</sup>](#) *targetNavigable* to *url* using the [form<sup>p514</sup>](#) element's [node document](#), with [historyHandling<sup>p1014</sup>](#) set to *historyHandling*, [userInvolvement<sup>p1014</sup>](#) set to *userInvolvement*, [referrerPolicy<sup>p1014</sup>](#) set to *referrerPolicy*, [documentResource<sup>p1014</sup>](#) set to *postResource*, and [formDataEntryList<sup>p1014</sup>](#) set to *entry list*.
5. Set the [form<sup>p514</sup>](#)'s [planned navigation<sup>p630</sup>](#) to the just-queued [task<sup>p1124</sup>](#).

The behaviors are as follows:

#### **Mutate action URL**

Let *pairs* be the result of [converting to a list of name-value pairs<sup>p634</sup>](#) with *entry list*.

Let *query* be the result of running the [application/x-www-form-urlencoded serializer](#) with *pairs* and *encoding*.

Set *parsed action*'s *query* component to *query*.

[Plan to navigate<sup>p630</sup>](#) to *parsed action*.

#### **Submit as entity body**

**Assert:** method is [POST<sup>p602</sup>](#).

Switch on *enctype*:

↪ [application/x-www-form-urlencoded<sup>p603</sup>](#)

Let *pairs* be the result of [converting to a list of name-value pairs<sup>p634</sup>](#) with *entry list*.

Let *body* be the result of running the [application/x-www-form-urlencoded serializer](#) with *pairs* and *encoding*.

Set *body* to the result of [encoding](#) *body*.

Let *mimeType* be ``application/x-www-form-urlencoded``.

↪ [multipart/form-data<sup>p603</sup>](#)

Let *body* be the result of running the [multipart/form-data encoding algorithm<sup>p635</sup>](#) with *entry list* and *encoding*.

Let *mimeType* be the [isomorphic encoding](#) of the concatenation of "multipart/form-data; boundary=" and the [multipart/form-data boundary string<sup>p635</sup>](#) generated by the [multipart/form-data encoding algorithm<sup>p635</sup>](#).

↪ [text/plain<sup>p603</sup>](#)

Let *pairs* be the result of [converting to a list of name-value pairs<sup>p634</sup>](#) with *entry list*.

Let *body* be the result of running the [text/plain encoding algorithm<sup>p635</sup>](#) with *pairs*.

Set *body* to the result of [encoding](#) *body* using *encoding*.

Let *mimeType* be ``text/plain``.

[Plan to navigate<sup>p630</sup>](#) to *parsed action* given a [POST resource<sup>p1007</sup>](#) whose [request body<sup>p1007</sup>](#) is *body* and [request content-type<sup>p1007</sup>](#) is *mimeType*.

#### **Get action URL**

[Plan to navigate<sup>p630</sup>](#) to *parsed action*.

**Note**

entry list is discarded.

**Mail with headers**

Let *pairs* be the result of [converting to a list of name-value pairs](#)<sup>p634</sup> with *entry list*.

Let *headers* be the result of running the [application/x-www-form-urlencoded serializer](#) with *pairs* and *encoding*.

Replace occurrences of U+002B PLUS SIGN characters (+) in *headers* with the string "%20".

Set *parsed action*'s [query](#) to *headers*.

[Plan to navigate](#)<sup>p630</sup> to *parsed action*.

**Mail as body**

Let *pairs* be the result of [converting to a list of name-value pairs](#)<sup>p634</sup> with *entry list*.

Switch on *enctype*:

↳ [text/plain](#)<sup>p603</sup>

Let *body* be the result of running the [text/plain encoding algorithm](#)<sup>p635</sup> with *pairs*.

Set *body* to the result of running [UTF-8 percent-encode](#) on *body* using the [default encode set](#). [\[URL\]](#)<sup>p1483</sup>

↳ **Otherwise**

Let *body* be the result of running the [application/x-www-form-urlencoded serializer](#) with *pairs* and *encoding*.

If *parsed action*'s [query](#) is null, then set it to the empty string.

If *parsed action*'s [query](#) is not the empty string, then append a single U+0026 AMPERSAND character (&) to it.

Append "body=" to *parsed action*'s [query](#).

Append *body* to *parsed action*'s [query](#).

[Plan to navigate](#)<sup>p630</sup> to *parsed action*.

**4.10.21.4 Constructing the entry list** §<sup>p63</sup><sub>2</sub>

An **entry list** is a [list](#) of [entries](#)<sup>p632</sup>, typically representing the contents of a form. An **entry** is a tuple consisting of a **name** (a [scalar value string](#)) and a **value** (either a [scalar value string](#) or a [File](#) object).

To **create an entry** given a string *name*, a string or [Blob](#) object *value*, and optionally a [scalar value string](#) *filename*:

1. Set *name* to the result of [converting](#) *name* into a [scalar value string](#).
2. If *value* is a string, then set *value* to the result of [converting](#) *value* into a [scalar value string](#).
3. Otherwise:
  1. If *value* is not a [File](#) object, then set *value* to a new [File](#) object, representing the same bytes, whose [name](#) attribute value is "blob".
  2. If *filename* is given, then set *value* to a new [File](#) object, representing the same bytes, whose [name](#) attribute is *filename*.

**Note**

These operations will create a new [File](#) object if either *filename* is given or the passed [Blob](#) is not a [File](#) object. In those cases, the identity of the passed [Blob](#) object is not kept.

4. Return an [entry](#)<sup>p632</sup> whose [name](#)<sup>p632</sup> is *name* and whose [value](#)<sup>p632</sup> is *value*.

To **construct the entry list** given a *form*, an optional *submitter* (default null), and an optional *encoding* (default [UTF-8](#)):

1. If *form*'s [constructing entry list](#)<sup>p629</sup> is true, then return null.
2. Set *form*'s [constructing entry list](#)<sup>p629</sup> to true.
3. Let *controls* be a list of all the [submittable elements](#)<sup>p514</sup> whose [form owner](#)<sup>p598</sup> is *form*, in [tree order](#).
4. Let *entry list* be a new empty [entry list](#)<sup>p632</sup>.
5. For each element *field* in *controls*, in [tree order](#):
  1. If any of the following are true:
    - *field* has a [datalist](#)<sup>p574</sup> element ancestor;
    - *field* is [disabled](#)<sup>p601</sup>;
    - *field* is a [button](#)<sup>p514</sup> but it is not *submitter*;
    - *field* is an [input](#)<sup>p520</sup> element whose [type](#)<sup>p523</sup> attribute is in the [Checkbox](#)<sup>p542</sup> state and whose [checkedness](#)<sup>p597</sup> is false; or
    - *field* is an [input](#)<sup>p520</sup> element whose [type](#)<sup>p523</sup> attribute is in the [Radio Button](#)<sup>p543</sup> state and whose [checkedness](#)<sup>p597</sup> is false,
 then [continue](#).
  2. If the *field* element is an [input](#)<sup>p520</sup> element whose [type](#)<sup>p523</sup> attribute is in the [Image Button](#)<sup>p547</sup> state, then:
    1. If the *field* element is not *submitter*, then [continue](#).
    2. If the *field* element has a [name](#)<sup>p599</sup> attribute specified and its value is not the empty string, let *name* be that value followed by U+002E (.). Otherwise, let *name* be the empty string.
    3. Let *name<sub>x</sub>* be the concatenation of *name* and U+0078 (x).
    4. Let *name<sub>y</sub>* be the concatenation of *name* and U+0079 (y).
    5. Let (x, y) be the [selected coordinate](#)<sup>p548</sup>.
    6. [Create an entry](#)<sup>p632</sup> with *name<sub>x</sub>* and x, and [append](#) it to *entry list*.
    7. [Create an entry](#)<sup>p632</sup> with *name<sub>y</sub>* and y, and [append](#) it to *entry list*.
    8. [Continue](#).
  3. If the *field* is a [form-associated custom element](#)<sup>p760</sup>, then perform the [entry construction algorithm](#)<sup>p774</sup> given *field* and *entry list*, then [continue](#).
  4. If either the *field* element does not have a [name](#)<sup>p599</sup> attribute specified, or its [name](#)<sup>p599</sup> attribute's value is the empty string, then [continue](#).
  5. Let *name* be the value of the *field* element's [name](#)<sup>p599</sup> attribute.
  6. If the *field* element is a [select](#)<sup>p568</sup> element, then for each [option](#)<sup>p577</sup> element in the [select](#)<sup>p568</sup> element's [list of options](#)<sup>p569</sup> whose [selectedness](#)<sup>p578</sup> is true and that is not [disabled](#)<sup>p578</sup>, [create an entry](#)<sup>p632</sup> with *name* and the [value](#)<sup>p578</sup> of the [option](#)<sup>p577</sup> element, and [append](#) it to *entry list*.
  7. Otherwise, if the *field* element is an [input](#)<sup>p520</sup> element whose [type](#)<sup>p523</sup> attribute is in the [Checkbox](#)<sup>p542</sup> state or the [Radio Button](#)<sup>p543</sup> state, then:
    1. If the *field* element has a [value](#)<sup>p525</sup> attribute specified, then let *value* be the value of that attribute; otherwise, let *value* be the string "on".
    2. [Create an entry](#)<sup>p632</sup> with *name* and *value*, and [append](#) it to *entry list*.
  8. Otherwise, if the *field* element is an [input](#)<sup>p520</sup> element whose [type](#)<sup>p523</sup> attribute is in the [File Upload](#)<sup>p544</sup> state, then:
    1. If there are no [selected files](#)<sup>p544</sup>, then [create an entry](#)<sup>p632</sup> with *name* and a new [File](#) object with an empty name, [application/octet-stream](#) as type, and an empty body, and [append](#) it to *entry list*.
    2. Otherwise, for each file in [selected files](#)<sup>p544</sup>, [create an entry](#)<sup>p632</sup> with *name* and a [File](#) object representing

the file, and [append](#) it to *entry list*.

9. Otherwise, if the *field* element is an [input](#)<sup>p520</sup> element whose [type](#)<sup>p523</sup> attribute is in the [Hidden](#)<sup>p527</sup> state and *name* is an [ASCII case-insensitive](#) match for "[\\_charset\\_](#)<sup>p599</sup>":
  1. Let *charset* be the [name](#) of *encoding*.
  2. [Create an entry](#)<sup>p632</sup> with *name* and *charset*, and [append](#) it to *entry list*.
10. Otherwise, [create an entry](#)<sup>p632</sup> with *name* and the [value](#)<sup>p597</sup> of the *field* element, and [append](#) it to *entry list*.
11. If the element has a [dirname](#)<sup>p600</sup> attribute, that attribute's value is not the empty string, and the element is an [auto-directionality form-associated element](#)<sup>p161</sup>:
  1. Let *dirname* be the value of the element's [dirname](#)<sup>p600</sup> attribute.
  2. Let *dir* be the string "ltr" if the [directionality](#)<sup>p160</sup> of the element is '[ltr](#)<sup>p160</sup>', and "rtl" otherwise (i.e., when the [directionality](#)<sup>p160</sup> of the element is '[rtl](#)<sup>p160</sup>').
  3. [Create an entry](#)<sup>p632</sup> with *dirname* and *dir*, and [append](#) it to *entry list*.
6. Let *form data* be a new [FormData](#) object associated with *entry list*.
7. [Fire an event](#) named [formdata](#)<sup>p1471</sup> at *form* using [FormDataEvent](#)<sup>p636</sup>, with the [formData](#)<sup>p636</sup> attribute initialized to *form data* and the [bubbles](#) attribute initialized to true.
8. Set *form*'s [constructing entry list](#)<sup>p629</sup> to false.
9. Return a [clone](#) of *entry list*.

#### 4.10.21.5 Selecting a form submission encoding § p63 4

If the user agent is to **pick an encoding for a form**, it must run the following steps:

1. Let *encoding* be the [document's character encoding](#).
2. If the [form](#)<sup>p514</sup> element has an [accept-charset](#)<sup>p515</sup> attribute, set *encoding* to the return value of running these substeps:
  1. Let *input* be the value of the [form](#)<sup>p514</sup> element's [accept-charset](#)<sup>p515</sup> attribute.
  2. Let *candidate encoding labels* be the result of [splitting input on ASCII whitespace](#).
  3. Let *candidate encodings* be an empty list of [character encodings](#).
  4. For each token in *candidate encoding labels* in turn (in the order in which they were found in *input*), [get an encoding](#) for the token and, if this does not result in failure, append the [encoding](#) to *candidate encodings*.
  5. If *candidate encodings* is empty, return [UTF-8](#).
  6. Return the first encoding in *candidate encodings*.
3. Return the result of [getting an output encoding](#) from *encoding*.

#### 4.10.21.6 Converting an entry list to a list of name-value pairs § p63 4

The [application/x-www-form-urlencoded](#) and [text/plain](#)<sup>p635</sup> encoding algorithms take a list of name-value pairs, where the values must be strings, rather than an [entry list](#)<sup>p632</sup> where the value can be a [File](#). The following algorithm performs the conversion.

To **convert to a list of name-value pairs** an [entry list](#)<sup>p632</sup> *entry list*, run these steps:

1. Let *list* be an empty [list](#) of name-value pairs.
2. [For each](#) entry of *entry list*:
  1. Let *name* be entry's [name](#)<sup>p632</sup>, with every occurrence of U+000D (CR) not followed by U+000A (LF), and every occurrence of U+000A (LF) not preceded by U+000D (CR), replaced by a string consisting of U+000D (CR) and

U+000A (LF).

2. If entry's [value](#)<sup>p632</sup> is a **File** object, then let *value* be entry's [value](#)<sup>p632</sup>'s **name**. Otherwise, let *value* be entry's [value](#)<sup>p632</sup>.
  3. Replace every occurrence of U+000D (CR) not followed by U+000A (LF), and every occurrence of U+000A (LF) not preceded by U+000D (CR), in *value*, by a string consisting of U+000D (CR) and U+000A (LF).
  4. **Append** to *list* a new name-value pair whose name is *name* and whose value is *value*.
3. Return *list*.

#### 4.10.21.7 URL-encoded form data § p63 5

See *URL* for details on [application/x-www-form-urlencoded](#). [\[URL\]](#)<sup>p1483</sup>

#### 4.10.21.8 Multipart form data § p63 5

The **multipart/form-data encoding algorithm**, given an [entry list](#)<sup>p632</sup> *entry list* and an [encoding](#) *encoding*, is as follows:

1. **For each** entry of *entry list*:
  1. Replace every occurrence of U+000D (CR) not followed by U+000A (LF), and every occurrence of U+000A (LF) not preceded by U+000D (CR), in entry's [name](#)<sup>p632</sup>, by a string consisting of a U+000D (CR) and U+000A (LF).
  2. If entry's [value](#)<sup>p632</sup> is not a **File** object, then replace every occurrence of U+000D (CR) not followed by U+000A (LF), and every occurrence of U+000A (LF) not preceded by U+000D (CR), in entry's [value](#)<sup>p632</sup>, by a string consisting of a U+000D (CR) and U+000A (LF).
2. Return the byte sequence resulting from encoding the *entry list* using the rules described by RFC 7578, *Returning Values from Forms: multipart/form-data*, given the following conditions: [\[RFC7578\]](#)<sup>p1482</sup>
  - Each [entry](#)<sup>p632</sup> in *entry list* is a *field*, the [name](#)<sup>p632</sup> of the entry is the *field name* and the [value](#)<sup>p632</sup> of the entry is the *field value*.
  - The order of parts must be the same as the order of fields in *entry list*. Multiple entries with the same name must be treated as distinct fields.
  - Field names, field values for non-file fields, and filenames for file fields, in the generated [multipart/form-data](#)<sup>p1474</sup> resource must be set to the result of [encoding](#) the corresponding entry's name or value with *encoding*, converted to a byte sequence.
  - For field names and filenames for file fields, the result of the encoding in the previous bullet point must be escaped by replacing any 0x0A (LF) bytes with the byte sequence `%0A`, 0x0D (CR) with `%0D` and 0x22 (") with `%22`. The user agent must not perform any other escapes.
  - The parts of the generated [multipart/form-data](#)<sup>p1474</sup> resource that correspond to non-file fields must not have a [Content-Type](#)<sup>p98</sup> header specified.
  - The boundary used by the user agent in generating the return value of this algorithm is the **multipart/form-data boundary string**. (This value is used to generate the MIME type of the form submission payload generated by this algorithm.)

For details on how to interpret [multipart/form-data](#)<sup>p1474</sup> payloads, see RFC 7578. [\[RFC7578\]](#)<sup>p1482</sup>

#### 4.10.21.9 Plain text form data § p63 5

The **text/plain encoding algorithm**, given a list of name-value pairs *pairs*, is as follows:

1. Let *result* be the empty string.
2. For each *pair* in *pairs*:

1. Append *pair*'s name to *result*.
  2. Append a single U+003D EQUALS SIGN character (=) to *result*.
  3. Append *pair*'s value to *result*.
  4. Append a U+000D CARRIAGE RETURN (CR) U+000A LINE FEED (LF) character pair to *result*.
3. Return *result*.

Payloads using the [text/plain](#) format are intended to be human readable. They are not reliably interpretable by computer, as the format is ambiguous (for example, there is no way to distinguish a literal newline in a value from the newline at the end of the value).

#### 4.10.21.10 The [SubmitEvent](#)<sup>p636</sup> interface § p63<sub>6</sub>

IDL [Exposed=[Window](#)]

```
interface SubmitEvent : Event {
  constructor(DOMString type, optional SubmitEventInit eventInitDict = {});

  readonly attribute HTMLElement? submitter;
};

dictionary SubmitEventInit : EventInit {
  HTMLElement? submitter = null;
};
```

##### For web developers (non-normative)

###### [event.submitter](#)<sup>p636</sup>

Returns the element representing the [submit button](#)<sup>p514</sup> that triggered the [form submission](#)<sup>p628</sup>, or null if the submission was not triggered by a button.

The **submitter** attribute must return the value it was initialized to.

#### 4.10.21.11 The [FormDataEvent](#)<sup>p636</sup> interface § p63<sub>6</sub>

IDL [Exposed=[Window](#)]

```
interface FormDataEvent : Event {
  constructor(DOMString type, FormDataEventInit eventInitDict);

  readonly attribute FormData formData;
};

dictionary FormDataEventInit : EventInit {
  required FormData formData;
};
```

##### For web developers (non-normative)

###### [event.formData](#)<sup>p636</sup>

Returns a [FormData](#) object representing names and values of elements associated to the target [form](#)<sup>p514</sup>. Operations on the [FormData](#) object will affect form data to be submitted.

The **formData** attribute must return the value it was initialized to. It represents a [FormData](#) object associated to the [entry list](#)<sup>p632</sup> that is [constructed](#)<sup>p632</sup> when the [form](#)<sup>p514</sup> is submitted.

#### 4.10.22 Resetting a form <sup>§ p63</sup><sub>7</sub>

When a [form](#)<sup>p514</sup> element *form* is **reset**, run these steps:

1. Let *reset* be the result of [firing an event](#) named [reset](#)<sup>p1472</sup> at *form*, with the [bubbles](#) and [cancelable](#) attributes initialized to true.
2. If *reset* is true, then invoke the [reset algorithm](#)<sup>p637</sup> of each [resettable element](#)<sup>p514</sup> whose [form owner](#)<sup>p598</sup> is *form*.

Each [resettable element](#)<sup>p514</sup> defines its own **reset algorithm**. Changes made to form controls as part of these algorithms do not count as changes caused by the user (and thus, e.g., do not cause [input](#) events to fire).

### 4.11 Interactive elements <sup>§ p63</sup><sub>7</sub>

#### 4.11.1 The [details](#) element <sup>§ p63</sup><sub>7</sub>

##### Categories<sup>p146</sup>:

[Flow content](#)<sup>p149</sup>.  
[Interactive content](#)<sup>p150</sup>.  
[Palpable content](#)<sup>p150</sup>.

##### Contexts in which this element can be used<sup>p146</sup>:

Where [flow content](#)<sup>p149</sup> is expected.

##### Content model<sup>p146</sup>:

One [summary](#)<sup>p643</sup> element followed by [flow content](#)<sup>p149</sup>.

##### Tag omission in text/html<sup>p146</sup>:

Neither tag is omissible.

##### Content attributes<sup>p146</sup>:

[Global attributes](#)<sup>p154</sup>  
[name](#)<sup>p638</sup> — Name of group of mutually-exclusive [details](#)<sup>p637</sup> elements  
[open](#)<sup>p638</sup> — Whether the details are visible

##### Accessibility considerations<sup>p146</sup>:

[For authors](#).  
[For implementers](#).

##### DOM interface<sup>p147</sup>:

```
IDL [Exposed=Window]
interface HTMLDetailsElement : HTMLElement {
    [HTMLConstructor] constructor();

    [CEReactions] attribute DOMString name;
    [CEReactions] attribute boolean open;
};
```

The [details](#)<sup>p637</sup> element [represents](#)<sup>p141</sup> a disclosure widget from which the user can obtain additional information or controls.

##### Note

As with all HTML elements, it is not conforming to use the [details](#)<sup>p637</sup> element when attempting to represent another type of control. For example, tab widgets and menu widgets are not disclosure widgets, so abusing the [details](#)<sup>p637</sup> element to implement these patterns is incorrect.

##### Note

The [details](#)<sup>p637</sup> element is not appropriate for footnotes. Please see [the section on footnotes](#)<sup>p779</sup> for details on how to mark up footnotes.

The first [summary](#)<sup>p643</sup> element child of the element, if any, [represents](#)<sup>p141</sup> the summary or legend of the details. If there is no child [summary](#)<sup>p643</sup> element, the user agent should provide its own legend (e.g. "Details").

The rest of the element's contents [represents](#)<sup>p141</sup> the additional information or controls.

The **name** content attribute gives the name of the group of related [details](#)<sup>p637</sup> elements that the element is a member of. Opening one member of this group causes other members of the group to close. If the attribute is specified, its value must not be the empty string.

Before using this feature, authors should consider whether this grouping of related [details](#)<sup>p637</sup> elements into an exclusive accordion is helpful or harmful to users. While using an exclusive accordion can reduce the maximum amount of space that a set of content can occupy, it can also frustrate users who have to open many items to find what they want or users who want to look at the contents of multiple items at the same time.

A document must not contain more than one [details](#)<sup>p637</sup> element in the same [details name group](#)<sup>p638</sup> that has the [open](#)<sup>p638</sup> attribute present. Authors must not use script to add [details](#)<sup>p637</sup> elements to a document in a way that would cause a [details name group](#)<sup>p638</sup> to have more than one [details](#)<sup>p637</sup> element with the [open](#)<sup>p638</sup> attribute present.

#### Note

*The group of elements that is created by a common [name](#)<sup>p638</sup> attribute is exclusive, meaning that at most one of the [details](#)<sup>p637</sup> elements can be open at once. While this exclusivity is enforced by user agents, the resulting enforcement immediately changes the [open](#)<sup>p638</sup> attributes in the markup. This requirement on authors forbids such misleading markup.*

A document must not contain a [details](#)<sup>p637</sup> element that is a descendant of another [details](#)<sup>p637</sup> element in the same [details name group](#)<sup>p638</sup>.

Documents that use the [name](#)<sup>p638</sup> attribute to group multiple related [details](#)<sup>p637</sup> elements should keep those related elements together in a containing element (such as a [section](#)<sup>p209</sup> element or [article](#)<sup>p206</sup> element). When it makes sense for the group to be introduced with a heading, authors should put that heading in a [heading](#)<sup>p224</sup> element at the start of the containing element.

#### Note

*Visually and programmatically grouping related elements together can be important for accessible user experiences. This can help users understand the relationship between such elements. When related elements are in disparate sections of a web page rather than being grouped, the elements' relationships to each other can be less discoverable or understandable.*

The **open** content attribute is a [boolean attribute](#)<sup>p75</sup>. If present, it indicates that both the summary and the additional information is to be shown to the user. If the attribute is absent, only the summary is to be shown.

When the element is created, if the attribute is absent, the additional information should be hidden; if the attribute is present, that information should be shown. Subsequently, if the attribute is removed, then the information should be hidden; if the attribute is added, the information should be shown.

The user agent should allow the user to request that the additional information be shown or hidden. To honor a request for the details to be shown, the user agent must [set](#) the [open](#)<sup>p638</sup> attribute on the element to the empty string. To honor a request for the information to be hidden, the user agent must [remove](#) the [open](#)<sup>p638</sup> attribute from the element.

#### Note

*This ability to request that additional information be shown or hidden may simply be the [activation behavior](#) of the appropriate [summary](#)<sup>p643</sup> element, in the case such an element exists. However, if no such element exists, user agents can still provide this ability through some other user interface affordance.*

The **details name group** that contains a [details](#)<sup>p637</sup> element *a* also contains all the other [details](#)<sup>p637</sup> elements *b* that fulfill all of the following conditions:

- Both *a* and *b* are in the same [tree](#).
- They both have a [name](#)<sup>p638</sup> attribute, their [name](#)<sup>p638</sup> attributes are not the empty string, and the value of *a*'s [name](#)<sup>p638</sup> attribute equals the value of *b*'s [name](#)<sup>p638</sup> attribute.

Every [details](#)<sup>p637</sup> element has a **details toggle task tracker**, which is a [toggle task tracker](#)<sup>p833</sup> or null, initially null.

The following [attribute change steps](#), given *element*, *localName*, *oldValue*, *value*, and *namespace*, are used for all [details](#)<sup>p637</sup> elements:

1. If `namespace` is not null, then return.
2. If `localName` is `namep638`, then [ensure details exclusivity by closing the given element if needed<sup>p639</sup>](#) given `element`.
3. If `localName` is `openp638`, then:
  1. If one of `oldValue` or `value` is null and the other is not null, run the following steps, which are known as the **details notification task steps**, for this `detailsp637` element:

**Note**

*When the `openp638` attribute is toggled several times in succession, the resulting tasks essentially get coalesced so that only one event is fired.*

1. If `oldValue` is null, [queue a details toggle event task<sup>p639</sup>](#) given the `detailsp637` element, "closed", and "open".
2. Otherwise, [queue a details toggle event task<sup>p639</sup>](#) given the `detailsp637` element, "open", and "closed".
2. If `oldValue` is null and `value` is not null, then [ensure details exclusivity by closing other elements if needed<sup>p639</sup>](#) given `element`.

The `detailsp637` [HTML element insertion steps<sup>p45</sup>](#), given `insertedNode`, are:

1. [Ensure details exclusivity by closing the given element if needed<sup>p639</sup>](#) given `insertedNode`.

**Note**

*To be clear, these attribute change and insertion steps also run when an attribute or element is inserted via the parser.*

To **queue a details toggle event task** given a `detailsp637` element `element`, a string `oldState`, and a string `newState`:

1. If `element`'s [details toggle task tracker<sup>p638</sup>](#) is not null, then:
  1. Set `oldState` to `element`'s [details toggle task tracker<sup>p638</sup>](#)'s `old statep833`.
  2. Remove `element`'s [details toggle task tracker<sup>p638</sup>](#)'s `taskp833` from its [task queue<sup>p1123</sup>](#).
  3. Set `element`'s [details toggle task tracker<sup>p638</sup>](#) to null.
2. [Queue an element task<sup>p1125</sup>](#) given the [DOM manipulation task source<sup>p1134</sup>](#) and `element` to run the following steps:
  1. [Fire an event](#) named `togglep1472` at `element`, using [ToggleEvent<sup>p833</sup>](#), with the `oldStatep833` attribute initialized to `oldState` and the `newStatep833` attribute initialized to `newState`.
  2. Set `element`'s [details toggle task tracker<sup>p638</sup>](#) to null.
3. Set `element`'s [details toggle task tracker<sup>p638</sup>](#) to a struct with [task<sup>p833</sup>](#) set to the just-queued [task<sup>p1124</sup>](#) and `old statep833` set to `oldState`.

To **ensure details exclusivity by closing other elements if needed** given a `detailsp637` element `element`:

1. [Assert](#): `element` has an `openp638` attribute.
2. If `element` does not have a `namep638` attribute, or its `namep638` attribute is the empty string, then return.
3. Let `groupMembers` be a list of elements, containing all elements in `element`'s [details name group<sup>p638</sup>](#) except for `element`, in [tree order](#).
4. [For each](#) element `otherElement` of `groupMembers`:
  1. If the `openp638` attribute is set on `otherElement`, then:
    1. [Assert](#): `otherElement` is the only element in `groupMembers` that has the `openp638` attribute set.
    2. [Remove](#) the `openp638` attribute on `otherElement`.
    3. [Break](#).

To **ensure details exclusivity by closing the given element if needed** given a `detailsp637` element `element`:

1. If *element* does not have an `open`<sup>p638</sup> attribute, then return.
2. If *element* does not have a `name`<sup>p638</sup> attribute, or its `name`<sup>p638</sup> attribute is the empty string, then return.
3. Let *groupMembers* be a list of elements, containing all elements in *element*'s `details name group`<sup>p638</sup> except for *element*, in [tree order](#).
4. [For each](#) element *otherElement* of *groupMembers*:
  1. If the `open`<sup>p638</sup> attribute is set on *otherElement*, then:
    1. [Remove](#) the `open`<sup>p638</sup> attribute on *element*.
    2. [Break](#).

The `name` and `open` IDL attributes must [reflect](#)<sup>p104</sup> the respective content attributes of the same name.

The **ancestor details revealing algorithm** is to run the following steps on *currentNode*:

1. While *currentNode* has a parent node within the [flat tree](#):
  1. If *currentNode* is slotted into the second slot of a `details`<sup>p637</sup> element:
    1. Set *currentNode* to the `details`<sup>p637</sup> element which *currentNode* is slotted into.
    2. If the `open`<sup>p638</sup> attribute is not set on *currentNode*, then [set](#) the `open`<sup>p638</sup> attribute on *currentNode* to the empty string.
  2. Otherwise, set *currentNode* to the parent node of *currentNode* within the [flat tree](#).

#### Example

The following example shows the `details`<sup>p637</sup> element being used to hide technical details in a progress report.

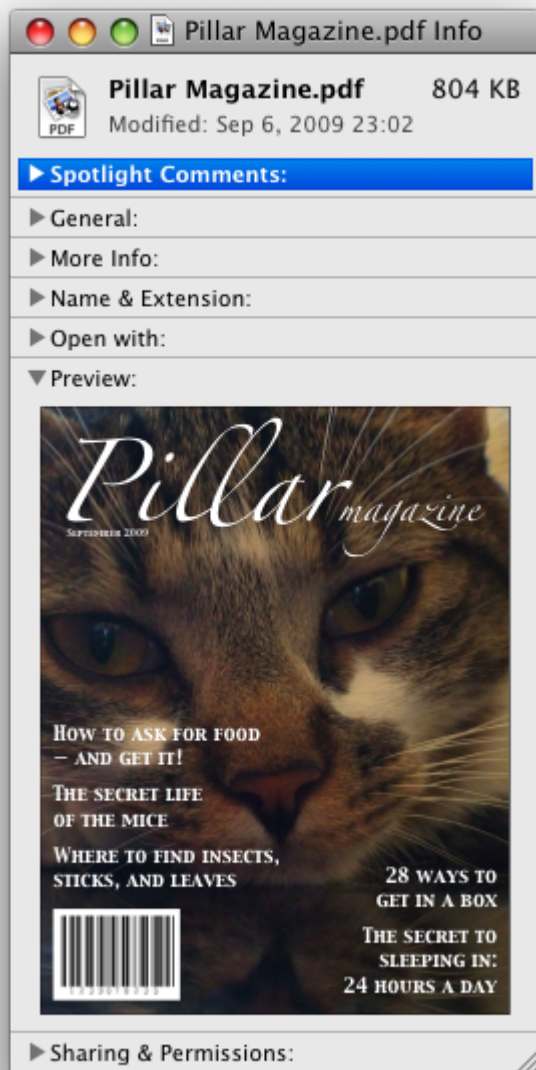

```
<section class="progress window">
  <h1>Copying "Really Achieving Your Childhood Dreams"</h1>
  <details>
    <summary>Copying... <progress max="375505392" value="97543282"></progress> 25%</summary>
    <dl>
      <dt>Transfer rate:</dt> <dd>452KB/s</dd>
      <dt>Local filename:</dt> <dd>/home/rpausch/raycd.m4v</dd>
      <dt>Remote filename:</dt> <dd>/var/www/lectures/raycd.m4v</dd>
      <dt>Duration:</dt> <dd>01:16:27</dd>
      <dt>Color profile:</dt> <dd>SD (6-1-6)</dd>
      <dt>Dimensions:</dt> <dd>320x240</dd>
    </dl>
  </details>
</section>
```

#### Example

The following shows how a `details`<sup>p637</sup> element can be used to hide some controls by default:

```
<details>
  <summary><label for=fn>Name & Extension:</label></summary>
  <p><input type=text id=fn name=fn value="Pillar Magazine.pdf">
  <p><label><input type=checkbox name=ext checked> Hide extension</label>
</details>
```

One could use this in conjunction with other `details`<sup>p637</sup> in a list to allow the user to collapse a set of fields down to a small set of headings, with the ability to open each one.

In these examples, the summary really just summarizes what the controls can change, and not the actual values, which is less than ideal.

#### Example

The following example shows the `name`<sup>p638</sup> attribute of the `details`<sup>p637</sup> element being used to create an exclusive accordion, a set of `details`<sup>p637</sup> elements where a user action to open one `details`<sup>p637</sup> element causes any open `details`<sup>p637</sup> to close.

```
<section class="characteristics">
  <details name="frame-characteristics">
    <summary>Material</summary>
    The picture frame is made of solid oak wood.
  </details>
  <details name="frame-characteristics">
    <summary>Size</summary>
    The picture frame fits a photo 40cm tall and 30cm wide.
  </details>
</section>
```

```

    The frame is 45cm tall, 35cm wide, and 2cm thick.
  </details>
  <details name="frame-characteristics">
    <summary>Color</summary>
    The picture frame is available in its natural wood
    color, or with black stain.
  </details>
</section>

```

### Example

The following example shows what happens when the `open`<sup>p638</sup> attribute is set on a `details`<sup>p637</sup> element that is part of a set of elements using the `name`<sup>p638</sup> attribute to create an exclusive accordion.

Given the initial markup:

```

<section class="characteristics">
  <details name="frame-characteristics" id="d1" open>...</details>
  <details name="frame-characteristics" id="d2">...</details>
  <details name="frame-characteristics" id="d3">...</details>
</section>

```

and the script:

```
document.getElementById("d2").setAttribute("open", "");
```

then the resulting tree after the script executes will be equivalent to the markup:

```

<section class="characteristics">
  <details name="frame-characteristics" id="d1">...</details>
  <details name="frame-characteristics" id="d2" open>...</details>
  <details name="frame-characteristics" id="d3">...</details>
</section>

```

because setting the `open`<sup>p638</sup> attribute on d2 removes it from d1.

The same happens when the user activates the `summary`<sup>p643</sup> element inside of d2.

### Example

Because the `open`<sup>p638</sup> attribute is added and removed automatically as the user interacts with the control, it can be used in CSS to style the element differently based on its state. Here, a style sheet is used to animate the color of the summary when the element is opened or closed:

```

<style>
  details > summary { transition: color 1s; color: black; }
  details[open] > summary { color: red; }
</style>
<details>
  <summary>Automated Status: Operational</summary>
  <p>Velocity: 12m/s</p>
  <p>Direction: North</p>
</details>

```

## 4.11.2 The **summary** element § p64

3

### Categories<sup>p146</sup>:

None.

### Contexts in which this element can be used<sup>p146</sup>:

As the [first child](#) of a [details](#)<sup>p637</sup> element.

### Content model<sup>p146</sup>:

[Phrasing content](#)<sup>p150</sup>, optionally intermixed with [heading content](#)<sup>p149</sup>.

### Tag omission in text/html<sup>p146</sup>:

Neither tag is omissible.

### Content attributes<sup>p146</sup>:

[Global attributes](#)<sup>p154</sup>

### Accessibility considerations<sup>p146</sup>:

[For authors](#).

[For implementers](#).

### DOM interface<sup>p147</sup>:

Uses [HTMLElement](#)<sup>p142</sup>.

The [summary](#)<sup>p643</sup> element [represents](#)<sup>p141</sup> a summary, caption, or legend for the rest of the contents of the [summary](#)<sup>p643</sup> element's parent [details](#)<sup>p637</sup> element, if any.

A [summary](#)<sup>p643</sup> element is a **summary for its parent details** if the following algorithm returns true:

1. If this [summary](#)<sup>p643</sup> element has no parent, then return false.
2. Let *parent* be this [summary](#)<sup>p643</sup> element's parent.
3. If *parent* is not a [details](#)<sup>p637</sup> element, then return false.
4. If *parent*'s first [summary](#)<sup>p643</sup> element child is not this [summary](#)<sup>p643</sup> element, then return false.
5. Return true.

The [activation behavior](#) of [summary](#)<sup>p643</sup> elements is to run the following steps:

1. If this [summary](#)<sup>p643</sup> element is not the [summary for its parent details](#)<sup>p643</sup>, then return.
2. Let *parent* be this [summary](#)<sup>p643</sup> element's parent.
3. If the [open](#)<sup>p638</sup> attribute is present on *parent*, then [remove](#) it. Otherwise, [set](#) *parent*'s [open](#)<sup>p638</sup> attribute to the empty string.

#### Note

*This will then run the [details notification task steps](#)<sup>p639</sup>.*

## 4.11.3 Commands § p64

3

### 4.11.3.1 Facets § p64

3

A **command** is the abstraction behind menu items, buttons, and links. Once a command is defined, other parts of the interface can refer to the same command, allowing many access points to a single feature to share facets such as the [Disabled State](#)<sup>p644</sup>.

Commands are defined to have the following **facets**:

#### Label

The name of the command as seen by the user.

#### Access Key

A key combination selected by the user agent that triggers the command. A command might not have an Access Key.

### Hidden State

Whether the command is hidden or not (basically, whether it should be shown in menus).

### Disabled State

Whether the command is relevant and can be triggered or not.

### Action

The actual effect that triggering the command will have. This could be a scripted event handler, a [URL](#) to which to [navigate](#)<sup>p1014</sup>, or a form submission.

User agents may expose the [commands](#)<sup>p643</sup> that match the following criteria:

- The [Hidden State](#)<sup>p644</sup> facet is false (visible)
- The element is [in a document](#) with a non-null [browsing context](#)<sup>p999</sup>.
- Neither the element nor any of its ancestors has a [hidden](#)<sup>p824</sup> attribute specified.

User agents are encouraged to do this especially for commands that have [Access Keys](#)<sup>p643</sup>, as a way to advertise those keys to the user.

### Example

For example, such commands could be listed in the user agent's menu bar.

#### 4.11.3.2 Using the **a** element to define a command § p64 4

An [a](#)<sup>p257</sup> element with an [href](#)<sup>p303</sup> attribute [defines a command](#)<sup>p643</sup>.

The [Label](#)<sup>p643</sup> of the command is the element's [descendant text content](#).

The [Access Key](#)<sup>p643</sup> of the command is the element's [assigned access key](#)<sup>p852</sup>, if any.

The [Hidden State](#)<sup>p644</sup> of the command is true (hidden) if the element has a [hidden](#)<sup>p824</sup> attribute, and false otherwise.

The [Disabled State](#)<sup>p644</sup> facet of the command is true if the element or one of its ancestors is [inert](#)<sup>p827</sup>, and false otherwise.

The [Action](#)<sup>p644</sup> of the command is to [fire a click event](#)<sup>p1148</sup> at the element.

#### 4.11.3.3 Using the **button** element to define a command § p64 4

A [button](#)<sup>p566</sup> element always [defines a command](#)<sup>p643</sup>.

The [Label](#)<sup>p643</sup>, [Access Key](#)<sup>p643</sup>, [Hidden State](#)<sup>p644</sup>, and [Action](#)<sup>p644</sup> facets of the command are determined [as for a elements](#)<sup>p644</sup> (see the previous section).

The [Disabled State](#)<sup>p644</sup> of the command is true if the element or one of its ancestors is [inert](#)<sup>p827</sup>, or if the element's [disabled](#)<sup>p601</sup> state is set, and false otherwise.

#### 4.11.3.4 Using the **input** element to define a command § p64 4

An [input](#)<sup>p520</sup> element whose [type](#)<sup>p523</sup> attribute is in one of the [Submit Button](#)<sup>p546</sup>, [Reset Button](#)<sup>p549</sup>, [Image Button](#)<sup>p547</sup>, [Button](#)<sup>p550</sup>, [Radio Button](#)<sup>p543</sup>, or [Checkbox](#)<sup>p542</sup> states [defines a command](#)<sup>p643</sup>.

The [Label](#)<sup>p643</sup> of the command is determined as follows:

- If the [type](#)<sup>p523</sup> attribute is in one of the [Submit Button](#)<sup>p546</sup>, [Reset Button](#)<sup>p549</sup>, [Image Button](#)<sup>p547</sup>, or [Button](#)<sup>p550</sup> states, then the [Label](#)<sup>p643</sup> is the string given by the [value](#)<sup>p525</sup> attribute, if any, and a UA-dependent, locale-dependent value that the UA uses to label the button itself if the attribute is absent.

- Otherwise, if the element is a [labeled control](#)<sup>p518</sup>, then the [Label](#)<sup>p643</sup> is the [descendant text content](#) of the first [label](#)<sup>p518</sup> element in [tree order](#) whose [labeled control](#)<sup>p518</sup> is the element in question. (In JavaScript terms, this is given by `element.labels[0].textContent`.)
- Otherwise, if the [value](#)<sup>p525</sup> attribute is present, then the [Label](#)<sup>p643</sup> is the value of that attribute.
- Otherwise, the [Label](#)<sup>p643</sup> is the empty string.

#### Note

Even though the [value](#)<sup>p525</sup> attribute on [input](#)<sup>p520</sup> elements in the [Image Button](#)<sup>p547</sup> state is non-conformant, the attribute can still contribute to the [Label](#)<sup>p643</sup> determination, if it is present and the Image Button's [alt](#)<sup>p548</sup> attribute is missing.

The [Access Key](#)<sup>p643</sup> of the command is the element's [assigned access key](#)<sup>p852</sup>, if any.

The [Hidden State](#)<sup>p644</sup> of the command is true (hidden) if the element has a [hidden](#)<sup>p824</sup> attribute, and false otherwise.

The [Disabled State](#)<sup>p644</sup> of the command is true if the element or one of its ancestors is [inert](#)<sup>p827</sup>, or if the element's [disabled](#)<sup>p601</sup> state is set, and false otherwise.

The [Action](#)<sup>p644</sup> of the command is to [fire a click event](#)<sup>p1148</sup> at the element.

#### 4.11.3.5 Using the **option** element to define a command § p64 5

An [option](#)<sup>p577</sup> element with an ancestor [select](#)<sup>p568</sup> element and either no [value](#)<sup>p578</sup> attribute or a [value](#)<sup>p578</sup> attribute that is not the empty string [defines a command](#)<sup>p643</sup>.

The [Label](#)<sup>p643</sup> of the command is the value of the [option](#)<sup>p577</sup> element's [label](#)<sup>p578</sup> attribute, if there is one, or else the [option](#)<sup>p577</sup> element's [descendant text content](#), with [ASCII whitespace stripped and collapsed](#).

The [Access Key](#)<sup>p643</sup> of the command is the element's [assigned access key](#)<sup>p852</sup>, if any.

The [Hidden State](#)<sup>p644</sup> of the command is true (hidden) if the element has a [hidden](#)<sup>p824</sup> attribute, and false otherwise.

The [Disabled State](#)<sup>p644</sup> of the command is true if the element is [disabled](#)<sup>p578</sup>, or if its nearest ancestor [select](#)<sup>p568</sup> element is [disabled](#)<sup>p601</sup>, or if it or one of its ancestors is [inert](#)<sup>p827</sup>, and false otherwise.

If the [option](#)<sup>p577</sup>'s nearest ancestor [select](#)<sup>p568</sup> element has a [multiple](#)<sup>p569</sup> attribute, the [Action](#)<sup>p644</sup> of the command is to [toggle](#)<sup>p571</sup> the [option](#)<sup>p577</sup> element. Otherwise, the [Action](#)<sup>p644</sup> is to [pick](#)<sup>p570</sup> the [option](#)<sup>p577</sup> element.

#### 4.11.3.6 Using the **accesskey** attribute on a **legend** element to define a command § p64 5

A [legend](#)<sup>p596</sup> element [defines a command](#)<sup>p643</sup> if all of the following are true:

- It has an [assigned access key](#)<sup>p852</sup>.
- It is a child of a [fieldset](#)<sup>p594</sup> element.
- Its parent has a descendant that [defines a command](#)<sup>p643</sup> that is neither a [label](#)<sup>p518</sup> element nor a [legend](#)<sup>p596</sup> element. This element, if it exists, is **the legend element's accesskey delegatee**.

The [Label](#)<sup>p643</sup> of the command is the element's [descendant text content](#).

The [Access Key](#)<sup>p643</sup> of the command is the element's [assigned access key](#)<sup>p852</sup>.

The [Hidden State](#)<sup>p644</sup>, [Disabled State](#)<sup>p644</sup>, and [Action](#)<sup>p644</sup> facets of the command are the same as the respective facets of [the legend element's accesskey delegatee](#)<sup>p645</sup>.

#### Example

In this example, the [legend](#)<sup>p596</sup> element specifies an [accesskey](#)<sup>p851</sup>, which, when activated, will delegate to the [input](#)<sup>p520</sup> element

inside the [legend<sup>p596</sup>](#) element.

```
<fieldset>
  <legend accesskey=p>
    <label>I want <input name=pizza type=number step=1 value=1 min=0>
      pizza(s) with these toppings</label>
  </legend>
  <label><input name=pizza-cheese type=checkbox checked> Cheese</label>
  <label><input name=pizza-ham type=checkbox checked> Ham</label>
  <label><input name=pizza-pineapple type=checkbox> Pineapple</label>
</fieldset>
```

#### 4.11.3.7 Using the [accesskey](#) attribute to define a command on other elements §<sup>p64</sup><sub>6</sub>

An element that has an [assigned access key<sup>p852</sup>](#) [defines a command<sup>p643</sup>](#).

If one of the earlier sections that define elements that [define commands<sup>p643</sup>](#) define that this element [defines a command<sup>p643</sup>](#), then that section applies to this element, and this section does not. Otherwise, this section applies to that element.

The [Label<sup>p643</sup>](#) of the command depends on the element. If the element is a [labeled control<sup>p518</sup>](#), the [descendant text content](#) of the first [Label<sup>p518</sup>](#) element in [tree order](#) whose [labeled control<sup>p518</sup>](#) is the element in question is the [Label<sup>p643</sup>](#) (in JavaScript terms, this is given by `element.labels[0].textContent`). Otherwise, the [Label<sup>p643</sup>](#) is the element's [descendant text content](#).

The [Access Key<sup>p643</sup>](#) of the command is the element's [assigned access key<sup>p852</sup>](#).

The [Hidden State<sup>p644</sup>](#) of the command is true (hidden) if the element has a [hidden<sup>p824</sup>](#) attribute, and false otherwise.

The [Disabled State<sup>p644</sup>](#) of the command is true if the element or one of its ancestors is [inert<sup>p827</sup>](#), and false otherwise.

The [Action<sup>p644</sup>](#) of the command is to run the following steps:

1. Run the [focusing steps<sup>p842</sup>](#) for the element.
2. [Fire a click event<sup>p1148</sup>](#) at the element.

#### 4.11.4 The [dialog](#) element §<sup>p64</sup><sub>6</sub>

✓ MDN

##### Categories<sup>p146</sup>:

[Flow content<sup>p149</sup>](#).

##### Contexts in which this element can be used<sup>p146</sup>:

Where [flow content<sup>p149</sup>](#) is expected.

##### Content model<sup>p146</sup>:

[Flow content<sup>p149</sup>](#).

##### Tag omission in text/html<sup>p146</sup>:

Neither tag is omissible.

##### Content attributes<sup>p146</sup>:

[Global attributes<sup>p154</sup>](#)

[open<sup>p648</sup>](#) — Whether the dialog box is showing

##### Accessibility considerations<sup>p146</sup>:

[For authors.](#)

[For implementers.](#)

✓ MDN

## DOM interface<sup>p147</sup>:

```
IDL [Exposed=Window]
interface HTMLDialogElement : HTMLElement {
    [HTMLConstructor] constructor();

    [CEReactions] attribute boolean open;
    attribute DOMString returnValue;
    [CEReactions] undefined show();
    [CEReactions] undefined showModal();
    [CEReactions] undefined close(optional DOMString returnValue);
};
```

The [dialog<sup>p646</sup>](#) element represents a transitory part of an application, in the form of a small window ("dialog box"), which the user interacts with to perform a task or gather information. Once the user is done, the dialog can be automatically closed by the application, or manually closed by the user.

Especially for modal dialogs, which are a familiar pattern across all types of applications, authors should work to ensure that dialogs in their web applications behave in a way that is familiar to users of non-web applications.

### Note

*As with all HTML elements, it is not conforming to use the [dialog<sup>p646</sup>](#) element when attempting to represent another type of control. For example, context menus, tooltips, and popup listboxes are not dialog boxes, so abusing the [dialog<sup>p646</sup>](#) element to implement these patterns is incorrect.*

An important part of user-facing dialog behavior is the placement of initial focus. The [dialog focusing steps<sup>p650</sup>](#) attempt to pick a good candidate for initial focus when a dialog is shown, but might not be a substitute for authors carefully thinking through the correct choice to match user expectations for a specific dialog. As such, authors should use the [autofocus<sup>p848</sup>](#) attribute on the descendant element of the dialog that the user is expected to immediately interact with after the dialog opens. If there is no such element, then authors should use the [autofocus<sup>p848</sup>](#) attribute on the [dialog<sup>p646</sup>](#) element itself.

### Example

In the following example, a dialog is used for editing the details of a product in an inventory management web application.

```
<dialog>
  <label>Product Number <input type="text" readonly></label>
  <label>Product Name <input type="text" autofocus></label>
</dialog>
```

If the [autofocus<sup>p848</sup>](#) attribute was not present, the Product Number field would have been focused by the dialog focusing steps. Although that is reasonable behavior, the author determined that the more relevant field to focus was the Product Name field, as the Product Number field is readonly and expects no user input. So, the author used autofocus to override the default.

Even if the author wants to focus the Product Number field by default, they are best off explicitly specifying that by using autofocus on that [input<sup>p529</sup>](#) element. This makes the intent obvious to future readers of the code, and ensures the code stays robust in the face of future updates. (For example, if another developer added a close button, and positioned it in the node tree before the Product Number field).

Another important aspect of user behavior is whether dialogs are scrollable or not. In some cases, overflow (and thus scrollability) cannot be avoided, e.g., when it is caused by the user's high text zoom settings. But in general, scrollable dialogs are not expected by users. Adding large text nodes directly to dialog elements is particularly bad as this is likely to cause the dialog element itself to overflow. Authors are best off avoiding them.

### Example

The following terms of service dialog respects the above suggestions.

```
<dialog style="height: 80vh;">
  <div style="overflow: auto; height: 60vh;" autofocus>
    <p>By placing an order via this Web site on the first day of the fourth month of the year
```

```

2010 Anno Domini, you agree to grant Us a non-transferable option to claim, for now and for
ever more, your immortal soul.</p>
<p>Should We wish to exercise this option, you agree to surrender your immortal soul,
and any claim you may have on it, within 5 (five) working days of receiving written
notification from this site or one of its duly authorized minions.</p>
<!-- ... etc., with many more <p> elements ... -->
</div>
<form method="dialog">
  <button type="submit" value="agree">Agree</button>
  <button type="submit" value="disagree">Disagree</button>
</form>
</dialog>

```

Note how the [dialog focusing steps](#)<sup>p650</sup> would have picked the scrollable [div](#)<sup>p256</sup> element by default, but similarly to the previous example, we have placed [autofocus](#)<sup>p848</sup> on the [div](#)<sup>p256</sup> so as to be more explicit and robust against future changes.

In contrast, if the [p](#)<sup>p229</sup> elements expressing the terms of service did not have such a wrapper [div](#)<sup>p256</sup> element, then the [dialog](#)<sup>p646</sup> itself would become scrollable, violating the above advice. Furthermore, in the absence of any [autofocus](#)<sup>p848</sup> attribute, such a markup pattern would have violated the above advice and tripped up the [dialog focusing steps](#)<sup>p650</sup>'s default behavior, and caused focus to jump to the Agree [button](#)<sup>p566</sup>, which is a bad user experience.

The [open](#) attribute is a [boolean attribute](#)<sup>p75</sup>. When specified, it indicates that the [dialog](#)<sup>p646</sup> element is active and that the user can interact with it.

A [dialog](#)<sup>p646</sup> element without an [open](#)<sup>p648</sup> attribute specified should not be shown to the user. This requirement may be implemented indirectly through the style layer. For example, user agents that [support the suggested default rendering](#)<sup>p48</sup> implement this requirement using the CSS rules described in the [Rendering section](#)<sup>p1388</sup>.

#### Note

Removing the [open](#)<sup>p648</sup> attribute will usually hide the dialog. However, doing so has a number of strange additional consequences:

- The [close](#)<sup>p1471</sup> event will not be fired.
- The [close\(\)](#)<sup>p650</sup> method, and any [close requests](#)<sup>p863</sup>, will no longer be able to close the dialog.
- If the dialog was shown using its [showModal\(\)](#)<sup>p649</sup> method, the [Document](#)<sup>p130</sup> will still be [blocked](#)<sup>p828</sup>.

For these reasons, it is generally better to never remove the [open](#)<sup>p648</sup> attribute manually. Instead, use the [close\(\)](#)<sup>p650</sup> method to close the dialog, or the [hidden](#)<sup>p824</sup> attribute to hide it.

The [tabindex](#)<sup>p838</sup> attribute must not be specified on [dialog](#)<sup>p646</sup> elements.

#### For web developers (non-normative)

**[dialog.show](#)<sup>p649</sup>()**

Displays the [dialog](#)<sup>p646</sup> element.

**[dialog.showModal](#)<sup>p649</sup>()**

Displays the [dialog](#)<sup>p646</sup> element and makes it the top-most modal dialog.

This method honors the [autofocus](#)<sup>p848</sup> attribute.

**[dialog.close](#)<sup>p650</sup>([ *result* ])**

Closes the [dialog](#)<sup>p646</sup> element.

The argument, if provided, provides a return value.

**[dialog.returnValue](#)<sup>p651</sup> [ = *result* ]**

Returns the [dialog](#)<sup>p646</sup>'s return value.

Can be set, to update the return value.

Every [dialog](#)<sup>p646</sup> element has a **dialog toggle task tracker**, which is a [toggle task tracker](#)<sup>p833</sup> or null, initially null.

To **queue a dialog toggle event task** given a [dialog](#)<sup>p646</sup> element *element*, a string *oldState*, and a string *newState*:

1. If *element*'s [dialog toggle task tracker](#)<sup>p648</sup> is not null, then:
  1. Set *oldState* to *element*'s [dialog toggle task tracker](#)<sup>p648</sup>'s [old state](#)<sup>p833</sup>.
  2. Remove *element*'s [dialog toggle task tracker](#)<sup>p648</sup>'s [task](#)<sup>p833</sup> from its [task queue](#)<sup>p1123</sup>.
  3. Set *element*'s [dialog toggle task tracker](#)<sup>p648</sup> to null.
2. [Queue an element task](#)<sup>p1125</sup> given the [DOM manipulation task source](#)<sup>p1134</sup> and *element* to run the following steps:
  1. [Fire an event](#) named [toggle](#)<sup>p1472</sup> at *element*, using [ToggleEvent](#)<sup>p833</sup>, with the [oldState](#)<sup>p833</sup> attribute initialized to *oldState* and the [newState](#)<sup>p833</sup> attribute initialized to *newState*.
  2. Set *element*'s [dialog toggle task tracker](#)<sup>p648</sup> to null.
3. Set *element*'s [dialog toggle task tracker](#)<sup>p648</sup> to a struct with [task](#)<sup>p833</sup> set to the just-queued [task](#)<sup>p1124</sup> and [old state](#)<sup>p833</sup> set to *oldState*.

The **show()** method steps are:

1. If *this* has an [open](#)<sup>p648</sup> attribute and the [is modal](#)<sup>p652</sup> flag of *this* is false, then return.
2. If *this* has an [open](#)<sup>p648</sup> attribute, then throw an ["InvalidStateError" DOMException](#).
3. If the result of [firing an event](#) named [beforetoggle](#)<sup>p1471</sup>, using [ToggleEvent](#)<sup>p833</sup>, with the [cancelable](#) attribute initialized to true, the [oldState](#)<sup>p833</sup> attribute initialized to "closed", and the [newState](#)<sup>p833</sup> attribute initialized to "open" at *this* is false, then return.
4. If *this* has an [open](#)<sup>p648</sup> attribute, then return.
5. [Queue a dialog toggle event task](#)<sup>p649</sup> given *subject*, "closed", and "open".
6. Add an [open](#)<sup>p648</sup> attribute to *this*, whose value is the empty string.
7. Set *this*'s [previously focused element](#)<sup>p652</sup> to the [focused](#)<sup>p836</sup> element.
8. Let *hideUntil* be the result of running [topmost popover ancestor](#)<sup>p892</sup> given *this*, null, and false.
9. If *hideUntil* is null, then set *hideUntil* to *this*'s [node document](#).
10. Run [hide all popovers until](#)<sup>p891</sup> given *hideUntil*, false, and true.
11. Run the [dialog focusing steps](#)<sup>p650</sup> given *this*.

The **showModal()** method steps are:

1. If *this* has an [open](#)<sup>p648</sup> attribute and the [is modal](#)<sup>p652</sup> flag of *this* is true, then return.
2. If *this* has an [open](#)<sup>p648</sup> attribute, then throw an ["InvalidStateError" DOMException](#).
3. If *this*'s [node document](#) is not [fully active](#)<sup>p1003</sup>, then throw an ["InvalidStateError" DOMException](#).
4. If *this* is not [connected](#), then throw an ["InvalidStateError" DOMException](#).
5. If *this* is in the [popover showing state](#)<sup>p887</sup>, then throw an ["InvalidStateError" DOMException](#).
6. If the result of [firing an event](#) named [beforetoggle](#)<sup>p1471</sup>, using [ToggleEvent](#)<sup>p833</sup>, with the [cancelable](#) attribute initialized to true, the [oldState](#)<sup>p833</sup> attribute initialized to "closed", and the [newState](#)<sup>p833</sup> attribute initialized to "open" at *this* is false, then return.
7. If *this* has an [open](#)<sup>p648</sup> attribute, then return.
8. If *this* is not [connected](#), then return.
9. If *this* is in the [popover showing state](#)<sup>p887</sup>, then return.
10. [Queue a dialog toggle event task](#)<sup>p649</sup> given *subject*, "closed", and "open".
11. Add an [open](#)<sup>p648</sup> attribute to *this*, whose value is the empty string.

12. Set the `is_modal`<sup>p652</sup> flag of `this` to true.
13. Let `this`'s `node document` be `blocked by the modal dialog`<sup>p828</sup> `this`.

**Note**

*This will cause the `focused area of the document`<sup>p836</sup> to become `inert`<sup>p827</sup> (unless that currently focused area is a `shadow-including descendant` of subject). In such cases, the `focused area of the document`<sup>p836</sup> will soon be `reset`<sup>p1130</sup> to the `viewport`. In a couple steps we will attempt to find a better candidate to focus.*

14. If `this`'s `node document`'s `top layer` does not already `contain this`, then `add an element to the top layer` given `this`.
15. Set `this`'s `close watcher`<sup>p651</sup> to the result of `establishing a close watcher`<sup>p865</sup> given `this`'s `relevant global object`<sup>p1083</sup>, with:
  - `cancelAction`<sup>p865</sup> given `canPreventClose` being to return the result of `firing an event` named `cancel`<sup>p1471</sup> at `this`, with the `cancelable` attribute initialized to `canPreventClose`.
  - `closeAction`<sup>p865</sup> being to `close the dialog`<sup>p651</sup> given `this` and null.
16. Set `this`'s `previously focused element`<sup>p652</sup> to the `focused`<sup>p836</sup> element.
17. Let `hideUntil` be the result of running `topmost popover ancestor`<sup>p892</sup> given `this`, null, and false.
18. If `hideUntil` is null, then set `hideUntil` to `this`'s `node document`.
19. Run `hide all popovers until`<sup>p891</sup> given `hideUntil`, false, and true.
20. Run the `dialog focusing steps`<sup>p650</sup> given `this`.

The **dialog focusing steps**, given a `dialog`<sup>p646</sup> element *subject*, are as follows:

1. Let *control* be null.
2. If *subject* has the `autofocus`<sup>p848</sup> attribute, then set *control* to *subject*.
3. If *control* is null, then set *control* to the `focus delegate`<sup>p841</sup> of *subject*.
4. If *control* is null, then set *control* to *subject*.
5. Run the `focusing steps`<sup>p842</sup> for *control*.

**Note**

*If *control* is not `focusable`<sup>p837</sup>, this will do nothing. This would only happen if *subject* had no focus delegate, and the user agent decided that `dialog`<sup>p646</sup> elements were not generally focusable. In that case, any `earlier modifications`<sup>p650</sup> to the `focused area of the document`<sup>p836</sup> will apply.*

6. Let *topDocument* be *control*'s `node navigable`<sup>p989</sup>'s `top-level traversable`<sup>p990</sup>'s `active document`<sup>p989</sup>.
7. If *control*'s `node document`'s `origin` is not the `same`<sup>p899</sup> as the `origin` of *topDocument*, then return.
8. `Empty` *topDocument*'s `autofocus candidates`<sup>p848</sup>.
9. Set *topDocument*'s `autofocus processed flag`<sup>p848</sup> to true.

The `dialog`<sup>p646</sup> **HTML element removing steps**<sup>p45</sup>, given *removedNode* and *oldParent*, are:

1. If *removedNode*'s `close watcher`<sup>p651</sup> is not null, then:
  1. `Destroy`<sup>p866</sup> *removedNode*'s `close watcher`<sup>p651</sup>.
  2. Set *removedNode*'s `close watcher`<sup>p651</sup> to null.
2. If *removedNode*'s `node document`'s `top layer contains` *removedNode*, then `remove an element from the top layer immediately` given *removedNode*.
3. Set the `is_modal`<sup>p652</sup> flag of *removedNode* to false.

The **`close(returnValue)`** method steps are:

1. If *returnValue* is not given, then set it to null.

2. [Close the dialog](#)<sup>p651</sup> [this](#) with `returnValue`.

When a [dialog](#)<sup>p646</sup> element *subject* is to be **closed**, with null or a string *result*, run these steps:

1. If *subject* does not have an [open](#)<sup>p648</sup> attribute, then return.
2. [Fire an event](#) named [beforetoggle](#)<sup>p1471</sup>, using [ToggleEvent](#)<sup>p833</sup>, with the [oldState](#)<sup>p833</sup> attribute initialized to "open" and the [newState](#)<sup>p833</sup> attribute initialized to "closed" at *subject*.
3. If *subject* does not have an [open](#)<sup>p648</sup> attribute, then return.
4. [Queue a dialog toggle event task](#)<sup>p649</sup> given *subject*, "open", and "closed".
5. Remove *subject*'s [open](#)<sup>p648</sup> attribute.
6. If the [is modal](#)<sup>p652</sup> flag of *subject* is true, then [request an element to be removed from the top layer](#) given *subject*.
7. Let *wasModal* be the value of *subject*'s [is modal](#)<sup>p652</sup> flag.
8. Set the [is modal](#)<sup>p652</sup> flag of *subject* to false.
9. If *result* is not null, then set the [returnValue](#)<sup>p651</sup> attribute to *result*.
10. If *subject*'s [previously focused element](#)<sup>p652</sup> is not null, then:
  1. Let *element* be *subject*'s [previously focused element](#)<sup>p652</sup>.
  2. Set *subject*'s [previously focused element](#)<sup>p652</sup> to null.
  3. If *subject*'s [node document](#)'s [focused area of the document](#)<sup>p836</sup>'s [DOM anchor](#)<sup>p835</sup> is a [shadow-including inclusive descendant](#) of *element*, or *wasModal* is true, then run the [focusing steps](#)<sup>p842</sup> for *element*; the viewport should not be scrolled by doing this step.
11. [Queue an element task](#)<sup>p1125</sup> on the [user interaction task source](#)<sup>p1134</sup> given the *subject* element to [fire an event](#) named [close](#)<sup>p1471</sup> at *subject*.
12. If *subject*'s [close watcher](#)<sup>p651</sup> is not null, then:
  1. [Destroy](#)<sup>p866</sup> *subject*'s [close watcher](#)<sup>p651</sup>.
  2. Set *subject*'s [close watcher](#)<sup>p651</sup> to null.

The [returnValue](#) IDL attribute, on getting, must return the last value to which it was set. On setting, it must be set to the new value. When the element is created, it must be set to the empty string.

#### Note

We use *show/close* as the verbs for [dialog](#)<sup>p646</sup> elements, as opposed to verb pairs that are more commonly thought of as antonyms such as *show/hide* or *open/close*, due to the following constraints:

- Hiding a dialog is different from closing one. Closing a dialog gives it a return value, fires an event, unblocks the page for other dialogs, and so on. Whereas hiding a dialog is a purely visual property, and is something you can already do with the [hidden](#)<sup>p824</sup> attribute or by removing the [open](#)<sup>p648</sup> attribute. (See also the [note above](#)<sup>p648</sup> about removing the [open](#)<sup>p648</sup> attribute, and how hiding the dialog in that way is generally not desired.)
- Showing a dialog is different from opening one. Opening a dialog consists of creating and showing that dialog (similar to how [window.open\(\)](#)<sup>p926</sup> both creates and shows a new window). Whereas showing the dialog is the process of taking a [dialog](#)<sup>p646</sup> element that is already in the DOM, and making it interactive and visible to the user.
- If we were to have a `dialog.open()` method despite the above, it would conflict with the [dialog.open](#)<sup>p652</sup> property.

Furthermore, a [survey](#) of many other UI frameworks contemporary to the original design of the [dialog](#)<sup>p646</sup> element made it clear that the *show/close* verb pair was reasonably common.

In summary, it turns out that the implications of certain verbs, and how they are used in technology contexts, mean that paired actions such as showing and closing a dialog are not always expressible as antonyms.

Each [dialog](#)<sup>p646</sup> element has a **close watcher**, which is a [close watcher](#)<sup>p865</sup> or null, initially null.

Each [dialog](#)<sup>p646</sup> element has an **is modal** flag. When a [dialog](#)<sup>p646</sup> element is created, this flag must be set to false.

Each [HTML element](#)<sup>p45</sup> has a **previously focused element** which is null or an element, and it is initially null. When [showModal\(\)](#)<sup>p649</sup> and [show\(\)](#)<sup>p649</sup> are called, this element is set to the currently [focused](#)<sup>p836</sup> element before running the [dialog focusing steps](#)<sup>p650</sup>. Elements with the [popover](#)<sup>p886</sup> attribute set this element to the currently [focused](#)<sup>p836</sup> element during the [show popover algorithm](#)<sup>p888</sup>.

The **open** IDL attribute must [reflect](#)<sup>p104</sup> the [open](#)<sup>p648</sup> content attribute.

#### Example

This dialog box has some small print. The [strong](#)<sup>p261</sup> element is used to draw the user's attention to the more important part.

```
<dialog>
  <h1>Add to Wallet</h1>
  <p><strong><label for=amt>How many gold coins do you want to add to your
wallet?</label></strong></p>
  <p><input id=amt name=amt type=number min=0 step=0.01 value=100></p>
  <p><small>You add coins at your own risk.</small></p>
  <p><label><input name=round type=checkbox> Only add perfectly round coins</label></p>
  <p><input type=button onclick="submit()" value="Add Coins"></p>
</dialog>
```

## 4.12 Scripting §<sup>p65</sup><sub>2</sub>

Scripts allow authors to add interactivity to their documents.

Authors are encouraged to use declarative alternatives to scripting where possible, as declarative mechanisms are often more maintainable, and many users disable scripting.

#### Example

For example, instead of using a script to show or hide a section to show more details, the [details](#)<sup>p637</sup> element could be used.

Authors are also encouraged to make their applications degrade gracefully in the absence of scripting support.

#### Example

For example, if an author provides a link in a table header to dynamically resort the table, the link could also be made to function without scripts by requesting the sorted table from the server.

### 4.12.1 The [script](#) element §<sup>p65</sup><sub>2</sub>

#### Categories<sup>p146</sup>:

[Metadata content](#)<sup>p148</sup>.  
[Flow content](#)<sup>p149</sup>.  
[Phrasing content](#)<sup>p150</sup>.  
[Script-supporting element](#)<sup>p151</sup>.

#### Contexts in which this element can be used<sup>p146</sup>:

Where [metadata content](#)<sup>p148</sup> is expected.  
Where [phrasing content](#)<sup>p150</sup> is expected.  
Where [script-supporting elements](#)<sup>p151</sup> are expected.

#### Content model<sup>p146</sup>:

If there is no [src](#)<sup>p654</sup> attribute, depends on the value of the [type](#)<sup>p653</sup> attribute, but must match [script content restrictions](#)<sup>p666</sup>.  
If there is a [src](#)<sup>p654</sup> attribute, the element must be either empty or contain only [script documentation](#)<sup>p668</sup> that also matches [script content restrictions](#)<sup>p666</sup>.

## Tag omission in text/html<sup>p146</sup>:

Neither tag is omissible.

## Content attributes<sup>p146</sup>:

[Global attributes](#)<sup>p154</sup>

[src](#)<sup>p654</sup> — Address of the resource

[type](#)<sup>p653</sup> — Type of script

[nomodule](#)<sup>p654</sup> — Prevents execution in user agents that support [module scripts](#)<sup>p1085</sup>

[async](#)<sup>p654</sup> — Execute script when available, without blocking while fetching

[defer](#)<sup>p654</sup> — Defer script execution

[crossorigin](#)<sup>p655</sup> — How the element handles crossorigin requests

[integrity](#)<sup>p655</sup> — Integrity metadata used in *Subresource Integrity* checks [\[SRI\]](#)<sup>p1482</sup>

[referrerpolicy](#)<sup>p655</sup> — [Referrer policy](#) for [fetches](#) initiated by the element

[blocking](#)<sup>p655</sup> — Whether the element is [potentially render-blocking](#)<sup>p103</sup>

[fetchpriority](#)<sup>p655</sup> — Sets the [priority](#) for [fetches](#) initiated by the element

## Accessibility considerations<sup>p146</sup>:

[For authors.](#)

[For implementers.](#)

## DOM interface<sup>p147</sup>:

```
IDL [Exposed=Window]
interface HTMLScriptElement : HTMLElement {
    [HTMLConstructor] constructor();

    [CEReactions] attribute USVString src;
    [CEReactions] attribute DOMString type;
    [CEReactions] attribute boolean noModule;
    [CEReactions] attribute boolean async;
    [CEReactions] attribute boolean defer;

    static boolean supports(DOMString type);

    // also has obsolete members
};
```

The [script](#)<sup>p652</sup> element allows authors to include dynamic script and data blocks in their documents. The element does not [represent](#)<sup>p141</sup> content for the user.

The [type](#) attribute allows customization of the type of script represented:

- Omitting the attribute, setting it to the empty string, or setting it to a [JavaScript MIME type essence match](#), means that the script is a [classic script](#)<sup>p1085</sup>, to be interpreted according to the JavaScript [Script](#) top-level production. Classic scripts are affected by the [async](#)<sup>p654</sup> and [defer](#)<sup>p654</sup> attributes, but only when the [src](#)<sup>p654</sup> attribute is set. Authors should omit the [type](#)<sup>p653</sup> attribute instead of redundantly setting it.
- Setting the attribute to an [ASCII case-insensitive](#) match for "module" means that the script is a [JavaScript module script](#)<sup>p1085</sup>, to be interpreted according to the JavaScript [Module](#) top-level production. Module scripts are not affected by the [defer](#)<sup>p654</sup> attribute, but are affected by the [async](#)<sup>p654</sup> attribute (regardless of the state of the [src](#)<sup>p654</sup> attribute).
- Setting the attribute to an [ASCII case-insensitive](#) match for "importmap" means that the script is an [import map](#)<sup>p1107</sup>, containing JSON that will be used to control the behavior of [module specifier resolution](#)<sup>p1102</sup>. Import maps can only be inline, i.e., the [src](#)<sup>p654</sup> attribute and most other attributes are meaningless and not to be used with them.
- Setting the attribute to any other value means that the script is a **data block**, which is not processed. None of the [script](#)<sup>p652</sup> attributes (except [type](#)<sup>p653</sup> itself) have any effect on data blocks. Authors must use a [valid MIME type string](#) that is not a

[JavaScript MIME type essence match](#) to denote data blocks.

#### Note

The requirement that [data blocks](#)<sup>p653</sup> must be denoted using a [valid MIME type string](#) is in place to avoid potential future collisions. If this specification ever adds additional types of [script](#)<sup>p1084</sup>, they will be triggered by setting the [type](#)<sup>p653</sup> attribute to something which is not a MIME type, like how the "module" value denotes [module scripts](#)<sup>p1085</sup>. By using a valid MIME type string now, you ensure that your data block will not ever be reinterpreted as a different script type, even in future user agents.

[Classic scripts](#)<sup>p1085</sup> and [JavaScript module scripts](#)<sup>p1085</sup> can be embedded inline, or be imported from an external file using the [src](#) attribute, which if specified gives the [URL](#) of the external script resource to use. If [src](#)<sup>p654</sup> is specified, it must be a [valid non-empty URL potentially surrounded by spaces](#)<sup>p96</sup>.

The contents of inline [script](#)<sup>p652</sup> elements, or the external script resource, must conform with the requirements of the JavaScript specification's [Script](#) or [Module](#) productions, for [classic scripts](#)<sup>p1085</sup> and [JavaScript module scripts](#)<sup>p1085</sup> respectively. [\[JAVASCRIPT\]](#)<sup>p1479</sup>

The contents of the external script resource for [CSS module scripts](#)<sup>p1085</sup> must conform to the requirements of the CSS specification. [\[CSS\]](#)<sup>p1476</sup>

The contents of the external script resource for [JSON module scripts](#)<sup>p1085</sup> must conform to the requirements of the JSON specification. [\[JSON\]](#)<sup>p1479</sup>

The contents of inline [script](#)<sup>p652</sup> elements for [import maps](#)<sup>p1107</sup> must conform with the [import map authoring requirements](#)<sup>p1106</sup>.

For [import map](#)<sup>p1107</sup> [script](#)<sup>p652</sup> elements, the [src](#)<sup>p654</sup>, [async](#)<sup>p654</sup>, [nomodule](#)<sup>p654</sup>, [defer](#)<sup>p654</sup>, [crossorigin](#)<sup>p655</sup>, [integrity](#)<sup>p655</sup>, and [referrerpolicy](#)<sup>p655</sup> attributes must not be specified.

A document must not have more than one [import map](#)<sup>p1107</sup> [script](#)<sup>p652</sup> element.

When used to include [data blocks](#)<sup>p653</sup>, the data must be embedded inline, the format of the data must be given using the [type](#)<sup>p653</sup> attribute, and the contents of the [script](#)<sup>p652</sup> element must conform to the requirements defined for the format used. The [src](#)<sup>p654</sup>, [async](#)<sup>p654</sup>, [nomodule](#)<sup>p654</sup>, [defer](#)<sup>p654</sup>, [crossorigin](#)<sup>p655</sup>, [integrity](#)<sup>p655</sup>, [referrerpolicy](#)<sup>p655</sup>, and [fetchpriority](#)<sup>p655</sup> attributes must not be specified.

The [nomodule](#) attribute is a [boolean attribute](#)<sup>p75</sup> that prevents a script from being executed in user agents that support [module scripts](#)<sup>p1085</sup>. This allows selective execution of [module scripts](#)<sup>p1085</sup> in modern user agents and [classic scripts](#)<sup>p1085</sup> in older user agents, [as shown below](#)<sup>p657</sup>. The [nomodule](#)<sup>p654</sup> attribute must not be specified on [module scripts](#)<sup>p1085</sup> (and will be ignored if it is).

The [async](#) and [defer](#) attributes are [boolean attributes](#)<sup>p75</sup> that indicate how the script should be evaluated. [Classic scripts](#)<sup>p1085</sup> may specify [defer](#)<sup>p654</sup> or [async](#)<sup>p654</sup>, but must not specify either unless the [src](#)<sup>p654</sup> attribute is present. [Module scripts](#)<sup>p1085</sup> may specify the [async](#)<sup>p654</sup> attribute, but must not specify the [defer](#)<sup>p654</sup> attribute.

There are several possible modes that can be selected using these attributes, and depending on the script's type.

For [classic scripts](#)<sup>p1085</sup>, if the [async](#)<sup>p654</sup> attribute is present, then the classic script will be fetched [in parallel](#)<sup>p43</sup> to parsing and evaluated as soon as it is available (potentially before parsing completes). If the [async](#)<sup>p654</sup> attribute is not present but the [defer](#)<sup>p654</sup> attribute is present, then the classic script will be fetched [in parallel](#)<sup>p43</sup> and evaluated when the page has finished parsing. If neither attribute is present, then the script is fetched and evaluated immediately, blocking parsing until these are both complete.

For [module scripts](#)<sup>p1085</sup>, if the [async](#)<sup>p654</sup> attribute is present, then the module script and all its dependencies will be fetched [in parallel](#)<sup>p43</sup> to parsing, and the module script will be evaluated as soon as it is available (potentially before parsing completes). Otherwise, the module script and its dependencies will be fetched [in parallel](#)<sup>p43</sup> to parsing and evaluated when the page has finished parsing. (The [defer](#)<sup>p654</sup> attribute has no effect on module scripts.)

This is all summarized in the following schematic diagram:

**Note**

The exact processing details for these attributes are, for mostly historical reasons, somewhat non-trivial, involving a number of aspects of HTML. The implementation requirements are therefore by necessity scattered throughout the specification. The algorithms below (in this section) describe the core of this processing, but these algorithms reference and are referenced by the parsing rules for [script](#)<sup>p652</sup>, [start](#)<sup>p1328</sup> and [end](#)<sup>p1342</sup> tags in HTML, [in foreign content](#)<sup>p1357</sup>, and [in XML](#)<sup>p1385</sup>, the rules for the [document.write\(\)](#)<sup>p1153</sup> method, the handling of [scripting](#)<sup>p1072</sup>, etc.

**Note**

When inserted using the [document.write\(\)](#)<sup>p1153</sup> method, [script](#)<sup>p652</sup> elements [usually](#)<sup>p1329</sup> execute (typically blocking further script execution or HTML parsing). When inserted using the [innerHTML](#)<sup>p1158</sup> and [outerHTML](#)<sup>p1159</sup> attributes, they do not execute at all.

The [defer](#)<sup>p654</sup> attribute may be specified even if the [async](#)<sup>p654</sup> attribute is specified, to cause legacy web browsers that only support [defer](#)<sup>p654</sup> (and not [async](#)<sup>p654</sup>) to fall back to the [defer](#)<sup>p654</sup> behavior instead of the blocking behavior that is the default.

The [crossorigin](#) attribute is a [CORS settings attribute](#)<sup>p99</sup>. For [classic scripts](#)<sup>p1085</sup>, it controls whether error information will be exposed, when the script is obtained from other [origins](#)<sup>p898</sup>. For [module scripts](#)<sup>p1085</sup>, it controls the [credentials mode](#) used for cross-origin requests.

**Note**

Unlike [classic scripts](#)<sup>p1085</sup>, [module scripts](#)<sup>p1085</sup> require the use of the [CORS protocol](#) for cross-origin fetching.

The [integrity](#) attribute represents the [integrity metadata](#) for requests which this element is responsible for. The value is text. The [integrity](#)<sup>p655</sup> attribute must not be specified when the [src](#)<sup>p654</sup> attribute is not specified. [\[SRI\]](#)<sup>p1482</sup>

The [referrerpolicy](#) attribute is a [referrer policy attribute](#)<sup>p100</sup>. Its purpose is to set the [referrer policy](#) used when [fetching](#) the script, as well as any scripts imported from it. [\[REFERRERPOLICY\]](#)<sup>p1481</sup>

**Example**

An example of a [script](#)<sup>p652</sup> element's referrer policy being used when fetching imported scripts but not other subresources:

```
<script referrerpolicy="origin">
  fetch('/api/data'); // not fetched with <script>'s referrer policy
  import('./utils.mjs'); // is fetched with <script>'s referrer policy ("origin" in this case)
</script>
```

The [blocking](#) attribute is a [blocking attribute](#)<sup>p103</sup>.

The [fetchpriority](#) attribute is a [fetch priority attribute](#)<sup>p103</sup>. Its purpose is to set the [priority](#) used when [fetching](#) the script.

Changing the [src](#)<sup>p654</sup>, [type](#)<sup>p653</sup>, [nomodule](#)<sup>p654</sup>, [async](#)<sup>p654</sup>, [defer](#)<sup>p654</sup>, [crossorigin](#)<sup>p655</sup>, [integrity](#)<sup>p655</sup>, [referrerpolicy](#)<sup>p655</sup>, and [fetchpriority](#)<sup>p655</sup> attributes dynamically has no direct effect; these attributes are only used at specific times described below.

The IDL attributes [src](#), [type](#), [defer](#), [integrity](#), and [blocking](#), must each [reflect](#)<sup>p104</sup> the respective content attributes of the same name.

The **referrerPolicy** IDL attribute must [reflect](#)<sup>p104</sup> the [referrerpolicy](#)<sup>p655</sup> content attribute, [limited to only known values](#)<sup>p105</sup>.

The **fetchPriority** IDL attribute must [reflect](#)<sup>p104</sup> the [fetchpriority](#)<sup>p655</sup> content attribute, [limited to only known values](#)<sup>p105</sup>.

The **crossOrigin** IDL attribute must [reflect](#)<sup>p104</sup> the [crossorigin](#)<sup>p655</sup> content attribute, [limited to only known values](#)<sup>p105</sup>.

The **noModule** IDL attribute must [reflect](#)<sup>p104</sup> the [nomodule](#)<sup>p654</sup> content attribute.

The **async** getter steps are:

1. If [this's force async](#)<sup>p659</sup> is true, then return true.
2. If [this's async](#)<sup>p654</sup> content attribute is present, then return true.
3. Return false.

The [async](#)<sup>p656</sup> setter steps are:

1. Set [this's force async](#)<sup>p659</sup> to false.
2. If the given value is true, then set [this's async](#)<sup>p654</sup> content attribute to the empty string.
3. Otherwise, remove [this's async](#)<sup>p654</sup> content attribute.

For web developers (non-normative)

**`script.text`**<sup>p656</sup> [ = *value* ]

Returns the [child text content](#) of the element.

Can be set, to replace the element's children with the given value.

**`HTMLScriptElement.supports`**<sup>p653</sup> (*type*)

Returns true if the given *type* is a script type supported by the user agent. The possible script types in this specification are "classic", "module", and "importmap", but others might be added in the future.

The **text** attribute's getter must return this [script](#)<sup>p652</sup> element's [child text content](#).

The [text](#)<sup>p656</sup> attribute's setter must [string replace all](#) with the given value within this [script](#)<sup>p652</sup> element.

The **supports(*type*)** method steps are:

1. If *type* is "classic", then return true.
2. If *type* is "module", then return true.
3. If *type* is "importmap", then return true.
4. Return false.

#### Note

The *type* argument has to exactly match these values; we do not perform an [ASCII case-insensitive](#) match. This is different from how [type](#)<sup>p653</sup> content attribute values are treated, and how [DOMTokenList](#)'s [supports\(\)](#) method works, but it aligns with the [WorkerType](#)<sup>p1236</sup> enumeration used in the [Worker\(\)](#)<sup>p1236</sup> constructor.

#### Example

In this example, two [script](#)<sup>p652</sup> elements are used. One embeds an external [classic script](#)<sup>p1085</sup>, and the other includes some data as a [data block](#)<sup>p653</sup>.

```
<script src="game-engine.js"></script>
<script type="text/x-game-map">
  .....U.....e
  o.....A....e
  ....A....AAA...e
  .A..AAA..AAAAA...e
</script>
```

The data in this case might be used by the script to generate the map of a video game. The data doesn't have to be used that way, though; maybe the map data is actually embedded in other parts of the page's markup, and the data block here is just used by the site's search engine to help users who are looking for particular features in their game maps.

#### Example

The following sample shows how a [script](#)<sup>p652</sup> element can be used to define a function that is then used by other parts of the document, as part of a [classic script](#)<sup>p1085</sup>. It also shows how a [script](#)<sup>p652</sup> element can be used to invoke script while the document is being parsed, in this case to initialize the form's output.

```
<script>
function calculate(form) {
  var price = 52000;
  if (form.elements.brakes.checked)
    price += 1000;
  if (form.elements.radio.checked)
    price += 2500;
  if (form.elements.turbo.checked)
    price += 5000;
  if (form.elements.sticker.checked)
    price += 250;
  form.elements.result.value = price;
}
</script>
<form name="pricecalc" onsubmit="return false" onchange="calculate(this)">
  <fieldset>
    <legend>Work out the price of your car</legend>
    <p>Base cost: £52000.</p>
    <p>Select additional options:</p>
    <ul>
      <li><label><input type="checkbox" name="brakes"> Ceramic brakes (£1000)</label></li>
      <li><label><input type="checkbox" name="radio"> Satellite radio (£2500)</label></li>
      <li><label><input type="checkbox" name="turbo"> Turbo charger (£5000)</label></li>
      <li><label><input type="checkbox" name="sticker"> "XZ" sticker (£250)</label></li>
    </ul>
    <p>Total: £<output name="result"></output></p>
  </fieldset>
  <script>
    calculate(document.forms.pricecalc);
  </script>
</form>
```

#### Example

The following sample shows how a [script](#)<sup>p652</sup> element can be used to include an external [JavaScript module script](#)<sup>p1085</sup>.

```
<script type="module" src="app.mjs"></script>
```

This module, and all its dependencies (expressed through JavaScript `import` statements in the source file), will be fetched. Once the entire resulting module graph has been imported, and the document has finished parsing, the contents of `app.mjs` will be evaluated.

Additionally, if code from another [script](#)<sup>p652</sup> element in the same [Window](#)<sup>p922</sup> imports the module from `app.mjs` (e.g. via `import ". /app.mjs";`), then the same [JavaScript module script](#)<sup>p1085</sup> created by the former [script](#)<sup>p652</sup> element will be imported.

#### Example

This example shows how to include a [JavaScript module script](#)<sup>p1085</sup> for modern user agents, and a [classic script](#)<sup>p1085</sup> for older user agents:

```
<script type="module" src="app.mjs"></script>
<script nomodule defer src="classic-app-bundle.js"></script>
```

In modern user agents that support [JavaScript module scripts](#)<sup>p1085</sup>, the [script](#)<sup>p652</sup> element with the [nomodule](#)<sup>p654</sup> attribute will be ignored, and the [script](#)<sup>p652</sup> element with a [type](#)<sup>p653</sup> of "module" will be fetched and evaluated (as a [JavaScript module script](#)<sup>p1085</sup>). Conversely, older user agents will ignore the [script](#)<sup>p652</sup> element with a [type](#)<sup>p653</sup> of "module", as that is an unknown script type for them — but they will have no problem fetching and evaluating the other [script](#)<sup>p652</sup> element (as a [classic script](#)<sup>p1085</sup>), since they do not implement the [nomodule](#)<sup>p654</sup> attribute.

#### Example

The following sample shows how a [script](#)<sup>p652</sup> element can be used to write an inline [JavaScript module script](#)<sup>p1085</sup> that performs a number of substitutions on the document's text, in order to make for a more interesting reading experience (e.g. on a news site): [\[XKCD1288\]](#)<sup>p1484</sup>

```
<script type="module">
  import { walkAllTextNodeDescendants } from "./dom-utils.mjs";

  const substitutions = new Map([
    ["witnesses", "these dudes I know"]
    ["allegedly", "kinda probably"]
    ["new study", "Tumblr post"]
    ["rebuild", "avenge"]
    ["space", "spaaace"]
    ["Google glass", "Virtual Boy"]
    ["smartphone", "Pokédex"]
    ["electric", "atomic"]
    ["Senator", "Elf-Lord"]
    ["car", "cat"]
    ["election", "eating contest"]
    ["Congressional leaders", "river spirits"]
    ["homeland security", "Homestar Runner"]
    ["could not be reached for comment", "is guilty and everyone knows it"]
  ]);

  function substitute(textNode) {
    for (const [before, after] of substitutions.entries()) {
      textNode.data = textNode.data.replace(new RegExp(`\\b${before}\\b`, "ig"), after);
    }
  }

  walkAllTextNodeDescendants(document.body, substitute);
</script>
```

Some notable features gained by using a JavaScript module script include the ability to import functions from other JavaScript modules, strict mode by default, and how top-level declarations do not introduce new properties onto the [global object](#)<sup>p1076</sup>. Also note that no matter where this [script](#)<sup>p652</sup> element appears in the document, it will not be evaluated until both document parsing has complete and its dependency (dom-utils.mjs) has been fetched and evaluated.

#### Example

The following sample shows how a [JSON module script](#)<sup>p1085</sup> can be imported from inside a [JavaScript module script](#)<sup>p1085</sup>:

```
<script type="module">
  import peopleInSpace from "http://api.open-notify.org/astros.json" with { type: "json" };

  const list = document.querySelector("#people-in-space");
  for (const { craft, name } of peopleInSpace.people) {
    const li = document.createElement("li");
    li.textContent = `${name} / ${craft}`;
  }
</script>
```

```
list.append(li);
}
</script>
```

MIME type checking for module scripts is strict. In order for the fetch of the [JSON module script](#)<sup>p1085</sup> to succeed, the HTTP response must have a [JSON MIME type](#), for example Content-Type: text/json. On the other hand, if the with { type: "json" } part of the statement is omitted, it is assumed that the intent is to import a [JavaScript module script](#)<sup>p1085</sup>, and the fetch will fail if the HTTP response has a MIME type that is not a [JavaScript MIME type](#).

#### 4.12.1.1 Processing model <sup>§ p65</sup><sub>9</sub>

A [script](#)<sup>p652</sup> element has several associated pieces of state.

A [script](#)<sup>p652</sup> element has a **parser document**, which is either null or a [Document](#)<sup>p130</sup>, initially null. It is set by the [HTML parser](#)<sup>p1271</sup> and the [XML parser](#)<sup>p1384</sup> on [script](#)<sup>p652</sup> elements they insert, and affects the processing of those elements. [script](#)<sup>p652</sup> elements with non-null [parser documents](#)<sup>p659</sup> are known as **parser-inserted**.

A [script](#)<sup>p652</sup> element has a **preparation-time document**, which is either null or a [Document](#)<sup>p130</sup>, initially null. It is used to prevent scripts that move between documents during [preparation](#)<sup>p661</sup> from [executing](#)<sup>p665</sup>.

A [script](#)<sup>p652</sup> element has a **force async** boolean, initially true. It is set to false by the [HTML parser](#)<sup>p1271</sup> and the [XML parser](#)<sup>p1384</sup> on [script](#)<sup>p652</sup> elements they insert, and when the element gets an [async](#)<sup>p654</sup> content attribute added.

A [script](#)<sup>p652</sup> element has a **from an external file** boolean, initially false. It is determined when the script is [prepared](#)<sup>p661</sup>, based on the [src](#)<sup>p654</sup> attribute of the element at that time.

A [script](#)<sup>p652</sup> element has a **ready to be parser-executed** boolean, initially false. This is used only used for elements that are also [parser-inserted](#)<sup>p659</sup>, to let the parser know when to execute the script.

A [script](#)<sup>p652</sup> element has an **already started** boolean, initially false.

A [script](#)<sup>p652</sup> element has a **delaying the load event** boolean, initially false.

A [script](#)<sup>p652</sup> element has a **type**, which is either null, "classic", "module", or "importmap", initially null. It is determined when the element is [prepared](#)<sup>p661</sup>, based on the [type](#)<sup>p653</sup> attribute of the element at that time.

A [script](#)<sup>p652</sup> element has a **result**, which is either "uninitialized", null (representing an error), a [script](#)<sup>p1084</sup>, or an [import map parse result](#)<sup>p1101</sup>. It is initially "uninitialized".

A [script](#)<sup>p652</sup> element has **steps to run when the result is ready**, which are a series of steps or null, initially null. To **mark as ready** a [script](#)<sup>p652</sup> element *e*/ given a [script](#)<sup>p1084</sup>, [import map parse result](#)<sup>p1101</sup>, or null *result*:

1. Set *e*'s [result](#)<sup>p659</sup> to *result*.
2. If *e*'s [steps to run when the result is ready](#)<sup>p659</sup> are not null, then run them.
3. Set *e*'s [steps to run when the result is ready](#)<sup>p659</sup> to null.
4. Set *e*'s [delaying the load event](#)<sup>p659</sup> to false.

A [script](#)<sup>p652</sup> element *e*/ is [implicitly potentially render-blocking](#)<sup>p103</sup> if *e*'s [type](#)<sup>p659</sup> is "classic", *e*/ is [parser-inserted](#)<sup>p659</sup>, and *e*/ does not have an [async](#)<sup>p654</sup> or [defer](#)<sup>p654</sup> attribute.

The [cloning steps](#) for a [script](#)<sup>p652</sup> element *e*/ being cloned to a copy *copy* are to set *copy*'s [already started](#)<sup>p659</sup> to *e*'s [already started](#)<sup>p659</sup>.

When an [async](#)<sup>p654</sup> attribute is added to a [script](#)<sup>p652</sup> element *e*/, the user agent must set *e*'s [force async](#)<sup>p659</sup> to false.

Whenever a [script](#)<sup>p652</sup> element *e*'s [delaying the load event](#)<sup>p659</sup> is true, the user agent must [delay the load event](#)<sup>p1359</sup> of *e*'s [preparation-time document](#)<sup>p659</sup>.

The [script<sup>p652</sup>](#) [HTML element post-connection steps<sup>p45</sup>](#), given *insertedNode*, are:

1. If *insertedNode* is not [connected](#), then return.

#### Example

This can happen in the case where an earlier-inserted [script<sup>p652</sup>](#) removes a later-inserted [script<sup>p652</sup>](#). For instance:

```
<script>
const script1 = document.createElement('script');
script1.innerText = `
  document.querySelector('#script2').remove();
`;

const script2 = document.createElement('script');
script2.id = 'script2';
script2.textContent = `console.log('script#2 running')`;

document.body.append(script1, script2);
</script>
```

Nothing is printed to the console in this example. By the time the [HTML element post-connection steps<sup>p45</sup>](#) run for the first [script<sup>p652</sup>](#) that was atomically inserted by `append()`, it can observe that the second [script<sup>p652</sup>](#) is already [connected](#) to the DOM. It removes the second [script<sup>p652</sup>](#), so that by the time its [HTML element post-connection steps<sup>p45</sup>](#) run, it is no longer [connected](#), and does not get [prepared<sup>p661</sup>](#).

2. If *insertedNode* is [parser-inserted<sup>p659</sup>](#), then return.
3. [Prepare the script element<sup>p661</sup>](#) given *insertedNode*.

The [script<sup>p652</sup>](#) [children changed steps](#) are:

1. Run the [script<sup>p652</sup>](#) [HTML element post-connection steps<sup>p45</sup>](#), given the [script<sup>p652</sup>](#) element.

#### Example

This has an interesting implication on the execution order of a [script<sup>p652</sup>](#) element and any newly-inserted child [script<sup>p652</sup>](#) elements. Consider the following snippet:

```
<script id=outer-script></script>

<script>
  const outerScript = document.querySelector('#outer-script');

  const start = new Text('console.log(1);');
  const innerScript = document.createElement('script');
  innerScript.textContent = `console.log('inner script executing')`;
  const end = new Text('console.log(2);');

  outerScript.append(start, innerScript, end);

  // Logs:
  // 1
  // 2
  // inner script executing
</script>
```

By the time the second script block executes, the `outer-script` has already been [prepared<sup>p661</sup>](#), but because it is empty, it did not execute and therefore is not marked as [already started<sup>p659</sup>](#). The atomic insertion of the `Text` nodes and nested [script<sup>p652</sup>](#) element have the following effects:

1. All three child nodes get atomically inserted as children of `outer-script`; all of their [insertion steps](#) run, which have no observable consequences in this case.

2. The outer-script's [children changed steps](#) run, which [prepares](#)<sup>p661</sup> that script; because its body is now non-empty, this executes the contents of the two [Text](#) nodes, in order.
3. The [script](#)<sup>p652</sup> [HTML element post-connection steps](#)<sup>p45</sup> finally run for innerScript, causing its body to execute.

The following [attribute change steps](#), given *element*, *localName*, *oldValue*, *value*, and *namespace*, are used for all [script](#)<sup>p652</sup> elements:

1. If *namespace* is not null, then return.
2. If *localName* is [src](#)<sup>p654</sup>, then run the [script](#)<sup>p652</sup> [HTML element post-connection steps](#)<sup>p45</sup>, given *element*.

To **prepare the script element** given a [script](#)<sup>p652</sup> element *el*:

1. If *el*'s [already started](#)<sup>p659</sup> is true, then return.
2. Let *parser document* be *el*'s [parser document](#)<sup>p659</sup>.
3. Set *el*'s [parser document](#)<sup>p659</sup> to null.

#### Note

*This is done so that if parser-inserted [script](#)<sup>p652</sup> elements fail to run when the parser tries to run them, e.g. because they are empty or specify an unsupported scripting language, another script can later mutate them and cause them to run again.*

4. If *parser document* is non-null and *el* does not have an [async](#)<sup>p654</sup> attribute, then set *el*'s [force async](#)<sup>p659</sup> to true.

#### Note

*This is done so that if a parser-inserted [script](#)<sup>p652</sup> element fails to run when the parser tries to run it, but it is later executed after a script dynamically updates it, it will execute in an async fashion even if the [async](#)<sup>p654</sup> attribute isn't set.*

5. Let *source text* be *el*'s [child text content](#).
6. If *el* has no [src](#)<sup>p654</sup> attribute, and *source text* is the empty string, then return.
7. If *el* is not [connected](#), then return.
8. If any of the following are true:
  - *el* has a [type](#)<sup>p653</sup> attribute whose value is the empty string;
  - *el* has no [type](#)<sup>p653</sup> attribute but it has a [language](#)<sup>p1429</sup> attribute and *that* attribute's value is the empty string; or
  - *el* has neither a [type](#)<sup>p653</sup> attribute nor a [language](#)<sup>p1429</sup> attribute,

then let *the script block's type string* for this [script](#)<sup>p652</sup> element be "text/javascript".

Otherwise, if *el* has a [type](#)<sup>p653</sup> attribute, then let *the script block's type string* be the value of that attribute with [leading and trailing ASCII whitespace stripped](#).

Otherwise, *el* has a non-empty [language](#)<sup>p1429</sup> attribute; let *the script block's type string* be the concatenation of "text/" and the value of *el*'s [language](#)<sup>p1429</sup> attribute.

#### Note

*The [language](#)<sup>p1429</sup> attribute is never conforming, and is always ignored if there is a [type](#)<sup>p653</sup> attribute present.*

9. If *the script block's type string* is a [JavaScript MIME type essence match](#), then set *el*'s [type](#)<sup>p659</sup> to "classic".
10. Otherwise, if *the script block's type string* is an [ASCII case-insensitive](#) match for the string "module", then set *el*'s [type](#)<sup>p659</sup> to "module".
11. Otherwise, if *the script block's type string* is an [ASCII case-insensitive](#) match for the string "importmap", then set *el*'s [type](#)<sup>p659</sup> to "importmap".
12. Otherwise, return. (No script is executed, and *el*'s [type](#)<sup>p659</sup> is left as null.)

13. If *parser document* is non-null, then set *el*'s [parser document](#)<sup>p659</sup> back to *parser document* and set *el*'s [force\\_async](#)<sup>p659</sup> to false.
14. Set *el*'s [already\\_started](#)<sup>p659</sup> to true.
15. Set *el*'s [preparation-time document](#)<sup>p659</sup> to its [node document](#).
16. If *parser document* is non-null, and *parser document* is not equal to *el*'s [preparation-time document](#)<sup>p659</sup>, then return.
17. If [scripting is disabled](#)<sup>p1083</sup> for *el*, then return.

**Note**

The definition of [scripting is disabled](#)<sup>p1083</sup> means that, amongst others, the following scripts will not execute: scripts in XMLHttpRequest's [responseXML](#) documents, scripts in DOMParser<sup>p1154</sup>-created documents, scripts in documents created by XSLTProcessor<sup>p51</sup>'s [transformToDocument](#)<sup>p51</sup> feature, and scripts that are first inserted by a script into a Document<sup>p138</sup> that was created using the [createDocument\(\)](#) API. [XHR]<sup>p1484</sup> [DOMPARSING]<sup>p1478</sup> [XSLTP]<sup>p1484</sup> [DOM]<sup>p1478</sup>

18. If *el* has a [nomodule](#)<sup>p654</sup> content attribute and its [type](#)<sup>p659</sup> is "classic", then return.

**Note**

This means specifying [nomodule](#)<sup>p654</sup> on a [module script](#)<sup>p1085</sup> has no effect; the algorithm continues onward.

19. If *el* does not have a [src](#)<sup>p654</sup> content attribute, and the [Should element's inline behavior be blocked by Content Security Policy?](#) algorithm returns "Blocked" when given *el*, "script", and *source text*, then return. [CSP]<sup>p1476</sup>
20. If *el* has an [event](#)<sup>p1429</sup> attribute and a [for](#)<sup>p1429</sup> attribute, and *el*'s [type](#)<sup>p659</sup> is "classic", then:
  1. Let *for* be the value of *el*'s [for](#)<sup>p1429</sup> attribute.
  2. Let *event* be the value of *el*'s [event](#)<sup>p1429</sup> attribute.
  3. Strip leading and trailing ASCII whitespace from *event* and *for*.
  4. If *for* is not an ASCII case-insensitive match for the string "window", then return.
  5. If *event* is not an ASCII case-insensitive match for either the string "onload" or the string "onload()", then return.
21. If *el* has a [charset](#)<sup>p1427</sup> attribute, then let *encoding* be the result of [getting an encoding](#) from the value of the [charset](#)<sup>p1427</sup> attribute.

If *el* does not have a [charset](#)<sup>p1427</sup> attribute, or if [getting an encoding](#) failed, then let *encoding* be *el*'s [node document](#)'s [the encoding](#).

**Note**

If *el*'s [type](#)<sup>p659</sup> is "module", this encoding will be ignored.

22. Let *classic script CORS setting* be the current state of *el*'s [crossorigin](#)<sup>p655</sup> content attribute.
23. Let *module script credentials mode* be the [CORS settings attribute credentials mode](#)<sup>p99</sup> for *el*'s [crossorigin](#)<sup>p655</sup> content attribute.
24. Let *cryptographic nonce* be *el*'s [[CryptographicNonce]]<sup>p100</sup> internal slot's value.
25. If *el* has an [integrity](#)<sup>p655</sup> attribute, then let *integrity metadata* be that attribute's value.  
Otherwise, let *integrity metadata* be the empty string.
26. Let *referrer policy* be the current state of *el*'s [referrerpolicy](#)<sup>p655</sup> content attribute.
27. Let *fetch priority* be the current state of *el*'s [fetchpriority](#)<sup>p655</sup> content attribute.
28. Let *parser metadata* be "parser-inserted" if *el* is [parser-inserted](#)<sup>p659</sup>, and "not-parser-inserted" otherwise.
29. Let *options* be a [script fetch options](#)<sup>p1085</sup> whose [cryptographic nonce](#)<sup>p1086</sup> is *cryptographic nonce*, [integrity metadata](#)<sup>p1086</sup> is *integrity metadata*, [parser metadata](#)<sup>p1086</sup> is *parser metadata*, [credentials mode](#)<sup>p1086</sup> is *module script credentials mode*, [referrer policy](#)<sup>p1086</sup> is *referrer policy*, and [fetch priority](#)<sup>p1086</sup> is *fetch priority*.
30. Let *settings object* be *el*'s [node document](#)'s [relevant settings object](#)<sup>p1083</sup>.

31. If *e* has a [src<sup>p654</sup>](#) content attribute, then:

1. If *e*'s [type<sup>p659</sup>](#) is "importmap", then [queue an element task<sup>p1125</sup>](#) on the [DOM manipulation task source<sup>p1134</sup>](#) given *e* to [fire an event](#) named [error<sup>p1471</sup>](#) at *e*, and return.

**Note**

*External import map scripts are not currently supported. See [WICG/import-maps issue #235](#) for discussions on adding support.*

2. Let *src* be the value of *e*'s [src<sup>p654</sup>](#) attribute.
3. If *src* is the empty string, then [queue an element task<sup>p1125</sup>](#) on the [DOM manipulation task source<sup>p1134</sup>](#) given *e* to [fire an event](#) named [error<sup>p1471</sup>](#) at *e*, and return.
4. Set *e*'s [from an external file<sup>p659</sup>](#) to true.
5. Let *url* be the result of [encoding-parsing a URL<sup>p97</sup>](#) given *src*, relative to *e*'s [node document](#).
6. If *url* is failure, then [queue an element task<sup>p1125</sup>](#) on the [DOM manipulation task source<sup>p1134</sup>](#) given *e* to [fire an event](#) named [error<sup>p1471</sup>](#) at *e*, and return.
7. If *e* is [potentially render-blocking<sup>p103</sup>](#), then [block rendering<sup>p134</sup>](#) on *e*.
8. Set *e*'s [delaying the load event<sup>p659</sup>](#) to true.
9. If *e* is currently [render-blocking<sup>p134</sup>](#), then set *options*'s [render-blocking<sup>p1086</sup>](#) to true.
10. Let *onComplete* given *result* be the following steps:
  1. [Mark as ready<sup>p659</sup>](#) *e* given *result*.
11. Switch on *e*'s [type<sup>p659</sup>](#):

↪ "classic"

[Fetch a classic script<sup>p1087</sup>](#) given *url*, *settings object*, *options*, *classic script CORS setting*, *encoding*, and *onComplete*.

↪ "module"

If *e* does not have an [integrity<sup>p655</sup>](#) attribute, then set *options*'s [integrity metadata<sup>p1086</sup>](#) to the result of [resolving a module integrity metadata<sup>p1086</sup>](#) with *url* and *settings object*.

[Fetch an external module script graph<sup>p1089</sup>](#) given *url*, *settings object*, *options*, and *onComplete*.

For performance reasons, user agents may start fetching the classic script or module graph (as defined above) as soon as the [src<sup>p654</sup>](#) attribute is set, instead, in the hope that *e* will become connected (and that the [crossorigin<sup>p655</sup>](#) attribute won't change value in the meantime). Either way, once *e* [becomes connected<sup>p46</sup>](#), the load must have started as described in this step. If the UA performs such prefetching, but *e* never becomes connected, or the [src<sup>p654</sup>](#) attribute is dynamically changed, or the [crossorigin<sup>p655</sup>](#) attribute is dynamically changed, then the user agent will not execute the script so obtained, and the fetching process will have been effectively wasted.

32. If *e* does not have a [src<sup>p654</sup>](#) content attribute:

1. Let *base URL* be *e*'s [node document](#)'s [document base URL<sup>p96</sup>](#).
2. Switch on *e*'s [type<sup>p659</sup>](#):
  - ↪ "classic"
    1. Let *script* be the result of [creating a classic script<sup>p1093</sup>](#) using *source text*, *settings object*, *base URL*, and *options*.
    2. [Mark as ready<sup>p659</sup>](#) *e* given *script*.
  - ↪ "module"
    1. Set *e*'s [delaying the load event<sup>p659</sup>](#) to true.
    2. If *e* is [potentially render-blocking<sup>p103</sup>](#), then:

1. [Block rendering](#)<sup>p134</sup> on *el*.
2. Set *options*'s [render-blocking](#)<sup>p1086</sup> to true.
3. [Fetch an inline module script graph](#)<sup>p1090</sup>, given *source text*, *base URL*, *settings object*, *options*, and with the following steps given *result*:
  1. [Queue an element task](#)<sup>p1125</sup> on the [networking task source](#)<sup>p1134</sup> given *el* to perform the following steps:
    1. [Mark as ready](#)<sup>p659</sup> *el* given *result*.

#### Note

*Queueing a task here means that, even if the inline module script has no dependencies or synchronously results in a parse error, we won't proceed to [execute the script element](#)<sup>p665</sup> synchronously.*

↪ "importmap"

1. Let *result* be the result of [creating an import map parse result](#)<sup>p1101</sup> given *source text* and *base URL*.
  2. [Mark as ready](#)<sup>p659</sup> *el* given *result*.
33. If *el*'s [type](#)<sup>p659</sup> is "classic" and *el* has a [src](#)<sup>p654</sup> attribute, or *el*'s [type](#)<sup>p659</sup> is "module":
1. [Assert](#): *el*'s [result](#)<sup>p659</sup> is "uninitialized".
  2. If *el* has an [async](#)<sup>p654</sup> attribute or *el*'s [force async](#)<sup>p659</sup> is true:
    1. Let *scripts* be *el*'s [preparation-time document](#)<sup>p659</sup>'s [set of scripts that will execute as soon as possible](#)<sup>p665</sup>.
    2. [Append](#) *el* to *scripts*.
    3. Set *el*'s [steps to run when the result is ready](#)<sup>p659</sup> to the following:
      1. [Execute the script element](#)<sup>p665</sup> *el*.
      2. [Remove](#) *el* from *scripts*.
  3. Otherwise, if *el* is not [parser-inserted](#)<sup>p659</sup>:
    1. Let *scripts* be *el*'s [preparation-time document](#)<sup>p659</sup>'s [list of scripts that will execute in order as soon as possible](#)<sup>p665</sup>.
    2. [Append](#) *el* to *scripts*.
    3. Set *el*'s [steps to run when the result is ready](#)<sup>p659</sup> to the following:
      1. If *scripts*[0] is not *el*, then abort these steps.
      2. While *scripts* is not empty, and *scripts*[0]'s [result](#)<sup>p659</sup> is not "uninitialized":
        1. [Execute the script element](#)<sup>p665</sup> *scripts*[0].
        2. [Remove](#) *scripts*[0].
  4. Otherwise, if *el* has a [defer](#)<sup>p654</sup> attribute or *el*'s [type](#)<sup>p659</sup> is "module":
    1. [Append](#) *el* to its [parser document](#)<sup>p659</sup>'s [list of scripts that will execute when the document has finished parsing](#)<sup>p665</sup>.
    2. Set *el*'s [steps to run when the result is ready](#)<sup>p659</sup> to the following: set *el*'s [ready to be parser-executed](#)<sup>p659</sup> to true. (The parser will handle executing the script.)
  5. Otherwise:
    1. Set *el*'s [parser document](#)<sup>p659</sup>'s [pending parsing-blocking script](#)<sup>p665</sup> to *el*.
    2. [Block rendering](#)<sup>p134</sup> on *el*.

3. Set *el*'s [steps to run when the result is ready](#)<sup>p659</sup> to the following: set *el*'s [ready to be parser-executed](#)<sup>p659</sup> to true. (The parser will handle executing the script.)

34. Otherwise:

1. **Assert:** *el*'s [result](#)<sup>p659</sup> is not "uninitialized".
2. If all of the following are true:
  - *el*'s [type](#)<sup>p659</sup> is "classic";
  - *el* is [parser-inserted](#)<sup>p659</sup>;
  - *el*'s [parser document](#)<sup>p659</sup> [has a style sheet that is blocking scripts](#)<sup>p204</sup>; and
  - either the parser that created *el* is an [XML parser](#)<sup>p1384</sup>, or it's an [HTML parser](#)<sup>p1271</sup> whose [script nesting level](#)<sup>p1273</sup> is not greater than one,

then:

1. Set *el*'s [parser document](#)<sup>p659</sup>'s [pending parsing-blocking script](#)<sup>p665</sup> to *el*.
2. Set *el*'s [ready to be parser-executed](#)<sup>p659</sup> to true. (The parser will handle executing the script.)
3. Otherwise, [immediately](#)<sup>p43</sup> [execute the script element](#)<sup>p665</sup> *el*, even if other scripts are already executing.

Each [Document](#)<sup>p130</sup> has a **pending parsing-blocking script**, which is a [script](#)<sup>p652</sup> element or null, initially null.

Each [Document](#)<sup>p130</sup> has a **set of scripts that will execute as soon as possible**, which is a [set](#) of [script](#)<sup>p652</sup> elements, initially empty.

Each [Document](#)<sup>p130</sup> has a **list of scripts that will execute in order as soon as possible**, which is a [list](#) of [script](#)<sup>p652</sup> elements, initially empty.

Each [Document](#)<sup>p130</sup> has a **list of scripts that will execute when the document has finished parsing**, which is a [list](#) of [script](#)<sup>p652</sup> elements, initially empty.

#### Note

*If a [script](#)<sup>p652</sup> element that blocks a parser gets moved to another [Document](#)<sup>p130</sup> before it would normally have stopped blocking that parser, it nonetheless continues blocking that parser until the condition that causes it to be blocking the parser no longer applies (e.g., if the script is a [pending parsing-blocking script](#)<sup>p665</sup> because the original [Document](#)<sup>p130</sup> [has a style sheet that is blocking scripts](#)<sup>p204</sup> when it was parsed, but then the script is moved to another [Document](#)<sup>p130</sup> before the blocking style sheet(s) loaded, the script still blocks the parser until the style sheets are all loaded, at which time the script executes and the parser is unblocked).*

To **execute the script element** given a [script](#)<sup>p652</sup> element *el*:

1. Let *document* be *el*'s [node document](#).
2. If *el*'s [preparation-time document](#)<sup>p659</sup> is not equal to *document*, then return.
3. [Unblock rendering](#)<sup>p135</sup> on *el*.
4. If *el*'s [result](#)<sup>p659</sup> is null, then [fire an event](#) named [error](#)<sup>p1471</sup> at *el*, and return.
5. If *el*'s [from an external file](#)<sup>p659</sup> is true, or *el*'s [type](#)<sup>p659</sup> is "module", then increment *document*'s [ignore-destructive-writes counter](#)<sup>p1152</sup>.
6. Switch on *el*'s [type](#)<sup>p659</sup>:
  - ↪ "classic"
    1. Let *oldCurrentScript* be the value to which *document*'s [currentScript](#)<sup>p137</sup> object was most recently set.
    2. If *el*'s [root](#) is not a [shadow root](#), then set *document*'s [currentScript](#)<sup>p137</sup> attribute to *el*. Otherwise, set it to null.

#### Note

This does not use the [in a document tree](#) check, as `el` could have been removed from the document prior to execution, and in that scenario `currentScript`<sup>p137</sup> still needs to point to it.

3. [Run the classic script](#)<sup>p1096</sup> given by `el`'s `result`<sup>p659</sup>.
4. Set `document`'s `currentScript`<sup>p137</sup> attribute to `oldCurrentScript`.

↪ "module"

1. [Assert](#): `document`'s `currentScript`<sup>p137</sup> attribute is null.
2. [Run the module script](#)<sup>p1096</sup> given by `el`'s `result`<sup>p659</sup>.

↪ "importmap"

1. [Register an import map](#)<sup>p1101</sup> given `el`'s [relevant global object](#)<sup>p1083</sup> and `el`'s `result`<sup>p659</sup>.
7. Decrement the [ignore-destructive-writes counter](#)<sup>p1152</sup> of `document`, if it was incremented in the earlier step.
8. If `el`'s [from an external file](#)<sup>p659</sup> is true, then [fire an event](#) named `load`<sup>p1471</sup> at `el`.

#### 4.12.1.2 Scripting languages §<sup>p66</sup><sub>6</sub>

User agents are not required to support JavaScript. This standard needs to be updated if a language other than JavaScript comes along and gets similar wide adoption by web browsers. Until such a time, implementing other languages is in conflict with this standard, given the processing model defined for the `script`<sup>p652</sup> element.

Servers should use `text/javascript`<sup>p1474</sup> for JavaScript resources, in accordance with *Updates to ECMAScript Media Types*. Servers should not use other [JavaScript MIME types](#) for JavaScript resources, and must not use non-[JavaScript MIME types](#). [\[RFC9239\]](#)<sup>p1481</sup>

For external JavaScript resources, MIME type parameters in ``Content-Type``<sup>p98</sup> headers are generally ignored. (In some cases the ``charset`` parameter has an effect.) However, for the `script`<sup>p652</sup> element's `type`<sup>p653</sup> attribute they are significant; it uses the [JavaScript MIME type essence match](#) concept.

#### Note

For example, scripts with their `type`<sup>p653</sup> attribute set to `"text/javascript; charset=utf-8"` will not be evaluated, even though that is a valid [JavaScript MIME type](#) when parsed.

Furthermore, again for external JavaScript resources, special considerations apply around ``Content-Type``<sup>p98</sup> header processing as detailed in the [prepare the script element](#)<sup>p661</sup> algorithm and [Fetch](#). [\[FETCH\]](#)<sup>p1478</sup>

#### 4.12.1.3 Restrictions for contents of `script` elements §<sup>p66</sup><sub>6</sub>

#### Note

The easiest and safest way to avoid the rather strange restrictions described in this section is to always escape an ASCII case-insensitive match for `"<!--"` as `"\x3C!--"`, `"<script"` as `"\x3Cscript"`, and `"</script"` as `"\x3C/script"` when these sequences appear in literals in scripts (e.g. in strings, regular expressions, or comments), and to avoid writing code that uses such constructs in expressions. Doing so avoids the pitfalls that the restrictions in this section are prone to triggering: namely, that, for historical reasons, parsing of `script`<sup>p652</sup> blocks in HTML is a strange and exotic practice that acts unintuitively in the face of these sequences.

The `script`<sup>p652</sup> element's [descendant text content](#) must match the `script` production in the following ABNF, the character set for which is Unicode. [\[ABNF\]](#)<sup>p1475</sup>

```
script      = outer *( comment-open inner comment-close outer )
outer       = < any string that doesn't contain a substring that matches not-in-outer >
not-in-outer = comment-open
```

```

inner      = < any string that doesn't contain a substring that matches not-in-inner >
not-in-inner = comment-close / script-open

comment-open = "<!--"
comment-close = "-->"
script-open  = "<script>"

s      = %x0053 ; U+0053 LATIN CAPITAL LETTER S
s      = / %x0073 ; U+0073 LATIN SMALL LETTER S
c      = %x0043 ; U+0043 LATIN CAPITAL LETTER C
c      = / %x0063 ; U+0063 LATIN SMALL LETTER C
r      = %x0052 ; U+0052 LATIN CAPITAL LETTER R
r      = / %x0072 ; U+0072 LATIN SMALL LETTER R
i      = %x0049 ; U+0049 LATIN CAPITAL LETTER I
i      = / %x0069 ; U+0069 LATIN SMALL LETTER I
p      = %x0050 ; U+0050 LATIN CAPITAL LETTER P
p      = / %x0070 ; U+0070 LATIN SMALL LETTER P
t      = %x0054 ; U+0054 LATIN CAPITAL LETTER T
t      = / %x0074 ; U+0074 LATIN SMALL LETTER T

tag-end   = %x0009 ; U+0009 CHARACTER TABULATION (tab)
tag-end   = / %x000A ; U+000A LINE FEED (LF)
tag-end   = / %x000C ; U+000C FORM FEED (FF)
tag-end   = / %x0020 ; U+0020 SPACE
tag-end   = / %x002F ; U+002F SOLIDUS (/)
tag-end   = / %x003E ; U+003E GREATER-THAN SIGN (>)

```

When a [script](#)<sup>p652</sup> element contains [script documentation](#)<sup>p668</sup>, there are further restrictions on the contents of the element, as described in the section below.

#### Example

The following script illustrates this issue. Suppose you have a script that contains a string, as in:

```

const example = 'Consider this string: <!-- <script>';
console.log(example);

```

If one were to put this string directly in a [script](#)<sup>p652</sup> block, it would violate the restrictions above:

```

<script>
  const example = 'Consider this string: <!-- <script>';
  console.log(example);
</script>

```

The bigger problem, though, and the reason why it would violate those restrictions, is that actually the script would get parsed weirdly: *the script block above is not terminated*. That is, what looks like a "`</script>`" end tag in this snippet is actually still part of the [script](#)<sup>p652</sup> block. The script doesn't execute (since it's not terminated); if it somehow were to execute, as it might if the markup looked as follows, it would fail because the script (highlighted here) is not valid JavaScript:

```

<script>
  const example = 'Consider this string: <!-- <script>';
  console.log(example);
</script>
<!-- despite appearances, this is actually part of the script still! -->
<script>
  ... // this is the same script block still...
</script>

```

What is going on here is that for legacy reasons, "`<!--`" and "`<script`" strings in [script](#)<sup>p652</sup> elements in HTML need to be balanced in order for the parser to consider closing the block.

By escaping the problematic strings as mentioned at the top of this section, the problem is avoided entirely:

```
<script>
  // Note: `\"x3C` is an escape sequence for `<`.
  const example = 'Consider this string: \"x3C!-- \"x3Cscript>';
  console.log(example);
</script>
<!-- this is just a comment between script blocks -->
<script>
  ... // this is a new script block
</script>
```

It is possible for these sequences to naturally occur in script expressions, as in the following examples:

```
if (x<!--y) { ... }
if ( player<script ) { ... }
```

In such cases the characters cannot be escaped, but the expressions can be rewritten so that the sequences don't occur, as in:

```
if (x < !--y) { ... }
if (!--y > x) { ... }
if (!(--y) > x) { ... }
if (player < script) { ... }
if (script > player) { ... }
```

Doing this also avoids a different pitfall as well: for related historical reasons, the string "<!--" in [classic scripts](#)<sup>p1085</sup> is actually treated as a line comment start, just like "/\*".

#### 4.12.1.4 Inline documentation for external scripts <sup>p66</sup><sub>8</sub>

If a [script](#)<sup>p652</sup> element's [src](#)<sup>p654</sup> attribute is specified, then the contents of the [script](#)<sup>p652</sup> element, if any, must be such that the value of the [text](#)<sup>p656</sup> IDL attribute, which is derived from the element's contents, matches the documentation production in the following ABNF, the character set for which is Unicode. [\[ABNF\]](#)<sup>p1475</sup>

```
documentation = *( *( space / tab / comment ) [ line-comment ] newline )
comment       = slash star *( not-star / star not-slash ) 1*star slash
line-comment  = slash slash *not-newline

; characters
tab           = %x0009 ; U+0009 CHARACTER TABULATION (tab)
newline      = %x000A ; U+000A LINE FEED (LF)
space        = %x0020 ; U+0020 SPACE
star         = %x002A ; U+002A ASTERISK (*)
slash        = %x002F ; U+002F SOLIDUS (/)
not-newline  = %x0000-0009 / %x000B-10FFFF
              ; a scalar_value other than U+000A LINE FEED (LF)
not-star     = %x0000-0029 / %x002B-10FFFF
              ; a scalar_value other than U+002A ASTERISK (*)
not-slash    = %x0000-002E / %x0030-10FFFF
              ; a scalar_value other than U+002F SOLIDUS (/)
```

#### Note

*This corresponds to putting the contents of the element in JavaScript comments.*

## Note

This requirement is in addition to the earlier restrictions on the syntax of contents of [script](#)<sup>p652</sup> elements.

## Example

This allows authors to include documentation, such as license information or API information, inside their documents while still referring to external script files. The syntax is constrained so that authors don't accidentally include what looks like valid script while also providing a [src](#)<sup>p654</sup> attribute.

```
<script src="cool-effects.js">
  // create new instances using:
  //   var e = new Effect();
  // start the effect using .play, stop using .stop:
  //   e.play();
  //   e.stop();
</script>
```

### 4.12.1.5 Interaction of [script](#)<sup>p652</sup> elements and XSLT <sup>p66</sup><sub>9</sub>

This section is non-normative.

This specification does not define how XSLT interacts with the [script](#)<sup>p652</sup> element. However, in the absence of another specification actually defining this, here are some guidelines for implementers, based on existing implementations:

- When an XSLT transformation program is triggered by an `<?xml-stylesheet?>` processing instruction and the browser implements a direct-to-DOM transformation, [script](#)<sup>p652</sup> elements created by the XSLT processor need to have its [parser document](#)<sup>p659</sup> set correctly, and run in document order (modulo scripts marked [defer](#)<sup>p654</sup> or [async](#)<sup>p654</sup>), [immediately](#)<sup>p43</sup>, as the transformation is occurring.
- The [XSLTProcessor](#)<sup>p51</sup> [transformToDocument\(\)](#)<sup>p51</sup> method adds elements to a [Document](#)<sup>p130</sup> object with a null [browsing context](#)<sup>p999</sup>, and, accordingly, any [script](#)<sup>p652</sup> elements they create need to have their [already started](#)<sup>p659</sup> set to true in the [prepare the script element](#)<sup>p661</sup> algorithm and never get executed ([scripting is disabled](#)<sup>p1083</sup>). Such [script](#)<sup>p652</sup> elements still need to have their [parser document](#)<sup>p659</sup> set, though, such that their [async](#)<sup>p656</sup> IDL attribute will return false in the absence of an [async](#)<sup>p654</sup> content attribute.
- The [XSLTProcessor](#)<sup>p51</sup> [transformToFragment\(\)](#)<sup>p51</sup> method needs to create a fragment that is equivalent to one built manually by creating the elements using [document.createElementNS\(\)](#). For instance, it needs to create [script](#)<sup>p652</sup> elements with null [parser document](#)<sup>p659</sup> and with their [already started](#)<sup>p659</sup> set to false, so that they will execute when the fragment is inserted into a document.

The main distinction between the first two cases and the last case is that the first two operate on [Document](#)<sup>p130</sup>s and the last operates on a fragment.

### 4.12.2 The [noscript](#) element <sup>p66</sup><sub>9</sub>

#### Categories<sup>p146</sup>:

[Metadata content](#)<sup>p148</sup>.  
[Flow content](#)<sup>p149</sup>.  
[Phrasing content](#)<sup>p150</sup>.

#### Contexts in which this element can be used<sup>p146</sup>:

In a [head](#)<sup>p173</sup> element of an [HTML document](#), if there are no ancestor [noscript](#)<sup>p669</sup> elements.  
Where [phrasing content](#)<sup>p150</sup> is expected in [HTML documents](#), if there are no ancestor [noscript](#)<sup>p669</sup> elements.

#### Content model<sup>p146</sup>:

When [scripting is disabled](#)<sup>p1083</sup>, in a [head](#)<sup>p173</sup> element: in any order, zero or more [link](#)<sup>p177</sup> elements, zero or more [style](#)<sup>p200</sup> elements, and zero or more [meta](#)<sup>p189</sup> elements.  
When [scripting is disabled](#)<sup>p1083</sup>, not in a [head](#)<sup>p173</sup> element: [transparent](#)<sup>p151</sup>, but there must be no [noscript](#)<sup>p669</sup> element descendants.

Otherwise: text that conforms to the requirements given in the prose.

**Tag omission in text/html<sup>p146</sup>:**

Neither tag is omissible.

**Content attributes<sup>p146</sup>:**

[Global attributes<sup>p154</sup>](#)

**Accessibility considerations<sup>p146</sup>:**

[For authors.](#)

[For implementers.](#)

**DOM interface<sup>p147</sup>:**

Uses [HTMLElement<sup>p142</sup>](#).

The [noscript<sup>p669</sup>](#) element [represents<sup>p141</sup>](#) nothing if [scripting is enabled<sup>p1083</sup>](#), and [represents<sup>p141</sup>](#) its children if [scripting is disabled<sup>p1083</sup>](#). It is used to present different markup to user agents that support scripting and those that don't support scripting, by affecting how the document is parsed.

When used in [HTML documents](#), the allowed content model is as follows:

**In a [head<sup>p173</sup>](#) element, if [scripting is disabled<sup>p1083</sup>](#) for the [noscript<sup>p669</sup>](#) element**

The [noscript<sup>p669</sup>](#) element must contain only [link<sup>p177</sup>](#), [style<sup>p200</sup>](#), and [meta<sup>p189</sup>](#) elements.

**In a [head<sup>p173</sup>](#) element, if [scripting is enabled<sup>p1083</sup>](#) for the [noscript<sup>p669</sup>](#) element**

The [noscript<sup>p669</sup>](#) element must contain only text, except that invoking the [HTML fragment parsing algorithm<sup>p1373</sup>](#) with the [noscript<sup>p669</sup>](#) element as the [context<sup>p1373</sup>](#) element and the text contents as the *input* must result in a list of nodes that consists only of [link<sup>p177</sup>](#), [style<sup>p200</sup>](#), and [meta<sup>p189</sup>](#) elements that would be conforming if they were children of the [noscript<sup>p669</sup>](#) element, and no [parse errors<sup>p1273</sup>](#).

**Outside of [head<sup>p173</sup>](#) elements, if [scripting is disabled<sup>p1083</sup>](#) for the [noscript<sup>p669</sup>](#) element**

The [noscript<sup>p669</sup>](#) element's content model is [transparent<sup>p151</sup>](#), with the additional restriction that a [noscript<sup>p669</sup>](#) element must not have a [noscript<sup>p669</sup>](#) element as an ancestor (that is, [noscript<sup>p669</sup>](#) can't be nested).

**Outside of [head<sup>p173</sup>](#) elements, if [scripting is enabled<sup>p1083</sup>](#) for the [noscript<sup>p669</sup>](#) element**

The [noscript<sup>p669</sup>](#) element must contain only text, except that the text must be such that running the following algorithm results in a conforming document with no [noscript<sup>p669</sup>](#) elements and no [script<sup>p652</sup>](#) elements, and such that no step in the algorithm throws an exception or causes an [HTML parser<sup>p1271</sup>](#) to flag a [parse error<sup>p1273</sup>](#):

1. Remove every [script<sup>p652</sup>](#) element from the document.
2. Make a list of every [noscript<sup>p669</sup>](#) element in the document. For every [noscript<sup>p669</sup>](#) element in that list, perform the following steps:
  1. Let *s* be the [child text content](#) of the [noscript<sup>p669</sup>](#) element.
  2. Set the [outerHTML<sup>p1159</sup>](#) attribute of the [noscript<sup>p669</sup>](#) element to the value of *s*. (This, as a side-effect, causes the [noscript<sup>p669</sup>](#) element to be removed from the document.)

**Note**

*All these contortions are required because, for historical reasons, the [noscript<sup>p669</sup>](#) element is handled differently by the [HTML parser<sup>p1271</sup>](#) based on whether [scripting was enabled or not<sup>p1289</sup>](#) when the parser was invoked.*

The [noscript<sup>p669</sup>](#) element must not be used in [XML documents](#).

**Note**

*The [noscript<sup>p669</sup>](#) element is only effective in [the HTML syntax<sup>p1259</sup>](#), it has no effect in [the XML syntax<sup>p1384</sup>](#). This is because the way it works is by essentially "turning off" the parser when scripts are enabled, so that the contents of the element are treated as pure text and not as real elements. XML does not define a mechanism by which to do this.*

The [noscript<sup>p669</sup>](#) element has no other requirements. In particular, children of the [noscript<sup>p669</sup>](#) element are not exempt from [form submission<sup>p628</sup>](#), scripting, and so forth, even when [scripting is enabled<sup>p1083</sup>](#) for the element.

## Example

In the following example, a [noscript](#)<sup>p669</sup> element is used to provide fallback for a script.

```
<form action="calcSquare.php">
  <p>
    <label for=x>Number</label>:
    <input id="x" name="x" type="number">
  </p>
  <script>
    var x = document.getElementById('x');
    var output = document.createElement('p');
    output.textContent = 'Type a number; it will be squared right then!';
    x.form.appendChild(output);
    x.form.onsubmit = function () { return false; }
    x.oninput = function () {
      var v = x.valueAsNumber;
      output.textContent = v + ' squared is ' + v * v;
    };
  </script>
  <noscript>
    <input type=submit value="Calculate Square">
  </noscript>
</form>
```

When script is disabled, a button appears to do the calculation on the server side. When script is enabled, the value is computed on-the-fly instead.

The [noscript](#)<sup>p669</sup> element is a blunt instrument. Sometimes, scripts might be enabled, but for some reason the page's script might fail. For this reason, it's generally better to avoid using [noscript](#)<sup>p669</sup>, and to instead design the script to change the page from being a scriptless page to a scripted page on the fly, as in the next example:

```
<form action="calcSquare.php">
  <p>
    <label for=x>Number</label>:
    <input id="x" name="x" type="number">
  </p>
  <input id="submit" type=submit value="Calculate Square">
  <script>
    var x = document.getElementById('x');
    var output = document.createElement('p');
    output.textContent = 'Type a number; it will be squared right then!';
    x.form.appendChild(output);
    x.form.onsubmit = function () { return false; }
    x.oninput = function () {
      var v = x.valueAsNumber;
      output.textContent = v + ' squared is ' + v * v;
    };
    var submit = document.getElementById('submit');
    submit.parentNode.removeChild(submit);
  </script>
</form>
```

The above technique is also useful in [XML documents](#), since [noscript](#)<sup>p669</sup> is not allowed there.

### 4.12.3 The **template** element <sup>p67</sup><sub>1</sub>

Categories<sup>p146</sup>:

[Metadata content](#)<sup>p148</sup>.  
[Flow content](#)<sup>p149</sup>.

✓ MDN

✓ MDN

[Phrasing content](#)<sup>p150</sup>.  
[Script-supporting element](#)<sup>p151</sup>.

#### Contexts in which this element can be used<sup>p146</sup>:

Where [metadata content](#)<sup>p148</sup> is expected.  
Where [phrasing content](#)<sup>p150</sup> is expected.  
Where [script-supporting elements](#)<sup>p151</sup> are expected.  
As a child of a [colgroup](#)<sup>p487</sup> element that doesn't have a [span](#)<sup>p488</sup> attribute.

#### Content model<sup>p146</sup>:

[Nothing](#)<sup>p148</sup> (for clarification, [see example](#)<sup>p673</sup>).

#### Tag omission in text/html<sup>p146</sup>:

Neither tag is omissible.

#### Content attributes<sup>p146</sup>:

[Global attributes](#)<sup>p154</sup>  
[shadowrootmode](#)<sup>p672</sup> — Enables streaming declarative shadow roots  
[shadowrootdelegatesfocus](#)<sup>p672</sup> — Sets [delegates focus](#) on a declarative shadow root  
[shadowrootclonable](#)<sup>p672</sup> — Sets [clonable](#) on a declarative shadow root  
[shadowrootserializable](#)<sup>p672</sup> — Sets [serializable](#)<sup>p117</sup> on a declarative shadow root

#### Accessibility considerations<sup>p146</sup>:

[For authors](#).  
[For implementers](#).

#### DOM interface<sup>p147</sup>:

```
IDL [Exposed=Window]
interface HTMLTemplateElement : HTMLFElement {
    [HTMLConstructor] constructor();

    readonly attribute DocumentFragment content;
    [CEReactions] attribute DOMString shadowRootMode;
    [CEReactions] attribute boolean shadowRootDelegatesFocus;
    [CEReactions] attribute boolean shadowRootClonable;
    [CEReactions] attribute boolean shadowRootSerializable;
};
```

The [template](#)<sup>p671</sup> element is used to declare fragments of HTML that can be cloned and inserted in the document by script.

In a rendering, the [template](#)<sup>p671</sup> element [represents](#)<sup>p141</sup> nothing.

The [shadowrootmode](#) content attribute is an [enumerated attribute](#)<sup>p76</sup> with the following keywords and states:

Keyword	State	Brief description
<b>open</b>	<b>open</b>	The template element represents an open declarative shadow root.
<b>closed</b>	<b>closed</b>	The template element represents a closed declarative shadow root.

The [shadowrootmode](#)<sup>p672</sup> attribute's [invalid value default](#)<sup>p76</sup> and [missing value default](#)<sup>p76</sup> are both the **none** state.

The [shadowrootdelegatesfocus](#) content attribute is a [boolean attribute](#)<sup>p75</sup>.

The [shadowrootclonable](#) content attribute is a [boolean attribute](#)<sup>p75</sup>.

The [shadowrootserializable](#) content attribute is a [boolean attribute](#)<sup>p75</sup>.

The [template contents](#)<sup>p673</sup> of a [template](#)<sup>p671</sup> element [are not children of the element itself](#)<sup>p1261</sup>.

#### Note

*It is also possible, as a result of DOM manipulation, for a [template](#)<sup>p671</sup> element to contain **Text** nodes and element nodes; however, having any is a violation of the [template](#)<sup>p671</sup> element's content model, since its content model is defined as [nothing](#)<sup>p148</sup>.*

## Example

For example, consider the following document:

```
<!doctype html>
<html lang="en">
  <head>
    <title>Homework</title>
  <body>
    <template id="template"><p>Smile!</p></template>
    <script>
      let num = 3;
      const fragment = document.getElementById('template').content.cloneNode(true);
      while (num-- > 1) {
        fragment.firstChild.before(fragment.firstChild.cloneNode(true));
        fragment.firstChild.textContent += fragment.lastChild.textContent;
      }
      document.body.appendChild(fragment);
    </script>
  </body>
</html>
```

The [p<sup>p229</sup>](#) element in the [template<sup>p671</sup>](#) is *not* a child of the [template<sup>p671</sup>](#) in the DOM; it is a child of the [DocumentFragment](#) returned by the [template<sup>p671</sup>](#) element's [content<sup>p674</sup>](#) IDL attribute.

If the script were to call [appendChild\(\)](#) on the [template<sup>p671</sup>](#) element, that would add a child to the [template<sup>p671</sup>](#) element (as for any other element); however, doing so is a violation of the [template<sup>p671</sup>](#) element's content model.

## For web developers (non-normative)

### [template.content<sup>p674</sup>](#)

Returns the [template contents<sup>p673</sup>](#) (a [DocumentFragment](#)).

Each [template<sup>p671</sup>](#) element has an associated [DocumentFragment](#) object that is its **template contents**. The [template contents<sup>p673</sup>](#) have [no conformance requirements<sup>p140</sup>](#). When a [template<sup>p671</sup>](#) element is created, the user agent must run the following steps to establish the [template contents<sup>p673</sup>](#):

1. Let *doc* be the [template<sup>p671</sup>](#) element's [node document](#)'s [appropriate template contents owner document<sup>p673</sup>](#).
2. Create a [DocumentFragment](#) object whose [node document](#) is *doc* and [host](#) is the [template<sup>p671</sup>](#) element.
3. Set the [template<sup>p671</sup>](#) element's [template contents<sup>p673</sup>](#) to the newly created [DocumentFragment](#) object.

A [Document<sup>p130</sup>](#) *doc*'s **appropriate template contents owner document** is the [Document<sup>p130</sup>](#) returned by the following algorithm:

1. If *doc* is not a [Document<sup>p130</sup>](#) created by this algorithm, then:
  1. If *doc* does not yet have an **associated inert template document**, then:
    1. Let *new doc* be a new [Document<sup>p130</sup>](#) (whose [browsing context<sup>p999</sup>](#) is null). This is "a [Document<sup>p130</sup>](#) created by this algorithm" for the purposes of the step above.
    2. If *doc* is an [HTML document](#), mark *new doc* as an [HTML document](#) also.
    3. Let *doc*'s [associated inert template document<sup>p673</sup>](#) be *new doc*.
  2. Set *doc* to *doc*'s [associated inert template document<sup>p673</sup>](#).

## Note

Each [Document<sup>p130</sup>](#) not created by this algorithm thus gets a single [Document<sup>p130</sup>](#) to act as its proxy for owning the [template contents<sup>p673</sup>](#) of all its [template<sup>p671</sup>](#) elements, so that they aren't in a [browsing context<sup>p998</sup>](#) and thus remain inert (e.g. scripts do not run). Meanwhile, [template<sup>p671</sup>](#) elements inside [Document<sup>p130</sup>](#) objects that are created by this algorithm just reuse the same [Document<sup>p130</sup>](#) owner for their contents.

2. Return *doc*.

The [adopting\\_steps](#) (with *node* and *oldDocument* as parameters) for [template](#)<sup>p671</sup> elements are the following:

1. Let *doc* be *node*'s [node document](#)'s [appropriate template contents owner document](#)<sup>p673</sup>.

**Note**

*node*'s [node document](#) is the [Document](#)<sup>p130</sup> object that *node* was just adopted into.

2. Adopt *node*'s [template contents](#)<sup>p673</sup> (a [DocumentFragment](#) object) into *doc*.

The **content** getter steps are to return [template](#)<sup>p671</sup>'s [template contents](#)<sup>p673</sup>, if the [template contents](#)<sup>p673</sup> is not a [ShadowRoot](#) node; otherwise null.

The **shadowRootMode** IDL attribute must [reflect](#)<sup>p104</sup> the [shadowrootmode](#)<sup>p672</sup> content attribute, [limited to only known values](#)<sup>p105</sup>.

The **shadowRootDelegatesFocus** IDL attribute must [reflect](#)<sup>p104</sup> the [shadowrootdelegatesfocus](#)<sup>p672</sup> content attribute.

The **shadowRootClonable** IDL attribute must [reflect](#)<sup>p104</sup> the [shadowrootclonable](#)<sup>p672</sup> content attribute.

The **shadowRootSerializable** IDL attribute must [reflect](#)<sup>p104</sup> the [shadowrootserializable](#)<sup>p672</sup> content attribute.

The [cloning\\_steps](#) for a [template](#)<sup>p671</sup> element *node* being cloned to a copy *copy* must run the following steps:

1. If the *clone children flag* is not set in the calling [clone](#) algorithm, return.
2. Let *copied contents* be the result of [cloning](#) all the children of *node*'s [template contents](#)<sup>p673</sup>, with *document* set to *copy*'s [template contents](#)<sup>p673</sup>'s [node document](#), and with the *clone children flag* set.
3. Append *copied contents* to *copy*'s [template contents](#)<sup>p673</sup>.

**Example**

In this example, a script populates a table four-column with data from a data structure, using a [template](#)<sup>p671</sup> to provide the element structure instead of manually generating the structure from markup.

```
<!DOCTYPE html>
<html lang='en'>
<title>Cat data</title>
<script>
  // Data is hard-coded here, but could come from the server
  var data = [
    { name: 'Pillar', color: 'Ticked Tabby', sex: 'Female (neutered)', legs: 3 },
    { name: 'Hedral', color: 'Tuxedo', sex: 'Male (neutered)', legs: 4 },
  ];
</script>
<table>
  <thead>
    <tr>
      <th>Name <th>Color <th>Sex <th>Legs
  <tbody>
    <template id="row">
      <tr><td><td><td><td>
    </template>
  </table>
<script>
  var template = document.querySelector('#row');
  for (var i = 0; i < data.length; i += 1) {
    var cat = data[i];
    var clone = template.content.cloneNode(true);
    var cells = clone.querySelectorAll('td');
    cells[0].textContent = cat.name;
    cells[1].textContent = cat.color;
    cells[2].textContent = cat.sex;
```

```

    cells[3].textContent = cat.legs;
    template.parentNode.appendChild(clone);
}
</script>

```

This example uses `cloneNode()` on the [template](#)<sup>p671</sup>'s contents; it could equivalently have used `document.importNode()`, which does the same thing. The only difference between these two APIs is when the [node document](#) is updated: with `cloneNode()` it is updated when the nodes are appended with `appendChild()`, with `document.importNode()` it is updated when the nodes are cloned.

#### 4.12.3.1 Interaction of [template](#)<sup>p671</sup> elements with XSLT and XPath §<sup>p67</sup>5

*This section is non-normative.*

This specification does not define how XSLT and XPath interact with the [template](#)<sup>p671</sup> element. However, in the absence of another specification actually defining this, here are some guidelines for implementers, which are intended to be consistent with other processing described in this specification:

- An XSLT processor based on an XML parser that acts [as described in this specification](#)<sup>p1384</sup> needs to act as if [template](#)<sup>p671</sup> elements contain as descendants their [template contents](#)<sup>p673</sup> for the purposes of the transform.
- An XSLT processor that outputs a DOM needs to ensure that nodes that would go into a [template](#)<sup>p671</sup> element are instead placed into the element's [template contents](#)<sup>p673</sup>.
- XPath evaluation using the XPath DOM API when applied to a [Document](#)<sup>p130</sup> parsed using the [HTML parser](#)<sup>p1271</sup> or the [XML parser](#)<sup>p1384</sup> described in this specification needs to ignore [template contents](#)<sup>p673</sup>.

#### 4.12.4 The [slot](#) element §<sup>p67</sup>5

##### Categories<sup>p146</sup>:

[Flow content](#)<sup>p149</sup>.  
[Phrasing content](#)<sup>p150</sup>.

##### Contexts in which this element can be used<sup>p146</sup>:

Where [phrasing content](#)<sup>p150</sup> is expected.

##### Content model<sup>p146</sup>:

[Transparent](#)<sup>p151</sup>

##### Tag omission in text/html<sup>p146</sup>:

Neither tag is omissible.

##### Content attributes<sup>p146</sup>:

[Global attributes](#)<sup>p154</sup>  
[name](#)<sup>p676</sup> — Name of shadow tree slot

##### Accessibility considerations<sup>p146</sup>:

[For authors](#).  
[For implementers](#).

##### DOM interface<sup>p147</sup>:

```

IDL [Exposed=Window]
interface HTMLSlotElement : HTMLElement {
    [HTMLConstructor] constructor();

    [CEReactions] attribute DOMString name;
    sequence<Node> assignedNodes(optional AssignedNodesOptions options = {});

```

```
sequence<Element> assignedElements(optional AssignedNodesOptions options = {});
undefined assign((Element or Text)... nodes);
};

dictionary AssignedNodesOptions {
    boolean flatten = false;
};
```

The [slot<sup>p675</sup>](#) element defines a [slot](#). It is typically used in a [shadow tree](#). A [slot<sup>p675</sup>](#) element [represents<sup>p141</sup>](#) its [assigned nodes](#), if any, and its contents otherwise.

The **name** content attribute may contain any string value. It represents a [slot's name](#).

#### Note

The [name<sup>p676</sup>](#) attribute is used to [assign slots](#) to other elements: a [slot<sup>p675</sup>](#) element with a [name<sup>p676</sup>](#) attribute creates a named [slot](#) to which any element is [assigned](#) if that element has a [slot<sup>p154</sup>](#) attribute whose value matches that [name<sup>p676</sup>](#) attribute's value, and the [slot<sup>p675</sup>](#) element is a child of the [shadow tree](#) whose [root's host](#) has that corresponding [slot<sup>p154</sup>](#) attribute value.

#### For web developers (non-normative)

##### [slot.name<sup>p676</sup>](#)

Can be used to get and set [slot's name](#).

##### [slot.assignedNodes<sup>p676</sup>\(\)](#)

Returns [slot's assigned nodes](#).

##### [slot.assignedNodes<sup>p676</sup>\({ flatten: true }\)](#)

Returns [slot's assigned nodes](#), if any, and [slot's children](#) otherwise, and does the same for any [slot<sup>p675</sup>](#) elements encountered therein, recursively, until there are no [slot<sup>p675</sup>](#) elements left.

##### [slot.assignedElements<sup>p676</sup>\(\)](#)

Returns [slot's assigned nodes](#), limited to elements.

##### [slot.assignedElements<sup>p676</sup>\({ flatten: true }\)](#)

Returns the same as [assignedNodes\({ flatten: true }\)<sup>p676</sup>](#), limited to elements.

##### [slot.assign<sup>p676</sup>\(...nodes\)](#)

Sets [slot's manually assigned nodes<sup>p676</sup>](#) to the given [nodes](#).

The **name** IDL attribute must [reflect<sup>p104</sup>](#) the content attribute of the same name.

The [slot<sup>p675</sup>](#) element has **manually assigned nodes**, which is an [ordered set](#) of [slottables](#) set by [assign\(\)<sup>p676</sup>](#). This set is initially empty.

#### Note

The [manually assigned nodes<sup>p676</sup>](#) set can be implemented using weak references to the [slottables](#), because this set is not directly accessible from script.

The [assignedNodes\(options\)](#) method steps are:

1. If [options\["flatten<sup>p676</sup>"\]](#) is false, then return [this's assigned nodes](#).
2. Return the result of [finding flattened slottables](#) with [this](#).

The [assignedElements\(options\)](#) method steps are:

1. If [options\["flatten<sup>p676</sup>"\]](#) is false, then return [this's assigned nodes](#), filtered to contain only [Element](#) nodes.
2. Return the result of [finding flattened slottables](#) with [this](#), filtered to contain only [Element](#) nodes.

The [assign\(...nodes\)](#) method steps are:

1. For each [node](#) of [this's manually assigned nodes<sup>p676</sup>](#), set [node's manual slot assignment](#) to null.

2. Let *nodesSet* be a new [ordered set](#).
3. [For each](#) *node* of *nodes*:
  1. If *node*'s [manual slot assignment](#) refers to a [slot](#)<sup>p675</sup>, then remove *node* from that [slot](#)<sup>p675</sup>'s [manually assigned nodes](#)<sup>p676</sup>.
  2. Set *node*'s [manual slot assignment](#) to [this](#).
  3. [Append](#) *node* to *nodesSet*.
4. Set [this](#)'s [manually assigned nodes](#)<sup>p676</sup> to *nodesSet*.
5. Run [assign slottables for a tree](#) for [this](#)'s [root](#).

#### 4.12.5 The **canvas** element <sup>p67</sup><sub>7</sub>

##### Categories<sup>p146</sup>:

[Flow content](#)<sup>p149</sup>.  
[Phrasing content](#)<sup>p150</sup>.  
[Embedded content](#)<sup>p150</sup>.  
[Palpable content](#)<sup>p150</sup>.

##### Contexts in which this element can be used<sup>p146</sup>:

Where [embedded content](#)<sup>p150</sup> is expected.

##### Content model<sup>p146</sup>:

[Transparent](#)<sup>p151</sup>, but with no [interactive content](#)<sup>p150</sup> descendants except for [a](#)<sup>p257</sup> elements, [img](#)<sup>p346</sup> elements with [usemap](#)<sup>p473</sup> attributes, [button](#)<sup>p566</sup> elements, [input](#)<sup>p520</sup> elements whose [type](#)<sup>p523</sup> attribute are in the [Checkbox](#)<sup>p542</sup> or [Radio Button](#)<sup>p543</sup> states, [input](#)<sup>p520</sup> elements that are [buttons](#)<sup>p514</sup>, and [select](#)<sup>p568</sup> elements with a [multiple](#)<sup>p569</sup> attribute or a [display size](#)<sup>p569</sup> greater than 1.

##### Tag omission in text/html<sup>p146</sup>:

Neither tag is omissible.

##### Content attributes<sup>p146</sup>:

[Global attributes](#)<sup>p154</sup>  
[width](#)<sup>p678</sup> — Horizontal dimension  
[height](#)<sup>p678</sup> — Vertical dimension

##### Accessibility considerations<sup>p146</sup>:

[For authors](#).  
[For implementers](#).

##### DOM interface<sup>p147</sup>:

```

IDL
typedef (CanvasRenderingContext2D or ImageBitmapRenderingContext or WebGLRenderingContext or
WebGL2RenderingContext or GPUCanvasContext) RenderingContext;

[Exposed=Window]
interface HTMLCanvasElement : HTMLElement {
    [HTMLConstructor] constructor();

    [CEReactions] attribute unsigned long width;
    [CEReactions] attribute unsigned long height;

    RenderingContext? getContext(DOMString contextId, optional any options = null);

    USVString toDataURL(optional DOMString type = "image/png", optional any quality);
    undefined toBlob(BlobCallback _callback, optional DOMString type = "image/png", optional any
quality);
    OffscreenCanvas transferControlToOffscreen();
};
  
```

```
callback BlobCallback = undefined (Blob? blob);
```

The [canvas](#)<sup>p677</sup> element provides scripts with a resolution-dependent bitmap canvas, which can be used for rendering graphs, game graphics, art, or other visual images on the fly.

Authors should not use the [canvas](#)<sup>p677</sup> element in a document when a more suitable element is available. For example, it is inappropriate to use a [canvas](#)<sup>p677</sup> element to render a page heading: if the desired presentation of the heading is graphically intense, it should be marked up using appropriate elements (typically [h1](#)<sup>p216</sup>) and then styled using CSS and supporting technologies such as [shadow trees](#).

When authors use the [canvas](#)<sup>p677</sup> element, they must also provide content that, when presented to the user, conveys essentially the same function or purpose as the [canvas](#)<sup>p677</sup>'s bitmap. This content may be placed as content of the [canvas](#)<sup>p677</sup> element. The contents of the [canvas](#)<sup>p677</sup> element, if any, are the element's [fallback content](#)<sup>p150</sup>.

In interactive visual media, if [scripting is enabled](#)<sup>p1083</sup> for the [canvas](#)<sup>p677</sup> element, and if support for [canvas](#)<sup>p677</sup> elements has been enabled, then the [canvas](#)<sup>p677</sup> element [represents](#)<sup>p141</sup> [embedded content](#)<sup>p150</sup> consisting of a dynamically created image, the element's bitmap.

In non-interactive, static, visual media, if the [canvas](#)<sup>p677</sup> element has been previously associated with a rendering context (e.g. if the page was viewed in an interactive visual medium and is now being printed, or if some script that ran during the page layout process painted on the element), then the [canvas](#)<sup>p677</sup> element [represents](#)<sup>p141</sup> [embedded content](#)<sup>p150</sup> with the element's current bitmap and size. Otherwise, the element represents its [fallback content](#)<sup>p150</sup> instead.

In non-visual media, and in visual media if [scripting is disabled](#)<sup>p1083</sup> for the [canvas](#)<sup>p677</sup> element or if support for [canvas](#)<sup>p677</sup> elements has been disabled, the [canvas](#)<sup>p677</sup> element [represents](#)<sup>p141</sup> its [fallback content](#)<sup>p150</sup> instead.

When a [canvas](#)<sup>p677</sup> element [represents](#)<sup>p141</sup> [embedded content](#)<sup>p150</sup>, the user can still focus descendants of the [canvas](#)<sup>p677</sup> element (in the [fallback content](#)<sup>p150</sup>). When an element is [focused](#)<sup>p836</sup>, it is the target of keyboard interaction events (even though the element itself is not visible). This allows authors to make an interactive canvas keyboard-accessible: authors should have a one-to-one mapping of interactive regions to [focusable areas](#)<sup>p835</sup> in the [fallback content](#)<sup>p150</sup>. (Focus has no effect on mouse interaction events.) [\[UIEVENTS\]](#)<sup>p1483</sup>

An element whose nearest [canvas](#)<sup>p677</sup> element ancestor is [being rendered](#)<sup>p1388</sup> and [represents](#)<sup>p141</sup> [embedded content](#)<sup>p150</sup> is an element that is **being used as relevant canvas fallback content**.

The [canvas](#)<sup>p677</sup> element has two attributes to control the size of the element's bitmap: **width** and **height**. These attributes, when specified, must have values that are [valid non-negative integers](#)<sup>p77</sup>. The [rules for parsing non-negative integers](#)<sup>p77</sup> must be used to **obtain their numeric values**. If an attribute is missing, or if parsing its value returns an error, then the default value must be used instead. The [width](#)<sup>p678</sup> attribute defaults to 300, and the [height](#)<sup>p678</sup> attribute defaults to 150.

When setting the value of the [width](#)<sup>p678</sup> or [height](#)<sup>p678</sup> attribute, if the [context mode](#)<sup>p679</sup> of the [canvas](#)<sup>p677</sup> element is set to [placeholder](#)<sup>p679</sup>, the user agent must throw an ["InvalidStateError" DOMException](#) and leave the attribute's value unchanged.

The [natural dimensions](#) of the [canvas](#)<sup>p677</sup> element when it [represents](#)<sup>p141</sup> [embedded content](#)<sup>p150</sup> are equal to the dimensions of the element's bitmap.

The user agent must use a square pixel density consisting of one pixel of image data per coordinate space unit for the bitmaps of a [canvas](#)<sup>p677</sup> and its rendering contexts.

#### Note

A [canvas](#)<sup>p677</sup> element can be sized arbitrarily by a style sheet, its bitmap is then subject to the ['object-fit'](#) CSS property.

The bitmaps of [canvas](#)<sup>p677</sup> elements, the bitmaps of [ImageBitmap](#)<sup>p1181</sup> objects, as well as some of the bitmaps of rendering contexts, such as those described in the sections on the [CanvasRenderingContext2D](#)<sup>p682</sup> and [ImageBitmapRenderingContext](#)<sup>p739</sup> objects below, have an **origin-clean** flag, which can be set to true or false. Initially, when the [canvas](#)<sup>p677</sup> element or [ImageBitmap](#)<sup>p1181</sup> object is created, its bitmap's [origin-clean](#)<sup>p678</sup> flag must be set to true.

A [canvas](#)<sup>p677</sup> element can have a rendering context bound to it. Initially, it does not have a bound rendering context. To keep track of

whether it has a rendering context or not, and what kind of rendering context it is, a [canvas](#)<sup>p677</sup> also has a **canvas context mode**, which is initially **none** but can be changed to either **placeholder**, **2d**, **bitmaprenderer**, **webgl**, **webgl2**, or **webgpu** by algorithms defined in this specification.

When its [canvas context mode](#)<sup>p679</sup> is [none](#)<sup>p679</sup>, a [canvas](#)<sup>p677</sup> element has no rendering context, and its bitmap must be [transparent black](#) with a [natural width](#) equal to [the numeric value](#)<sup>p678</sup> of the element's [width](#)<sup>p678</sup> attribute and a [natural height](#) equal to [the numeric value](#)<sup>p678</sup> of the element's [height](#)<sup>p678</sup> attribute, those values being interpreted in [CSS pixels](#), and being updated as the attributes are set, changed, or removed.

When its [canvas context mode](#)<sup>p679</sup> is [placeholder](#)<sup>p679</sup>, a [canvas](#)<sup>p677</sup> element has no rendering context. It serves as a placeholder for an [OffscreenCanvas](#)<sup>p741</sup> object, and the content of the [canvas](#)<sup>p677</sup> element is updated by the [OffscreenCanvas](#)<sup>p741</sup> object's rendering context.

When a [canvas](#)<sup>p677</sup> element represents [embedded content](#)<sup>p150</sup>, it provides a [paint source](#) whose width is the element's [natural width](#), whose height is the element's [natural height](#), and whose appearance is the element's bitmap.

Whenever the [width](#)<sup>p678</sup> and [height](#)<sup>p678</sup> content attributes are set, removed, changed, or redundantly set to the value they already have, then the user agent must perform the action from the row of the following table that corresponds to the [canvas](#)<sup>p677</sup> element's [context mode](#)<sup>p679</sup>.

<a href="#">Context Mode</a> <sup>p679</sup>	Action
<a href="#">2d</a> <sup>p679</sup>	Follow the steps to <a href="#">set bitmap dimensions</a> <sup>p688</sup> to <a href="#">the numeric values</a> <sup>p678</sup> of the <a href="#">width</a> <sup>p678</sup> and <a href="#">height</a> <sup>p678</sup> content attributes.
<a href="#">webgl</a> <sup>p679</sup> or <a href="#">webgl2</a> <sup>p679</sup>	Follow the behavior defined in the WebGL specifications. <a href="#">[WEBGL]</a> <sup>p1483</sup>
<a href="#">webgpu</a> <sup>p679</sup>	Follow the behavior defined in <i>WebGPU</i> . <a href="#">[WEBGPU]</a> <sup>p1483</sup>
<a href="#">bitmaprenderer</a> <sup>p679</sup>	If the context's <a href="#">bitmap mode</a> <sup>p740</sup> is set to <a href="#">blank</a> <sup>p740</sup> , run the steps to <a href="#">set an ImageBitmapRenderingContext's output bitmap</a> <sup>p740</sup> , passing the <a href="#">canvas</a> <sup>p677</sup> element's rendering context.
<a href="#">placeholder</a> <sup>p679</sup>	Do nothing.
<a href="#">none</a> <sup>p679</sup>	Do nothing.

The [width](#) and [height](#) IDL attributes must [reflect](#)<sup>p104</sup> the respective content attributes of the same name, with the same defaults. MIDN

For web developers (non-normative)

```
context = canvas.getContextp679(contextId [, options ])
```

Returns an object that exposes an API for drawing on the canvas. *contextId* specifies the desired API: "[2d](#)<sup>p688</sup>", "[bitmaprenderer](#)<sup>p688</sup>", "[webgl](#)<sup>p688</sup>", "[webgl2](#)<sup>p688</sup>", or "[webgpu](#)<sup>p688</sup>". *options* is handled by that API.

This specification defines the "[2d](#)<sup>p688</sup>" and "[bitmaprenderer](#)<sup>p688</sup>" contexts below. The WebGL specifications define the "[webgl](#)<sup>p688</sup>" and "[webgl2](#)<sup>p688</sup>" contexts. *WebGPU* defines the "[webgpu](#)<sup>p688</sup>" context. [\[WEBGL\]](#)<sup>p1483</sup> [\[WEBGPU\]](#)<sup>p1483</sup>

Returns null if *contextId* is not supported, or if the canvas has already been initialized with another context type (e.g., trying to get a "[2d](#)<sup>p688</sup>" context after getting a "[webgl](#)<sup>p688</sup>" context).

The [getContext\(contextId, options\)](#) method of the [canvas](#)<sup>p677</sup> element, when invoked, must run these steps:

- If *options* is not an [object](#), then set *options* to null.
- Set *options* to the result of [converting options](#) to a JavaScript value.
- Run the steps in the cell of the following table whose column header matches this [canvas](#)<sup>p677</sup> element's [canvas context mode](#)<sup>p679</sup> and whose row header matches *contextId*:

	<a href="#">none</a> <sup>p679</sup>	<a href="#">2d</a> <sup>p679</sup>	<a href="#">bitmaprenderer</a> <sup>p679</sup>	<a href="#">webgl</a> <sup>p679</sup> or <a href="#">webgl2</a> <sup>p679</sup>	<a href="#">webgpu</a> <sup>p679</sup>	<a href="#">placeholder</a> <sup>p679</sup>
"2d"	<ol style="list-style-type: none"> <li>Let <i>context</i> be the result of running the <a href="#">2D context creation algorithm</a><sup>p688</sup> given <i>this</i> and <i>options</i>.</li> <li>Set <i>this</i>'s <a href="#">context mode</a><sup>p679</sup> to <a href="#">2d</a><sup>p679</sup>.</li> <li>Return <i>context</i>.</li> </ol>	Return the same object as was returned the last time the method was invoked with this same first argument.	Return null.	Return null.	Return null.	Throw an <a href="#">"InvalidStateError"</a> <sup>p679</sup> <a href="#">DOMException</a> .
"bitmaprenderer"	<ol style="list-style-type: none"> <li>Let <i>context</i> be the result of running the <a href="#">ImageBitmapRenderingContext creation algorithm</a><sup>p741</sup> given <i>this</i> and <i>options</i>.</li> <li>Set <i>this</i>'s <a href="#">context mode</a><sup>p679</sup> to <a href="#">bitmaprenderer</a><sup>p679</sup>.</li> <li>Return <i>context</i>.</li> </ol>	Return null.	Return the same object as was returned the last time the method was invoked with this same first argument.	Return null.	Return null.	Throw an <a href="#">"InvalidStateError"</a> <sup>p679</sup> <a href="#">DOMException</a> .
"webgl" or "webgl2", if the user agent supports the WebGL feature in its current configuration	<ol style="list-style-type: none"> <li>Let <i>context</i> be the result of following the instructions given in the WebGL specifications' <a href="#">Context Creation</a> sections. <a href="#">[WEBGL]</a><sup>p1483</sup></li> <li>If <i>context</i> is null, then return null; otherwise set <i>this</i>'s <a href="#">context mode</a><sup>p679</sup> to <a href="#">webgl</a><sup>p679</sup> or <a href="#">webgl2</a><sup>p679</sup>.</li> <li>Return <i>context</i>.</li> </ol>	Return null.	Return null.	Return the same object as was returned the last time the method was invoked with this same first argument.	Return null.	Throw an <a href="#">"InvalidStateError"</a> <sup>p679</sup> <a href="#">DOMException</a> .
"webgpu", if the user agent supports the WebGPU feature in its current configuration	<ol style="list-style-type: none"> <li>Let <i>context</i> be the result of following the instructions given in WebGPU's <a href="#">Canvas Rendering</a> section. <a href="#">[WEBGPU]</a><sup>p1483</sup></li> <li>If <i>context</i> is null, then return null; otherwise set <i>this</i>'s <a href="#">context mode</a><sup>p679</sup> to <a href="#">webgpu</a><sup>p679</sup>.</li> <li>Return <i>context</i>.</li> </ol>	Return null.	Return null.	Return null.	Return the same object as was returned the last time the method was invoked with this same first argument.	Throw an <a href="#">"InvalidStateError"</a> <sup>p679</sup> <a href="#">DOMException</a> .
An unsupported value*	Return null.	Return null.	Return null.	Return null.	Return null.	Throw an <a href="#">"InvalidStateError"</a> <sup>p679</sup> <a href="#">DOMException</a> .

\* For example, the "[webgl](#)<sup>p680</sup>" or "[webgl2](#)<sup>p680</sup>" value in the case of a user agent having exhausted the graphics hardware's abilities and having no software fallback implementation.

#### For web developers (non-normative)

`url = canvas.toDataURLp681([ type [, quality ] ])`

Returns a [data: URL](#) for the image in the canvas.

The first argument, if provided, controls the type of the image to be returned (e.g. PNG or JPEG). The default is "[image/png](#)<sup>p1473</sup>"; that type is also used if the given type isn't supported. The second argument applies if the type is an image format that supports variable quality (such as "[image/jpeg](#)<sup>p1473</sup>"), and is a number in the range 0.0 to 1.0 inclusive indicating the desired quality level for the resulting image.

When trying to use types other than "[image/png](#)<sup>p1473</sup>", authors can check if the image was really returned in the requested format by checking to see if the returned string starts with one of the exact strings "data:image/png," or "data:image/png;".

If it does, the image is PNG, and thus the requested type was not supported. (The one exception to this is if the canvas has either no height or no width, in which case the result might simply be "data: ,".)

**`canvas.toBlob`**<sup>p681</sup>(*callback* [, *type* [, *quality* ] ])

Creates a **Blob** object representing a file containing the image in the canvas, and invokes a callback with a handle to that object.

The second argument, if provided, controls the type of the image to be returned (e.g. PNG or JPEG). The default is "**image/png**"<sup>p1473</sup>; that type is also used if the given type isn't supported. The third argument applies if the type is an image format that supports variable quality (such as "**image/jpeg**"<sup>p1473</sup>"), and is a number in the range 0.0 to 1.0 inclusive indicating the desired quality level for the resulting image.

**`canvas.transferControlToOffscreen`**<sup>p681</sup>()

Returns a newly created **OffscreenCanvas**<sup>p741</sup> object that uses the **canvas**<sup>p677</sup> element as a placeholder. Once the **canvas**<sup>p677</sup> element has become a placeholder for an **OffscreenCanvas**<sup>p741</sup> object, its natural size can no longer be changed, and it cannot have a rendering context. The content of the placeholder canvas is updated on the **OffscreenCanvas**<sup>p741</sup>'s **relevant agent**<sup>p1073</sup>'s **event loop**<sup>p1123</sup>'s **update the rendering**<sup>p1128</sup> steps.

The **`toDataURL`**(*type*, *quality*) method, when invoked, must run these steps:

1. If this **canvas**<sup>p677</sup> element's **origin-clean**<sup>p678</sup> flag is set to false, then throw a "**SecurityError**" **DOMException**.
2. If this **canvas**<sup>p677</sup> element's bitmap has no pixels (i.e. either its horizontal dimension or its vertical dimension is zero) then return the string "data: ,". (This is the shortest **data: URL**; it represents the empty string in a **text/plain** resource.)
3. Let *file* be a **serialization of this canvas element's bitmap as a file**<sup>p747</sup>, passing *type* and *quality* if given.
4. If *file* is null then return "data: ,".
5. Return a **data: URL** representing *file*. **[RFC2397]**<sup>p1481</sup>

The **`toBlob`**(*callback*, *type*, *quality*) method, when invoked, must run these steps:

1. If this **canvas**<sup>p677</sup> element's **origin-clean**<sup>p678</sup> flag is set to false, then throw a "**SecurityError**" **DOMException**.
2. Let *result* be null.
3. If this **canvas**<sup>p677</sup> element's bitmap has pixels (i.e., neither its horizontal dimension nor its vertical dimension is zero), then set *result* to a copy of this **canvas**<sup>p677</sup> element's bitmap.
4. Run these steps **in parallel**<sup>p43</sup>:
  1. If *result* is non-null, then set *result* to a **serialization of result as a file**<sup>p747</sup> with *type* and *quality* if given.
  2. **Queue an element task**<sup>p1125</sup> on the **canvas blob serialization task source** given the **canvas**<sup>p677</sup> element to run these steps:
    1. If *result* is non-null, then set *result* to a new **Blob** object, created in the **relevant realm**<sup>p1083</sup> of this **canvas**<sup>p677</sup> element, representing *result*. **[FILEAPI]**<sup>p1478</sup>
    2. **Invoke** *callback* with « *result* » and "report".

The **`transferControlToOffscreen`**() method, when invoked, must run these steps:

1. If this **canvas**<sup>p677</sup> element's **context mode**<sup>p679</sup> is not set to **none**<sup>p679</sup>, throw an "**InvalidStateError**" **DOMException**.
2. Let *offscreenCanvas* be a new **OffscreenCanvas**<sup>p741</sup> object with its width and height equal to the values of the **width**<sup>p678</sup> and **height**<sup>p678</sup> content attributes of this **canvas**<sup>p677</sup> element.
3. Set the **placeholder canvas element**<sup>p742</sup> of *offscreenCanvas* to a weak reference to this **canvas**<sup>p677</sup> element.
4. Set this **canvas**<sup>p677</sup> element's **context mode**<sup>p679</sup> to **placeholder**<sup>p679</sup>.
5. Return *offscreenCanvas*.

#### Note

To maintain compatibility with existing web content, user agents need to enumerate methods defined in [CanvasUserInterface](#)<sup>p684</sup> immediately after the [stroke\(\)](#)<sup>p720</sup> method on [CanvasRenderingContext2D](#)<sup>p682</sup> objects.

#### For web developers (non-normative)

**context** = [canvas.getContext\(\)](#)<sup>p679</sup>('2d' [, { [ [alpha](#)<sup>p688</sup>: true ] [, [desynchronized](#)<sup>p688</sup>: false ] [, [colorSpace](#)<sup>p688</sup>: 'srgb' ] [, [willReadFrequently](#)<sup>p688</sup>: false ] } ])

Returns a [CanvasRenderingContext2D](#)<sup>p682</sup> object that is permanently bound to a particular [canvas](#)<sup>p677</sup> element.

If the [alpha](#)<sup>p688</sup> member is false, then the context is forced to always be opaque.

If the [desynchronized](#)<sup>p688</sup> member is true, then the context might be [desynchronized](#)<sup>p687</sup>.

The [colorSpace](#)<sup>p688</sup> member specifies the [color space](#)<sup>p688</sup> of the rendering context.

If the `willReadFrequently`<sup>p688</sup> member is true, then the context is marked for [readback optimization](#)<sup>p687</sup>.

`context.canvas`<sup>p689</sup>

Returns the `canvas`<sup>p677</sup> element.

`attributes = context.getContextAttributes`<sup>p688</sup>()

Returns an object whose:

- `alpha`<sup>p687</sup> member is true if the context has an alpha channel, or false if it was forced to be opaque.
- `desynchronized`<sup>p688</sup> member is true if the context can be [desynchronized](#)<sup>p687</sup>.
- `colorSpace`<sup>p688</sup> member is a string indicating the context's [color space](#)<sup>p688</sup>.
- `willReadFrequently`<sup>p688</sup> member is true if the context is marked for [readback optimization](#)<sup>p687</sup>.

A `CanvasRenderingContext2D`<sup>p682</sup> object has an **output bitmap** that is initialized when the object is created.

The [output bitmap](#)<sup>p687</sup> has an [origin-clean](#)<sup>p678</sup> flag, which can be set to true or false. Initially, when one of these bitmaps is created, its [origin-clean](#)<sup>p678</sup> flag must be set to true.

The `CanvasRenderingContext2D`<sup>p682</sup> object also has an **alpha** boolean. When a `CanvasRenderingContext2D`<sup>p682</sup> object's [alpha](#)<sup>p687</sup> is false, then its alpha channel must be fixed to 1.0 (fully opaque) for all pixels, and attempts to change the alpha component of any pixel must be silently ignored.

#### Note

*Thus, the bitmap of such a context starts off as [opaque black](#) instead of [transparent black](#); `clearRect()`<sup>p716</sup> always results in [opaque black](#) pixels, every fourth byte from `getImageData()`<sup>p727</sup> is always 255, the `putImageData()`<sup>p728</sup> method effectively ignores every fourth byte in its input, and so on. However, the alpha component of styles and images drawn onto the canvas are still honoured up to the point where they would impact the [output bitmap](#)<sup>p687</sup>'s alpha channel; for instance, drawing a 50% transparent white square on a freshly created [output bitmap](#)<sup>p687</sup> with its [alpha](#)<sup>p687</sup> set to false will result in a fully-opaque gray square.*

The `CanvasRenderingContext2D`<sup>p682</sup> object also has a **desynchronized** boolean. When a `CanvasRenderingContext2D`<sup>p682</sup> object's [desynchronized](#)<sup>p687</sup> is true, then the user agent may optimize the rendering of the canvas to reduce the latency, as measured from input events to rasterization, by desynchronizing the canvas paint cycle from the event loop, bypassing the ordinary user agent rendering algorithm, or both. Insofar as this mode involves bypassing the usual paint mechanisms, rasterization, or both, it might introduce visible tearing artifacts.

#### Note

*The user agent usually renders on a buffer which is not being displayed, quickly swapping it and the one being scanned out for presentation; the former buffer is called back buffer and the latter front buffer. A popular technique for reducing latency is called front buffer rendering, also known as single buffer rendering, where rendering happens in parallel and rapidly with the scanning out process. This technique reduces the latency at the price of potentially introducing tearing artifacts and can be used to implement in total or part of the [desynchronized](#)<sup>p687</sup> boolean. [\[MULTIPLEBUFFERING\]](#)<sup>p1480</sup>*

#### Note

*The [desynchronized](#)<sup>p687</sup> boolean can be useful when implementing certain kinds of applications, such as drawing applications, where the latency between input and rasterization is critical.*

The `CanvasRenderingContext2D`<sup>p682</sup> object also has a **will read frequently** boolean. When a `CanvasRenderingContext2D`<sup>p682</sup> object's [will read frequently](#)<sup>p687</sup> is true, the user agent may optimize the canvas for readback operations.

#### Note

*On most devices the user agent needs to decide whether to store the canvas's [output bitmap](#)<sup>p687</sup> on the GPU (this is also called "hardware accelerated"), or on the CPU (also called "software"). Most rendering operations are more performant for accelerated canvases, with the major exception being readback with `getImageData()`<sup>p727</sup>, `toDataURL()`<sup>p681</sup>, or `toBlob()`<sup>p681</sup>. `CanvasRenderingContext2D`<sup>p682</sup> objects with [will read frequently](#)<sup>p687</sup> equal to true tell the user agent that the webpage is likely to perform many readback operations and that it is advantageous to use a software canvas.*

The [CanvasRenderingContext2D](#)<sup>p682</sup> object also has a **color space** setting of type [PredefinedColorSpace](#)<sup>p682</sup>. The [CanvasRenderingContext2D](#)<sup>p682</sup> object's [color space](#)<sup>p688</sup> indicates the color space for the [output bitmap](#)<sup>p687</sup>.

The [getContextAttributes\(\)](#) method steps are to return «[ "[alpha](#)"<sup>p688</sup> → [this's alpha](#)<sup>p687</sup>, "[desynchronized](#)"<sup>p688</sup> → [this's desynchronized](#)<sup>p687</sup>, "[colorSpace](#)"<sup>p688</sup> → [this's color space](#)<sup>p688</sup>, "[willReadFrequently](#)"<sup>p688</sup> → [this's will read frequently](#)<sup>p687</sup> ]».

The [CanvasRenderingContext2D](#)<sup>p682</sup> 2D rendering context represents a flat linear Cartesian surface whose origin (0,0) is at the top left corner, with the coordinate space having x values increasing when going right, and y values increasing when going down. The x-coordinate of the right-most edge is equal to the width of the rendering context's [output bitmap](#)<sup>p687</sup> in [CSS pixels](#); similarly, the y-coordinate of the bottom-most edge is equal to the height of the rendering context's [output bitmap](#)<sup>p687</sup> in [CSS pixels](#).

The size of the coordinate space does not necessarily represent the size of the actual bitmaps that the user agent will use internally or during rendering. On high-definition displays, for instance, the user agent may internally use bitmaps with four device pixels per unit in the coordinate space, so that the rendering remains at high quality throughout. Anti-aliasing can similarly be implemented using oversampling with bitmaps of a higher resolution than the final image on the display.

#### Example

Using [CSS pixels](#) to describe the size of a rendering context's [output bitmap](#)<sup>p687</sup> does not mean that when rendered the canvas will cover an equivalent area in [CSS pixels](#). [CSS pixels](#) are reused for ease of integration with CSS features, such as text layout.

In other words, the [canvas](#)<sup>p677</sup> element below's rendering context has a 200x200 [output bitmap](#)<sup>p687</sup> (which internally uses [CSS pixels](#) as a unit for ease of integration with CSS) and is rendered as 100x100 [CSS pixels](#):

```
<canvas width=200 height=200 style=width:100px;height:100px>
```

The **2D context creation algorithm**, which is passed a *target* (a [canvas](#)<sup>p677</sup> element) and *options*, consists of running these steps:

1. Let *settings* be the result of [converting options](#) to the dictionary type [CanvasRenderingContext2DSettings](#)<sup>p682</sup>. (This can throw an exception.).
2. Let *context* be a new [CanvasRenderingContext2D](#)<sup>p682</sup> object.
3. Initialize *context*'s [canvas](#)<sup>p689</sup> attribute to point to *target*.
4. Set *context*'s [output bitmap](#)<sup>p687</sup> to the same bitmap as *target*'s bitmap (so that they are shared).
5. Set [bitmap dimensions](#)<sup>p688</sup> to [the numeric values](#)<sup>p678</sup> of *target*'s [width](#)<sup>p678</sup> and [height](#)<sup>p678</sup> content attributes.
6. Set *context*'s [alpha](#)<sup>p687</sup> to *settings*["[alpha](#)"].
7. Set *context*'s [desynchronized](#)<sup>p687</sup> to *settings*["[desynchronized](#)"].
8. Set *context*'s [color space](#)<sup>p688</sup> to *settings*["[colorSpace](#)"].
9. Set *context*'s [will read frequently](#)<sup>p687</sup> to *settings*["[willReadFrequently](#)"].
10. Return *context*.

When the user agent is to **set bitmap dimensions** to *width* and *height*, it must run these steps:

1. [Reset the rendering context to its default state](#)<sup>p690</sup>.
2. Resize the [output bitmap](#)<sup>p687</sup> to the new *width* and *height*.
3. Let *canvas* be the [canvas](#)<sup>p677</sup> element to which the rendering context's [canvas](#)<sup>p689</sup> attribute was initialized.
4. If [the numeric value](#)<sup>p678</sup> of *canvas*'s [width](#)<sup>p678</sup> content attribute differs from *width*, then set *canvas*'s [width](#)<sup>p678</sup> content attribute to the shortest possible string representing *width* as a [valid non-negative integer](#)<sup>p77</sup>.
5. If [the numeric value](#)<sup>p678</sup> of *canvas*'s [height](#)<sup>p678</sup> content attribute differs from *height*, then set *canvas*'s [height](#)<sup>p678</sup> content attribute to the shortest possible string representing *height* as a [valid non-negative integer](#)<sup>p77</sup>.

### Example

Only one square appears to be drawn in the following example:

```
// canvas is a reference to a <canvas> element
var context = canvas.getContext('2d');
context.fillRect(0,0,50,50);
canvas.setAttribute('width', '300'); // clears the canvas
context.fillRect(0,100,50,50);
canvas.width = canvas.width; // clears the canvas
context.fillRect(100,0,50,50); // only this square remains
```

The **canvas** attribute must return the value it was initialized to when the object was created.

The [PredefinedColorSpace](#)<sup>p682</sup> enumeration is used to specify the [color space](#)<sup>p688</sup> of the canvas's backing store.

The **"srgb"** value indicates the ['srgb'](#) color space.

The **"display-p3"** value indicates the ['display-p3'](#) color space.

### Note

*The algorithm for converting between color spaces can be found in the [Converting Colors](#) section of CSS Color. [\[CSSCOLOR\]](#)<sup>p1476</sup>*

The [CanvasFillRule](#)<sup>p682</sup> enumeration is used to select the **fill rule** algorithm by which to determine if a point is inside or outside a path.

The value **"nonzero"** value indicates the nonzero winding rule, wherein a point is considered to be outside a shape if the number of times a half-infinite straight line drawn from that point crosses the shape's path going in one direction is equal to the number of times it crosses the path going in the other direction.

The **"evenodd"** value indicates the even-odd rule, wherein a point is considered to be outside a shape if the number of times a half-infinite straight line drawn from that point crosses the shape's path is even.

If a point is not outside a shape, it is inside the shape.

The [ImageSmoothingQuality](#)<sup>p682</sup> enumeration is used to express a preference for the interpolation quality to use when smoothing images.

The **"low"** value indicates a preference for a low level of image interpolation quality. Low-quality image interpolation may be more computationally efficient than higher settings.

The **"medium"** value indicates a preference for a medium level of image interpolation quality.

The **"high"** value indicates a preference for a high level of image interpolation quality. High-quality image interpolation may be more computationally expensive than lower settings.

### Note

*Bilinear scaling is an example of a relatively fast, lower-quality image-smoothing algorithm. Bicubic or Lanczos scaling are examples of image-smoothing algorithms that produce higher-quality output. This specification does not mandate that specific interpolation algorithms be used.*

#### 4.12.5.1.1 Implementation notes <sup>p688</sup><sub>9</sub>

*This section is non-normative.*

The [output bitmap](#)<sup>p687</sup>, when it is not directly displayed by the user agent, implementations can, instead of updating this bitmap, merely remember the sequence of drawing operations that have been applied to it until such time as the bitmap's actual data is

needed (for example because of a call to [drawImage\(\)](#)<sup>p723</sup>, or the [createImageBitmap\(\)](#)<sup>p1182</sup> factory method). In many cases, this will be more memory efficient.

The bitmap of a [canvas](#)<sup>p677</sup> element is the one bitmap that's pretty much always going to be needed in practice. The [output bitmap](#)<sup>p687</sup> of a rendering context, when it has one, is always just an alias to a [canvas](#)<sup>p677</sup> element's bitmap.

Additional bitmaps are sometimes needed, e.g. to enable fast drawing when the canvas is being painted at a different size than its [natural size](#), or to enable double buffering so that graphics updates, like page scrolling for example, can be processed concurrently while canvas draw commands are being executed.

#### 4.12.5.1.2 The canvas state <sup>p69</sup><sub>0</sub>

Objects that implement the [CanvasState](#)<sup>p682</sup> interface maintain a stack of drawing states. **Drawing states** consist of:

- The current [transformation matrix](#)<sup>p709</sup>.
- The current [clipping region](#)<sup>p720</sup>.
- The current [letter spacing](#)<sup>p697</sup>, [word spacing](#)<sup>p697</sup>, [fill style](#)<sup>p712</sup>, [stroke style](#)<sup>p712</sup>, [filter](#)<sup>p733</sup>, [global alpha](#)<sup>p731</sup>, [compositing and blending operator](#)<sup>p731</sup>, and [shadow color](#)<sup>p732</sup>.
- The current values of the following attributes: [lineWidth](#)<sup>p691</sup>, [lineCap](#)<sup>p691</sup>, [lineJoin](#)<sup>p692</sup>, [miterLimit](#)<sup>p692</sup>, [lineDashOffset](#)<sup>p692</sup>, [shadowOffsetX](#)<sup>p732</sup>, [shadowOffsetY](#)<sup>p732</sup>, [shadowBlur](#)<sup>p732</sup>, [font](#)<sup>p696</sup>, [textAlign](#)<sup>p697</sup>, [textBaseline](#)<sup>p697</sup>, [direction](#)<sup>p697</sup>, [fontKerning](#)<sup>p697</sup>, [fontStretch](#)<sup>p697</sup>, [fontVariantCaps](#)<sup>p698</sup>, [textRendering](#)<sup>p698</sup>, [imageSmoothingEnabled](#)<sup>p731</sup>, [imageSmoothingQuality](#)<sup>p731</sup>.
- The current [dash list](#)<sup>p692</sup>.

#### Note

*The rendering context's bitmaps are not part of the drawing state, as they depend on whether and how the rendering context is bound to a [canvas](#)<sup>p677</sup> element.*

Objects that implement the [CanvasState](#)<sup>p682</sup> mixin have a **context lost** boolean, that is initialized to false when the object is created. The [context lost](#)<sup>p690</sup> value is updated in the [context lost steps](#)<sup>p1129</sup>.

#### For web developers (non-normative)

##### **context.save**<sup>p690</sup>()

Pushes the current state onto the stack.

##### **context.restore**<sup>p690</sup>()

Pops the top state on the stack, restoring the context to that state.

##### **context.reset**<sup>p690</sup>()

Resets the rendering context, which includes the backing buffer, the drawing state stack, path, and styles.

##### **context.isContextLost**<sup>p691</sup>()

Returns true if the rendering context was lost. Context loss can occur due to driver crashes, running out of memory, etc. In these cases, the canvas loses its backing storage and takes steps to [reset the rendering context to its default state](#)<sup>p690</sup>.

The **save()** method steps are to push a copy of the current drawing state onto the drawing state stack.

The **restore()** method steps are to pop the top entry in the drawing state stack, and reset the drawing state it describes. If there is no saved state, then the method must do nothing.

The **reset()** method steps are to [reset the rendering context to its default state](#)<sup>p690</sup>.

To **reset the rendering context to its default state**:

1. Clear canvas's bitmap to [transparent black](#).
2. Empty the list of subpaths in context's [current default path](#)<sup>p719</sup>.
3. Clear the context's drawing state stack.

4. Reset everything that [drawing state](#)<sup>p690</sup> consists of to their initial values.

The `isContextLost()` method steps are to return [this's context lost](#)<sup>p690</sup>.

#### 4.12.5.1.3 Line styles <sup>p69</sup><sub>1</sub>

For web developers (non-normative)

**`context.lineWidth`**<sup>p691</sup> [ = *value* ]

**`styles.lineWidth`**<sup>p691</sup> [ = *value* ]

Returns the current line width.

Can be set, to change the line width. Values that are not finite values greater than zero are ignored.

**`context.lineCap`**<sup>p691</sup> [ = *value* ]

**`styles.lineCap`**<sup>p691</sup> [ = *value* ]

Returns the current line cap style.

Can be set, to change the line cap style.

The possible line cap styles are "butt", "round", and "square". Other values are ignored.

**`context.lineJoin`**<sup>p692</sup> [ = *value* ]

**`styles.lineJoin`**<sup>p692</sup> [ = *value* ]

Returns the current line join style.

Can be set, to change the line join style.

The possible line join styles are "bevel", "round", and "miter". Other values are ignored.

**`context.miterLimit`**<sup>p692</sup> [ = *value* ]

**`styles.miterLimit`**<sup>p692</sup> [ = *value* ]

Returns the current miter limit ratio.

Can be set, to change the miter limit ratio. Values that are not finite values greater than zero are ignored.

**`context.setLineDash`**<sup>p692</sup> (*segments*)

**`styles.setLineDash`**<sup>p692</sup> (*segments*)

Sets the current line dash pattern (as used when stroking). The argument is a list of distances for which to alternately have the line on and the line off.

*segments* = **`context.getLineDash`**<sup>p692</sup> ()

*segments* = **`styles.getLineDash`**<sup>p692</sup> ()

Returns a copy of the current line dash pattern. The array returned will always have an even number of entries (i.e. the pattern is normalized).

**`context.lineDashOffset`**<sup>p692</sup>

**`styles.lineDashOffset`**<sup>p692</sup>

Returns the phase offset (in the same units as the line dash pattern).

Can be set, to change the phase offset. Values that are not finite values are ignored.

Objects that implement the [CanvasPathDrawingStyles](#)<sup>p685</sup> interface have attributes and methods (defined in this section) that control how lines are treated by the object.

The **`lineWidth`** attribute gives the width of lines, in coordinate space units. On getting, it must return the current value. On setting, zero, negative, infinite, and NaN values must be ignored, leaving the value unchanged; other values must change the current value to the new value.

When the object implementing the [CanvasPathDrawingStyles](#)<sup>p685</sup> interface is created, the **`lineWidth`**<sup>p691</sup> attribute must initially have the value 1.0.

The **`lineCap`** attribute defines the type of endings that UAs will place on the end of lines. The three valid values are "butt", "round", and "square".

On getting, it must return the current value. On setting, the current value must be changed to the new value.

When the object implementing the [CanvasPathDrawingStyles](#)<sup>p685</sup> interface is created, the [lineCap](#)<sup>p691</sup> attribute must initially have the value "butt".

The [lineJoin](#) attribute defines the type of corners that UAs will place where two lines meet. The three valid values are "bevel", "round", and "miter".

On getting, it must return the current value. On setting, the current value must be changed to the new value.

When the object implementing the [CanvasPathDrawingStyles](#)<sup>p685</sup> interface is created, the [lineJoin](#)<sup>p692</sup> attribute must initially have the value "miter".

When the [lineJoin](#)<sup>p692</sup> attribute has the value "miter", strokes use the miter limit ratio to decide how to render joins. The miter limit ratio can be explicitly set using the [miterLimit](#) attribute. On getting, it must return the current value. On setting, zero, negative, infinite, and NaN values must be ignored, leaving the value unchanged; other values must change the current value to the new value.

When the object implementing the [CanvasPathDrawingStyles](#)<sup>p685</sup> interface is created, the [miterLimit](#)<sup>p692</sup> attribute must initially have the value 10.0.

Each [CanvasPathDrawingStyles](#)<sup>p685</sup> object has a **dash list**, which is either empty or consists of an even number of non-negative numbers. Initially, the [dash list](#)<sup>p692</sup> must be empty.

The [setLineDash\(\*segments\*\)](#) method, when invoked, must run these steps:

1. If any value in *segments* is not finite (e.g. an Infinity or a NaN value), or if any value is negative (less than zero), then return (without throwing an exception; user agents could show a message on a developer console, though, as that would be helpful for debugging).
2. If the number of elements in *segments* is odd, then let *segments* be the concatenation of two copies of *segments*.
3. Let the object's [dash list](#)<sup>p692</sup> be *segments*.

When the [getLineDash\(\)](#) method is invoked, it must return a sequence whose values are the values of the object's [dash list](#)<sup>p692</sup>, in the same order.

It is sometimes useful to change the "phase" of the dash pattern, e.g. to achieve a "marching ants" effect. The phase can be set using the [lineDashOffset](#) attribute. On getting, it must return the current value. On setting, infinite and NaN values must be ignored, leaving the value unchanged; other values must change the current value to the new value.

When the object implementing the [CanvasPathDrawingStyles](#)<sup>p685</sup> interface is created, the [lineDashOffset](#)<sup>p692</sup> attribute must initially have the value 0.0.

When a user agent is to **trace a path**, given an object *style* that implements the [CanvasPathDrawingStyles](#)<sup>p685</sup> interface, it must run the following algorithm. This algorithm returns a new [path](#)<sup>p702</sup>.

1. Let *path* be a copy of the path being traced.
2. Prune all zero-length [line segments](#)<sup>p702</sup> from *path*.
3. Remove from *path* any subpaths containing no lines (i.e. subpaths with just one point).
4. Replace each point in each subpath of *path* other than the first point and the last point of each subpath by a *join* that joins the line leading to that point to the line leading out of that point, such that the subpaths all consist of two points (a starting point with a line leading out of it, and an ending point with a line leading into it), one or more lines (connecting the points and the joins), and zero or more joins (each connecting one line to another), connected together such that each subpath is a series of one or more lines with a join between each one and a point on each end.
5. Add a straight closing line to each closed subpath in *path* connecting the last point and the first point of that subpath; change the last point to a join (from the previously last line to the newly added closing line), and change the first point to a join (from the newly added closing line to the first line).

6. If style's [dash list](#)<sup>p692</sup> is empty, then jump to the step labeled *convert*.
7. Let *pattern width* be the concatenation of all the entries of style's [dash list](#)<sup>p692</sup>, in coordinate space units.
8. For each subpath *subpath* in *path*, run the following substeps. These substeps mutate the subpaths in *path in vivo*.
  1. Let *subpath width* be the length of all the lines of *subpath*, in coordinate space units.
  2. Let *offset* be the value of style's [LineDashOffset](#)<sup>p692</sup>, in coordinate space units.
  3. While *offset* is greater than *pattern width*, decrement it by *pattern width*.  
While *offset* is less than zero, increment it by *pattern width*.
  4. Define *L* to be a linear coordinate line defined along all lines in *subpath*, such that the start of the first line in the subpath is defined as coordinate 0, and the end of the last line in the subpath is defined as coordinate *subpath width*.
  5. Let *position* be zero minus *offset*.
  6. Let *index* be 0.
  7. Let *current state* be *off* (the other states being *on* and *zero-on*).
  8. *Dash on*: Let *segment length* be the value of style's [dash list](#)<sup>p692</sup>'s *indexth* entry.
  9. Increment *position* by *segment length*.
  10. If *position* is greater than *subpath width*, then end these substeps for this subpath and start them again for the next subpath; if there are no more subpaths, then jump to the step labeled *convert* instead.
  11. If *segment length* is nonzero, then let *current state* be *on*.
  12. Increment *index* by one.
  13. *Dash off*: Let *segment length* be the value of style's [dash list](#)<sup>p692</sup>'s *indexth* entry.
  14. Let *start* be the offset *position* on *L*.
  15. Increment *position* by *segment length*.
  16. If *position* is less than zero, then jump to the step labeled *post-cut*.
  17. If *start* is less than zero, then let *start* be zero.
  18. If *position* is greater than *subpath width*, then let *end* be the offset *subpath width* on *L*. Otherwise, let *end* be the offset *position* on *L*.
  19. Jump to the first appropriate step:

↪ **If segment length is zero and current state is off**

Do nothing, just continue to the next step.

↪ **If current state is off**

Cut the line on which *end* finds itself short at *end* and place a point there, cutting in two the subpath that it was in; remove all line segments, joins, points, and subpaths that are between *start* and *end*; and finally place a single point at *start* with no lines connecting to it.

The point has a *directionality* for the purposes of drawing line caps (see below). The directionality is the direction that the original line had at that point (i.e. when *L* was defined above).

↪ **Otherwise**

Cut the line on which *start* finds itself into two at *start* and place a point there, cutting in two the subpath that it was in, and similarly cut the line on which *end* finds itself short at *end* and place a point there, cutting in two the subpath that it was in, and then remove all line segments, joins, points, and subpaths that are between *start* and *end*.

If *start* and *end* are the same point, then this results in just the line being cut in two and two points being inserted there, with nothing being removed, unless a join also happens to be at that point, in which case the join must be removed.

20. *Post-cut*: If *position* is greater than *subpath width*, then jump to the step labeled *convert*.
21. If *segment length* is greater than zero, then let *positioned-at-on-dash* be false.
22. Increment *index* by one. If it is equal to the number of entries in *style's dash list*<sup>p692</sup>, then let *index* be 0.
23. Return to the step labeled *dash on*.

9. *Convert*: This is the step that converts the path to a new path that represents its stroke.

Create a new *path*<sup>p702</sup> that describes the edge of the areas that would be covered if a straight line of length equal to *style's lineWidth*<sup>p691</sup> was swept along each subpath in *path* while being kept at an angle such that the line is orthogonal to the path being swept, replacing each point with the end cap necessary to satisfy *style's lineCap*<sup>p691</sup> attribute as described previously and elaborated below, and replacing each join with the join necessary to satisfy *style's lineJoin*<sup>p692</sup> type, as defined below.

**Caps:** Each point has a flat edge perpendicular to the direction of the line coming out of it. This is then augmented according to the value of *style's lineCap*<sup>p691</sup>. The "butt" value means that no additional line cap is added. The "round" value means that a semi-circle with the diameter equal to *style's lineWidth*<sup>p691</sup> width must additionally be placed on to the line coming out of each point. The "square" value means that a rectangle with the length of *style's lineWidth*<sup>p691</sup> width and the width of half *style's lineWidth*<sup>p691</sup> width, placed flat against the edge perpendicular to the direction of the line coming out of the point, must be added at each point.

Points with no lines coming out of them must have two caps placed back-to-back as if it was really two points connected to each other by an infinitesimally short straight line in the direction of the point's *directionality* (as defined above).

**Joins:** In addition to the point where a join occurs, two additional points are relevant to each join, one for each line: the two corners found half the line width away from the join point, one perpendicular to each line, each on the side furthest from the other line.

A triangle connecting these two opposite corners with a straight line, with the third point of the triangle being the join point, must be added at all joins. The *lineJoin*<sup>p692</sup> attribute controls whether anything else is rendered. The three aforementioned values have the following meanings:

The "bevel" value means that this is all that is rendered at joins.

The "round" value means that an arc connecting the two aforementioned corners of the join, abutting (and not overlapping) the aforementioned triangle, with the diameter equal to the line width and the origin at the point of the join, must be added at joins.

The "miter" value means that a second triangle must (if it can given the miter length) be added at the join, with one line being the line between the two aforementioned corners, abutting the first triangle, and the other two being continuations of the outside edges of the two joining lines, as long as required to intersect without going over the miter length.

The miter length is the distance from the point where the join occurs to the intersection of the line edges on the outside of the join. The miter limit ratio is the maximum allowed ratio of the miter length to half the line width. If the miter length would cause the miter limit ratio (as set by *style's miterLimit*<sup>p692</sup> attribute) to be exceeded, then this second triangle must not be added.

The subpaths in the newly created path must be oriented such that for any point, the number of times a half-infinite straight line drawn from that point crosses a subpath is even if and only if the number of times a half-infinite straight line drawn from that same point crosses a subpath going in one direction is equal to the number of times it crosses a subpath going in the other direction.

10. Return the newly created path.

#### 4.12.5.1.4 Text styles §<sup>p69</sup><sub>4</sub>

For web developers (non-normative)

**context.font**<sup>p696</sup> [ = value ]

**styles.font**<sup>p696</sup> [ = value ]

Returns the current font settings.

Can be set, to change the font. The syntax is the same as for the CSS '[font](#)' property; values that cannot be parsed as CSS font values are ignored.

Relative keywords and lengths are computed relative to the font of the [canvas](#)<sup>p677</sup> element.

**context.textAlign**<sup>p697</sup> [ = value ]

**styles.textAlign**<sup>p697</sup> [ = value ]

Returns the current text alignment settings.

Can be set, to change the alignment. The possible values are and their meanings are given below. Other values are ignored. The default is "start".

**context.textBaseline**<sup>p697</sup> [ = value ]

**styles.textBaseline**<sup>p697</sup> [ = value ]

Returns the current baseline alignment settings.

Can be set, to change the baseline alignment. The possible values and their meanings are given below. Other values are ignored. The default is "alphabetic"<sup>p698</sup>.

**context.direction**<sup>p697</sup> [ = value ]

**styles.direction**<sup>p697</sup> [ = value ]

Returns the current directionality.

Can be set, to change the directionality. The possible values and their meanings are given below. Other values are ignored. The default is "inherit"<sup>p699</sup>.

**context.letterSpacing**<sup>p697</sup> [ = value ]

**styles.letterSpacing**<sup>p697</sup> [ = value ]

Returns the current spacing between characters in the text.

Can be set, to change spacing between characters. Values that cannot be parsed as a CSS [<length>](#) are ignored. The default is "0px".

**context.fontKerning**<sup>p697</sup> [ = value ]

**styles.fontKerning**<sup>p697</sup> [ = value ]

Returns the current font kerning settings.

Can be set, to change the font kerning. The possible values and their meanings are given below. Other values are ignored. The default is "auto"<sup>p699</sup>.

**context.fontStretch**<sup>p697</sup> [ = value ]

**styles.fontStretch**<sup>p697</sup> [ = value ]

Returns the current font stretch settings.

Can be set, to change the font stretch. The possible values and their meanings are given below. Other values are ignored. The default is "normal"<sup>p699</sup>.

**context.fontVariantCaps**<sup>p698</sup> [ = value ]

**styles.fontVariantCaps**<sup>p698</sup> [ = value ]

Returns the current font variant caps settings.

Can be set, to change the font variant caps. The possible values and their meanings are given below. Other values are ignored. The default is "normal"<sup>p699</sup>.

**context.textRendering**<sup>p698</sup> [ = value ]

**styles.textRendering**<sup>p698</sup> [ = value ]

Returns the current text rendering settings.

Can be set, to change the text rendering. The possible values and their meanings are given below. Other values are ignored. The default is "auto"<sup>p700</sup>.

**context.wordSpacing**<sup>p697</sup> [ = value ]

**styles.wordSpacing**<sup>p697</sup> [ = value ]

Returns the current spacing between words in the text.

Can be set, to change spacing between words. Values that cannot be parsed as a CSS [<length>](#) are ignored. The default is "0px".

Objects that implement the [CanvasTextDrawingStyles](#)<sup>p685</sup> interface have attributes (defined in this section) that control how text is laid out (rasterized or outlined) by the object. Such objects can also have a **font style source object**. For [CanvasRenderingContext2D](#)<sup>p682</sup> objects, this is the [canvas](#)<sup>p677</sup> element given by the value of the context's [canvas](#)<sup>p689</sup> attribute. For [OffscreenCanvasRenderingContext2D](#)<sup>p745</sup> objects, this is the [associated OffscreenCanvas object](#)<sup>p746</sup>.

Font resolution for the [font style source object](#)<sup>p695</sup> requires a [font source](#). This is determined for a given *object* implementing [CanvasTextDrawingStyles](#)<sup>p685</sup> by the following steps: [\[CSSFONTLOAD\]](#)<sup>p1476</sup>

1. If *object*'s [font style source object](#)<sup>p695</sup> is a [canvas](#)<sup>p677</sup> element, return the element's [node document](#).
2. Otherwise, *object*'s [font style source object](#)<sup>p695</sup> is an [OffscreenCanvas](#)<sup>p741</sup> object:
  1. Let *global* be *object*'s [relevant global object](#)<sup>p1083</sup>.
  2. If *global* is a [Window](#)<sup>p922</sup> object, then return *global*'s [associated Document](#)<sup>p923</sup>.
  3. **Assert:** *global* implements [WorkerGlobalScope](#)<sup>p1228</sup>.
  4. Return *global*.

#### Example

This is an example of font resolution with a regular [canvas](#)<sup>p677</sup> element with ID c1.

```
const font = new FontFace("MyCanvasFont", "url(mycanvasfont.ttf)");
documents.fonts.add(font);

const context = document.getElementById("c1").getContext("2d");
document.fonts.ready.then(function() {
  context.font = "64px MyCanvasFont";
  context.fillText("hello", 0, 0);
});
```

In this example, the canvas will display text using mycanvasfont.ttf as its font.

#### Example

This is an example of how font resolution can happen using [OffscreenCanvas](#)<sup>p741</sup>. Assuming a [canvas](#)<sup>p677</sup> element with ID c2 which is transferred to a worker like so:

```
const offscreenCanvas = document.getElementById("c2").transferControlToOffscreen();
worker.postMessage(offscreenCanvas, [offscreenCanvas]);
```

Then, in the worker:

```
self.onmessage = function(ev) {
  const transferredCanvas = ev.data;
  const context = transferredCanvas.getContext("2d");
  const font = new FontFace("MyFont", "url(myfont.ttf)");
  self.fonts.add(font);
  self.fonts.ready.then(function() {
    context.font = "64px MyFont";
    context.fillText("hello", 0, 0);
  });
};
```

In this example, the canvas will display a text using myfont.ttf. Notice that the font is only loaded inside the worker, and not in the document context.

The **font** IDL attribute, on setting, must be [parsed as a CSS <'font'> value](#) (but without supporting property-independent style sheet syntax like 'inherit'), and the resulting font must be assigned to the context, with the **'line-height'** component forced to 'normal', with the **'font-size'** component converted to [CSS pixels](#), and with system fonts being computed to explicit values. If the new value is syntactically incorrect (including using property-independent style sheet syntax like 'inherit' or 'initial'), then it must be ignored, without assigning a new font value. [\[CSS\]](#)<sup>p1476</sup>

Font family names must be interpreted in the context of the [font style source object](#)<sup>p695</sup> when the font is to be used; any fonts embedded using @font-face or loaded using [FontFace](#)<sup>p67</sup> objects that are visible to the [font style source object](#)<sup>p695</sup> must therefore be available once they are loaded. (Each [font style source object](#)<sup>p695</sup> has a [font source](#), which determines what fonts are available.) If a font is used before it is fully loaded, or if the [font style source object](#)<sup>p695</sup> does not have that font in scope at the time the font is to be

used, then it must be treated as if it was an unknown font, falling back to another as described by the relevant CSS specifications. [\[CSSFONTSS\]](#)<sup>p1476</sup> [\[CSSFONTLOAD\]](#)<sup>p1476</sup>

On getting, the [font](#)<sup>p696</sup> attribute must return the [serialized form](#) of the current font of the context (with no ['line-height'](#) component). [\[CSSOM\]](#)<sup>p1477</sup>

#### Example

For example, after the following statement:

```
context.font = 'italic 400 12px/2 Unknown Font, sans-serif';
```

...the expression `context.font` would evaluate to the string `"italic 12px "Unknown Font", sans-serif"`. The `"400"` font-weight doesn't appear because that is the default value. The line-height doesn't appear because it is forced to `"normal"`, the default value.

When the object implementing the [CanvasTextDrawingStyles](#)<sup>p685</sup> interface is created, the font of the context must be set to 10px sans-serif. When the ['font-size'](#) component is set to lengths using percentages, ['em'](#) or ['ex'](#) units, or the ['larger'](#) or ['smaller'](#) keywords, these must be interpreted relative to the [computed value](#) of the ['font-size'](#) property of the [font style source object](#)<sup>p695</sup> at the time that the attribute is set, if it is an element. When the ['font-weight'](#) component is set to the relative values ['bolder'](#) and ['lighter'](#), these must be interpreted relative to the [computed value](#) of the ['font-weight'](#) property of the [font style source object](#)<sup>p695</sup> at the time that the attribute is set, if it is an element. If the [computed values](#) are undefined for a particular case (e.g. because the [font style source object](#)<sup>p695</sup> is not an element or is not [being rendered](#)<sup>p1388</sup>), then the relative keywords must be interpreted relative to the normal-weight 10px sans-serif default.

The [textAlign](#) IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the [CanvasTextDrawingStyles](#)<sup>p685</sup> interface is created, the [textAlign](#)<sup>p697</sup> attribute must initially have the value [start](#)<sup>p698</sup>.

The [textBaseline](#) IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the [CanvasTextDrawingStyles](#)<sup>p685</sup> interface is created, the [textBaseline](#)<sup>p697</sup> attribute must initially have the value [alphabetic](#)<sup>p698</sup>.

The [direction](#) IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the [CanvasTextDrawingStyles](#)<sup>p685</sup> interface is created, the [direction](#)<sup>p697</sup> attribute must initially have the value [inherit](#)<sup>p699</sup>.

Objects that implement the [CanvasTextDrawingStyles](#)<sup>p685</sup> interface have attributes that control the spacing between letters and words. Such objects have associated **letter spacing** and **word spacing** values, which are CSS [<length>](#) values. Initially, both must be the result of [parsing](#) `"0px"` as a CSS [<length>](#).

The [letterSpacing](#) getter steps are to return the [serialized form](#) of [this's letter spacing](#)<sup>p697</sup>.

The [letterSpacing](#)<sup>p697</sup> setter steps are:

1. Let *parsed* be the result of [parsing](#) the given value as a CSS [<length>](#).
2. If *parsed* is failure, then return.
3. Set [this's letter spacing](#)<sup>p697</sup> to *parsed*.

The [wordSpacing](#) getter steps are to return the [serialized form](#) of [this's word spacing](#)<sup>p697</sup>.

The [wordSpacing](#)<sup>p697</sup> setter steps are:

1. Let *parsed* be the result of [parsing](#) the given value as a CSS [<length>](#).
2. If *parsed* is failure, then return.
3. Set [this's word spacing](#)<sup>p697</sup> to *parsed*.

The [fontKerning](#) IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the [CanvasTextDrawingStyles](#)<sup>p685</sup> interface is created, the [fontKerning](#)<sup>p697</sup> attribute must initially have the value [auto](#)<sup>p699</sup>.

The [fontStretch](#) IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new

value. When the object implementing the [CanvasTextDrawingStyles](#)<sup>p685</sup> interface is created, the [fontStretch](#)<sup>p697</sup> attribute must initially have the value "[normal](#)<sup>p699</sup>".

The [fontVariantCaps](#) IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the [CanvasTextDrawingStyles](#)<sup>p685</sup> interface is created, the [fontVariantCaps](#)<sup>p698</sup> attribute must initially have the value "[normal](#)<sup>p699</sup>".

The [textRendering](#) IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the [CanvasTextDrawingStyles](#)<sup>p685</sup> interface is created, the [textRendering](#)<sup>p698</sup> attribute must initially have the value "[auto](#)<sup>p700</sup>".

The [textAlign](#)<sup>p697</sup> attribute's allowed keywords are as follows:

#### start

Align to the start edge of the text (left side in left-to-right text, right side in right-to-left text).

#### end

Align to the end edge of the text (right side in left-to-right text, left side in right-to-left text).

#### left

Align to the left.

#### right

Align to the right.

#### center

Align to the center.

The [textBaseline](#)<sup>p697</sup> attribute's allowed keywords correspond to alignment points in the font:

The keywords map to these alignment points as follows:

#### top

The [em-over baseline](#)

#### hanging

The [hanging baseline](#)

#### middle

Halfway between the [em-over baseline](#) and the [em-under baseline](#)

#### alphabetic

The [alphabetic baseline](#)

## **ideographic**

The [ideographic-under baseline](#)

## **bottom**

The [em-under baseline](#)

The [direction](#)<sup>p697</sup> attribute's allowed keywords are as follows:

## **ltr**

Treat input to the [text preparation algorithm](#)<sup>p700</sup> as left-to-right text.

## **rtl**

Treat input to the [text preparation algorithm](#)<sup>p700</sup> as right-to-left text.

## **inherit**

Default to the directionality of the [canvas](#)<sup>p677</sup> element or [Document](#)<sup>p130</sup> as appropriate.

The [fontKerning](#)<sup>p697</sup> attribute's allowed keywords are as follows:

## **auto**

Kerning is applied at the discretion of the user agent.

## **normal**

Kerning is applied.

## **none**

Kerning is not applied.

The [fontStretch](#)<sup>p697</sup> attribute's allowed keywords are as follows:

## **ultra-condensed**

Same as CSS ['font-stretch' 'ultra-condensed'](#) setting.

## **extra-condensed**

Same as CSS ['font-stretch' 'extra-condensed'](#) setting.

## **condensed**

Same as CSS ['font-stretch' 'condensed'](#) setting.

## **semi-condensed**

Same as CSS ['font-stretch' 'semi-condensed'](#) setting.

## **normal**

The default setting, where width of the glyphs is at 100%.

## **semi-expanded**

Same as CSS ['font-stretch' 'semi-expanded'](#) setting.

## **expanded**

Same as CSS ['font-stretch' 'expanded'](#) setting.

## **extra-expanded**

Same as CSS ['font-stretch' 'extra-expanded'](#) setting.

## **ultra-expanded**

Same as CSS ['font-stretch' 'ultra-expanded'](#) setting.

The [fontVariantCaps](#)<sup>p698</sup> attribute's allowed keywords are as follows:

## **normal**

None of the features listed below are enabled.

**small-caps**

Same as CSS ['font-variant-caps'](#) ['small-caps'](#) setting.

**all-small-caps**

Same as CSS ['font-variant-caps'](#) ['all-small-caps'](#) setting.

**petite-caps**

Same as CSS ['font-variant-caps'](#) ['petite-caps'](#) setting.

**all-petite-caps**

Same as CSS ['font-variant-caps'](#) ['all-petite-caps'](#) setting.

**unicase**

Same as CSS ['font-variant-caps'](#) ['unicase'](#) setting.

**titling-caps**

Same as CSS ['font-variant-caps'](#) ['titling-caps'](#) setting.

The [textRendering](#)<sup>p698</sup> attribute's allowed keywords are as follows:

**auto**

Same as 'auto' in [SVG text-rendering](#) property.

**optimizeSpeed**

Same as 'optimizeSpeed' in [SVG text-rendering](#) property.

**optimizeLegibility**

Same as 'optimizeLegibility' in [SVG text-rendering](#) property.

**geometricPrecision**

Same as 'geometricPrecision' in [SVG text-rendering](#) property.

The **text preparation algorithm** is as follows. It takes as input a string *text*, a [CanvasTextDrawingStyles](#)<sup>p685</sup> object *target*, and an optional length *maxWidth*. It returns an array of glyph shapes, each positioned on a common coordinate space, a *physical alignment* whose value is one of *left*, *right*, and *center*, and an [inline box](#). (Most callers of this algorithm ignore the *physical alignment* and the [inline box](#).)

1. If *maxWidth* was provided but is less than or equal to zero or equal to NaN, then return an empty array.
2. Replace all [ASCII whitespace](#) in *text* with U+0020 SPACE characters.
3. Let *font* be the current font of *target*, as given by that object's [font](#)<sup>p696</sup> attribute.
4. Apply the appropriate step from the following list to determine the value of *direction*:
  - ↪ If the **target object's** [direction](#)<sup>p697</sup> attribute has the value "[ltr](#)<sup>p699</sup>"  
Let *direction* be '[ltr](#)<sup>p160</sup>'.
  - ↪ If the **target object's** [direction](#)<sup>p697</sup> attribute has the value "[rtl](#)<sup>p699</sup>"  
Let *direction* be '[rtl](#)<sup>p160</sup>'.
  - ↪ If the **target object's** [font style source object](#)<sup>p695</sup> is an element  
Let *direction* be [the directionality](#)<sup>p160</sup> of the *target* object's [font style source object](#)<sup>p695</sup>.
  - ↪ If the **target object's** [font style source object](#)<sup>p695</sup> is a [Document](#)<sup>p130</sup> with a non-null [document element](#)  
Let *direction* be [the directionality](#)<sup>p160</sup> of the *target* object's [font style source object](#)<sup>p695</sup>'s [document element](#).
  - ↪ Otherwise  
Let *direction* be '[ltr](#)<sup>p160</sup>'.
5. Form a hypothetical infinitely-wide CSS [line box](#) containing a single [inline box](#) containing the text *text*, with its CSS properties set as follows:

Property	Source
<a href="#">'direction'</a>	<i>direction</i>

Property	Source
'font'	<i>font</i>
'font-kerning'	target's <a href="#">fontKerning</a> <sup>p697</sup>
'font-stretch'	target's <a href="#">fontStretch</a> <sup>p697</sup>
'font-variant-caps'	target's <a href="#">fontVariantCaps</a> <sup>p698</sup>
'letter-spacing'	target's <a href="#">letter spacing</a> <sup>p697</sup>
SVG <i>text-rendering</i>	target's <a href="#">textRendering</a> <sup>p698</sup>
'white-space'	'pre'
'word-spacing'	target's <a href="#">word spacing</a> <sup>p697</sup>

and with all other properties set to their initial values.

- If *maxWidth* was provided and the hypothetical width of the [inline box](#) in the hypothetical [line box](#) is greater than *maxWidth* [CSS pixels](#), then change *font* to have a more condensed font (if one is available or if a reasonably readable one can be synthesized by applying a horizontal scale factor to the font) or a smaller font, and return to the previous step.
- The *anchor point* is a point on the [inline box](#), and the *physical alignment* is one of the values *left*, *right*, and *center*. These variables are determined by the [textAlign](#)<sup>p697</sup> and [textBaseline](#)<sup>p697</sup> values as follows:

Horizontal position:

**If [textAlign](#)<sup>p697</sup> is [left](#)<sup>p698</sup>**

**If [textAlign](#)<sup>p697</sup> is [start](#)<sup>p698</sup> and *direction* is 'ltr'**

**If [textAlign](#)<sup>p697</sup> is [end](#)<sup>p698</sup> and *direction* is 'rtl'**

Let the *anchor point*'s horizontal position be the left edge of the [inline box](#), and let *physical alignment* be *left*.

**If [textAlign](#)<sup>p697</sup> is [right](#)<sup>p698</sup>**

**If [textAlign](#)<sup>p697</sup> is [end](#)<sup>p698</sup> and *direction* is 'ltr'**

**If [textAlign](#)<sup>p697</sup> is [start](#)<sup>p698</sup> and *direction* is 'rtl'**

Let the *anchor point*'s horizontal position be the right edge of the [inline box](#), and let *physical alignment* be *right*.

**If [textAlign](#)<sup>p697</sup> is [center](#)<sup>p698</sup>**

Let the *anchor point*'s horizontal position be half way between the left and right edges of the [inline box](#), and let *physical alignment* be *center*.

Vertical position:

**If [textBaseline](#)<sup>p697</sup> is [top](#)<sup>p698</sup>**

Let the *anchor point*'s vertical position be the top of the em box of the [first available font](#) of the [inline box](#).

**If [textBaseline](#)<sup>p697</sup> is [hanging](#)<sup>p698</sup>**

Let the *anchor point*'s vertical position be the [hanging baseline](#) of the [first available font](#) of the [inline box](#).

**If [textBaseline](#)<sup>p697</sup> is [middle](#)<sup>p698</sup>**

Let the *anchor point*'s vertical position be half way between the bottom and the top of the em box of the [first available font](#) of the [inline box](#).

**If [textBaseline](#)<sup>p697</sup> is [alphabetic](#)<sup>p698</sup>**

Let the *anchor point*'s vertical position be the [alphabetic baseline](#) of the [first available font](#) of the [inline box](#).

**If [textBaseline](#)<sup>p697</sup> is [ideographic](#)<sup>p699</sup>**

Let the *anchor point*'s vertical position be the [ideographic-under baseline](#) of the [first available font](#) of the [inline box](#).

**If [textBaseline](#)<sup>p697</sup> is [bottom](#)<sup>p699</sup>**

Let the *anchor point*'s vertical position be the bottom of the em box of the [first available font](#) of the [inline box](#).

- Let *result* be an array constructed by iterating over each glyph in the [inline box](#) from left to right (if any), adding to the array, for each glyph, the shape of the glyph as it is in the [inline box](#), positioned on a coordinate space using [CSS pixels](#) with its origin at the *anchor point*.
- Return *result*, *physical alignment*, and the inline box.

#### 4.12.5.1.5 Building paths <sup>§p702</sup><sub>2</sub>

Objects that implement the [CanvasPath<sup>p685</sup>](#) interface have a [path<sup>p702</sup>](#). A **path** has a list of zero or more subpaths. Each subpath consists of a list of one or more points, connected by straight or curved **line segments**, and a flag indicating whether the subpath is closed or not. A closed subpath is one where the last point of the subpath is connected to the first point of the subpath by a straight line. Subpaths with only one point are ignored when painting the path.

[Paths<sup>p702</sup>](#) have a **need new subpath** flag. When this flag is set, certain APIs create a new subpath rather than extending the previous one. When a [path<sup>p702</sup>](#) is created, its [need new subpath<sup>p702</sup>](#) flag must be set.

When an object implementing the [CanvasPath<sup>p685</sup>](#) interface is created, its [path<sup>p702</sup>](#) must be initialized to zero subpaths.

For web developers (non-normative)

`context.moveTop784(x, y)`

`path.moveTop784(x, y)`

Creates a new subpath with the given point.

`context.closePathp785()`

`path.closePathp785()`

Marks the current subpath as closed, and starts a new subpath with a point the same as the start and end of the newly closed subpath.

`context.lineTop785(x, y)`

`path.lineTop785(x, y)`

Adds the given point to the current subpath, connected to the previous one by a straight line.

`context.quadraticCurveTop785(cpx, cpy, x, y)`

`path.quadraticCurveTop785(cpx, cpy, x, y)`

Adds the given point to the current subpath, connected to the previous one by a quadratic Bézier curve with the given control point.

`context.bezierCurveTop785(cp1x, cp1y, cp2x, cp2y, x, y)`

`path.bezierCurveTop785(cp1x, cp1y, cp2x, cp2y, x, y)`

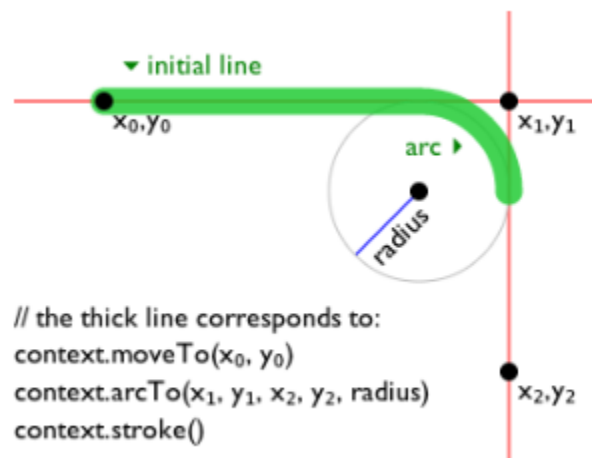

Adds the given point to the current subpath, connected to the previous one by a cubic Bézier curve with the given control points.

`context.arcTop785(x1, y1, x2, y2, radius)`

`path.arcTop785(x1, y1, x2, y2, radius)`

Adds an arc with the given control points and radius to the current subpath, connected to the previous point by a straight line.

Throws an ["IndexSizeError" DOMException](#) if the given radius is negative.

**`context.arcp706(x, y, radius, startAngle, endAngle [, counterclockwise ])`**

**`path.arcp706(x, y, radius, startAngle, endAngle [, counterclockwise ])`**

Adds points to the subpath such that the arc described by the circumference of the circle described by the arguments, starting at the given start angle and ending at the given end angle, going in the given direction (defaulting to clockwise), is added to the path, connected to the previous point by a straight line.

Throws an ["IndexSizeError" DOMException](#) if the given radius is negative.

**`context.ellipsep706(x, y, radiusX, radiusY, rotation, startAngle, endAngle [, counterclockwise])`**

**`path.ellipsep706(x, y, radiusX, radiusY, rotation, startAngle, endAngle [, counterclockwise])`**

Adds points to the subpath such that the arc described by the circumference of the ellipse described by the arguments, starting at the given start angle and ending at the given end angle, going in the given direction (defaulting to clockwise), is added to the path, connected to the previous point by a straight line.

Throws an ["IndexSizeError" DOMException](#) if the given radius is negative.

**`context.rectp706(x, y, w, h)`**

**`path.rectp706(x, y, w, h)`**

Adds a new closed subpath to the path, representing the given rectangle.

**`context.roundRectp707(x, y, w, h, radii)`**

**`path.roundRectp707(x, y, w, h, radii)`**

Adds a new closed subpath to the path representing the given rounded rectangle. *radii* is either a list of radii or a single radius representing the corners of the rectangle in pixels. If a list is provided, the number and order of these radii function in the same way as the CSS ['border-radius'](#) property. A single radius behaves the same way as a list with a single element.

If *w* and *h* are both greater than or equal to 0, or if both are smaller than 0, then the path is drawn clockwise. Otherwise, it is drawn counterclockwise.

When *w* is negative, the rounded rectangle is flipped horizontally, which means that the radius values that normally apply to the left corners are used on the right and vice versa. Similarly, when *h* is negative, the rounded rect is flipped vertically.

When a value *r* in *radii* is a number, the corresponding corner(s) are drawn as circular arcs of radius *r*.

When a value *r* in *radii* is an object with { *x*, *y* } properties, the corresponding corner(s) are drawn as elliptical arcs whose *x* and *y* radii are equal to *r.x* and *r.y*, respectively.

When the sum of the *radii* of two corners of the same edge is greater than the length of the edge, all the *radii* of the rounded rectangle are scaled by a factor of length / (*r1* + *r2*). If multiple edges have this property, the scale factor of the edge with the smallest scale factor is used. This is consistent with CSS behavior.

Throws a [RangeError](#) if *radii* is a list whose size is not one, two, three, or four.

Throws a [RangeError](#) if a value in *radii* is a negative number, or is an { *x*, *y* } object whose *x* or *y* properties are negative numbers.

The following methods allow authors to manipulate the [paths<sup>p702</sup>](#) of objects implementing the [CanvasPath<sup>p685</sup>](#) interface.

For objects implementing the [CanvasDrawPath<sup>p683</sup>](#) and [CanvasTransform<sup>p682</sup>](#) interfaces, the points passed to the methods, and the resulting lines added to [current default path<sup>p719</sup>](#) by these methods, must be transformed according to the [current transformation matrix<sup>p709</sup>](#) before being added to the path.

The [moveTo\(\*x\*, \*y\*\)](#) method, when invoked, must run these steps:

1. If either of the arguments are infinite or NaN, then return.

2. Create a new subpath with the specified point as its first (and only) point.

When the user agent is to **ensure there is a subpath** for a coordinate (x, y) on a [path](#)<sup>p702</sup>, the user agent must check to see if the [path](#)<sup>p702</sup> has its [need new subpath](#)<sup>p702</sup> flag set. If it does, then the user agent must create a new subpath with the point (x, y) as its first (and only) point, as if the [moveTo\(\)](#)<sup>p704</sup> method had been called, and must then unset the [path](#)<sup>p702</sup>'s [need new subpath](#)<sup>p702</sup> flag.

The **closePath()** method, when invoked, must do nothing if the object's path has no subpaths. Otherwise, it must mark the last subpath as closed, create a new subpath whose first point is the same as the previous subpath's first point, and finally add this new subpath to the path.

#### Note

*If the last subpath had more than one point in its list of points, then this is equivalent to adding a straight line connecting the last point back to the first point of the last subpath, thus "closing" the subpath.*

New points and the lines connecting them are added to subpaths using the methods described below. In all cases, the methods only modify the last subpath in the object's path.

The **lineTo(x, y)** method, when invoked, must run these steps:

1. If either of the arguments are infinite or NaN, then return.
2. If the object's path has no subpaths, then [ensure there is a subpath](#)<sup>p705</sup> for (x, y).
3. Otherwise, connect the last point in the subpath to the given point (x, y) using a straight line, and then add the given point (x, y) to the subpath.

The **quadraticCurveTo(cpx, cpy, x, y)** method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. [Ensure there is a subpath](#)<sup>p705</sup> for (cpx, cpy)
3. Connect the last point in the subpath to the given point (x, y) using a quadratic Bézier curve with control point (cpx, cpy). [\[BEZIER\]](#)<sup>p1475</sup>
4. Add the given point (x, y) to the subpath.

The **bezierCurveTo(cp1x, cp1y, cp2x, cp2y, x, y)** method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. [Ensure there is a subpath](#)<sup>p705</sup> for (cp1x, cp1y).
3. Connect the last point in the subpath to the given point (x, y) using a cubic Bézier curve with control points (cp1x, cp1y) and (cp2x, cp2y). [\[BEZIER\]](#)<sup>p1475</sup>
4. Add the point (x, y) to the subpath.

The **arcTo(x1, y1, x2, y2, radius)** method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. [Ensure there is a subpath](#)<sup>p705</sup> for (x1, y1).
3. If *radius* is negative, then throw an ["IndexSizeError" DOMException](#).
4. Let the point (x0, y0) be the last point in the subpath, transformed by the inverse of the [current transformation matrix](#)<sup>p709</sup> (so that it is in the same coordinate system as the points passed to the method).
5. If the point (x0, y0) is equal to the point (x1, y1), or if the point (x1, y1) is equal to the point (x2, y2), or if *radius* is zero, then add the point (x1, y1) to the subpath, and connect that point to the previous point (x0, y0) by a straight line.
6. Otherwise, if the points (x0, y0), (x1, y1), and (x2, y2) all lie on a single straight line, then add the point (x1, y1) to the subpath, and connect that point to the previous point (x0, y0) by a straight line.

7. Otherwise, let *The Arc* be the shortest arc given by circumference of the circle that has radius *radius*, and that has one point tangent to the half-infinite line that crosses the point (*x0*, *y0*) and ends at the point (*x1*, *y1*), and that has a different point tangent to the half-infinite line that ends at the point (*x1*, *y1*) and crosses the point (*x2*, *y2*). The points at which this circle touches these two lines are called the start and end tangent points respectively. Connect the point (*x0*, *y0*) to the start tangent point by a straight line, adding the start tangent point to the subpath, and then connect the start tangent point to the end tangent point by *The Arc*, adding the end tangent point to the subpath.

The **arc(*x*, *y*, *radius*, *startAngle*, *endAngle*, *counterclockwise*)** method, when invoked, must run the [ellipse method steps<sup>p706</sup>](#) with this, *x*, *y*, *radius*, *radius*, 0, *startAngle*, *endAngle*, and *counterclockwise*.

#### Note

This makes it equivalent to **ellipse()<sup>p706</sup>** except that both radii are equal and rotation is 0.

The **ellipse(*x*, *y*, *radiusX*, *radiusY*, *rotation*, *startAngle*, *endAngle*, *counterclockwise*)** method, when invoked, must run the [ellipse method steps<sup>p706</sup>](#) with this, *x*, *y*, *radiusX*, *radiusY*, *rotation*, *startAngle*, *endAngle*, and *counterclockwise*.

The **determine the point on an ellipse steps**, given *ellipse*, and *angle*, are:

1. Let *eccentricCircle* be the circle that shares its origin with *ellipse*, with a radius equal to the semi-major axis of *ellipse*.
2. Let *outerPoint* be the point on *eccentricCircle*'s circumference at *angle* measured in radians clockwise from *ellipse*'s semi-major axis.
3. Let *chord* be the line perpendicular to *ellipse*'s major axis between this axis and *outerPoint*.
4. Return the point on *chord* that crosses *ellipse*'s circumference.

The **ellipse method steps**, given *canvasPath*, *x*, *y*, *radiusX*, *radiusY*, *rotation*, *startAngle*, *endAngle*, and *counterclockwise*, are:

1. If any of the arguments are infinite or NaN, then return.
2. If either *radiusX* or *radiusY* are negative, then throw an **"IndexSizeError" DOMException**.
3. If *canvasPath*'s path has any subpaths, then add a straight line from the last point in the subpath to the start point of the arc.
4. Add the start and end points of the arc to the subpath, and connect them with an arc. The arc and its start and end points are defined as follows:

Consider an ellipse that has its origin at (*x*, *y*), that has a major-axis radius *radiusX* and a minor-axis radius *radiusY*, and that is rotated about its origin such that its semi-major axis is inclined *rotation* radians clockwise from the x-axis.

If *counterclockwise* is false and *endAngle* – *startAngle* is greater than or equal to  $2\pi$ , or, if *counterclockwise* is true and *startAngle* – *endAngle* is greater than or equal to  $2\pi$ , then the arc is the whole circumference of this ellipse, and both the start point and the end point are the result of running the [determine the point on an ellipse steps<sup>p706</sup>](#) given this ellipse and *startAngle*.

Otherwise, the start point is the result of running the [determine the point on an ellipse steps<sup>p706</sup>](#) given this ellipse and *startAngle*, the end point is the result of running the [determine the point on an ellipse steps<sup>p706</sup>](#) given this ellipse and *endAngle*, and the arc is the path along the circumference of this ellipse from the start point to the end point, going counterclockwise if *counterclockwise* is true, and clockwise otherwise. Since the points are on the ellipse, as opposed to being simply angles from zero, the arc can never cover an angle greater than  $2\pi$  radians.

#### Note

Even if the arc covers the entire circumference of the ellipse and there are no other points in the subpath, the path is not closed unless the **closePath()<sup>p705</sup>** method is appropriately invoked.

The **rect(*x*, *y*, *w*, *h*)** method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. Create a new subpath containing just the four points (*x*, *y*), (*x*+*w*, *y*), (*x*+*w*, *y*+*h*), (*x*, *y*+*h*), in that order, with those four points connected by straight lines.

3. Mark the subpath as closed.
4. Create a new subpath with the point (x, y) as the only point in the subpath.

The **roundRect(x, y, w, h, radii)** method steps are:

1. If any of x, y, w, or h are infinite or NaN, then return.
2. If radii is an [unrestricted double](#) or [DOMPointInit](#), then set radii to « radii ».
3. If radii is not a list of size one, two, three, or four, then throw a [RangeError](#).
4. Let *normalizedRadii* be an empty list.
5. For each *radius* of radii:
  1. If *radius* is a [DOMPointInit](#):
    1. If *radius*["x<sup>p67</sup>"] or *radius*["y<sup>p67</sup>"] is infinite or NaN, then return.
    2. If *radius*["x<sup>p67</sup>"] or *radius*["y<sup>p67</sup>"] is negative, then throw a [RangeError](#).
    3. Otherwise, append *radius* to *normalizedRadii*.
  2. If *radius* is a [unrestricted double](#):
    1. If *radius* is infinite or NaN, then return.
    2. If *radius* is negative, then throw a [RangeError](#).
    3. Otherwise, append « [ "x<sup>p67</sup>" → *radius*, "y<sup>p67</sup>" → *radius* ] » to *normalizedRadii*.
6. Let *upperLeft*, *upperRight*, *lowerRight*, and *lowerLeft* be null.
7. If *normalizedRadii*'s size is 4, then set *upperLeft* to *normalizedRadii*[0], set *upperRight* to *normalizedRadii*[1], set *lowerRight* to *normalizedRadii*[2], and set *lowerLeft* to *normalizedRadii*[3].
8. If *normalizedRadii*'s size is 3, then set *upperLeft* to *normalizedRadii*[0], set *upperRight* and *lowerLeft* to *normalizedRadii*[1], and set *lowerRight* to *normalizedRadii*[2].
9. If *normalizedRadii*'s size is 2, then set *upperLeft* and *lowerRight* to *normalizedRadii*[0] and set *upperRight* and *lowerLeft* to *normalizedRadii*[1].
10. If *normalizedRadii*'s size is 1, then set *upperLeft*, *upperRight*, *lowerRight*, and *lowerLeft* to *normalizedRadii*[0].
11. Corner curves must not overlap. Scale all radii to prevent this:
  1. Let *top* be *upperLeft*["x<sup>p67</sup>"] + *upperRight*["x<sup>p67</sup>"].
  2. Let *right* be *upperRight*["y<sup>p67</sup>"] + *lowerRight*["y<sup>p67</sup>"].
  3. Let *bottom* be *lowerRight*["x<sup>p67</sup>"] + *lowerLeft*["x<sup>p67</sup>"].
  4. Let *left* be *upperLeft*["y<sup>p67</sup>"] + *lowerLeft*["y<sup>p67</sup>"].
  5. Let *scale* be the minimum value of the ratios *w* / *top*, *h* / *right*, *w* / *bottom*, *h* / *left*.
  6. If *scale* is less than 1, then set the [x<sup>p67</sup>](#) and [y<sup>p67</sup>](#) members of *upperLeft*, *upperRight*, *lowerLeft*, and *lowerRight* to their current values multiplied by *scale*.
12. Create a new subpath:
  1. Move to the point (x + *upperLeft*["x<sup>p67</sup>"], y).
  2. Draw a straight line to the point (x + w - *upperRight*["x<sup>p67</sup>"], y).
  3. Draw an arc to the point (x + w, y + *upperRight*["y<sup>p67</sup>"]).
  4. Draw a straight line to the point (x + w, y + h - *lowerRight*["y<sup>p67</sup>"]).
  5. Draw an arc to the point (x + w - *lowerRight*["x<sup>p67</sup>"], y + h).
  6. Draw a straight line to the point (x + *lowerLeft*["x<sup>p67</sup>"], y + h).

7. Draw an arc to the point  $(x, y + h - \text{lowerLeft}["y_{p67}"])$ .
8. Draw a straight line to the point  $(x, y + \text{upperLeft}["y_{p67}"])$ .
9. Draw an arc to the point  $(x + \text{upperLeft}["x_{p67}"], y)$ .
13. Mark the subpath as closed.
14. Create a new subpath with the point  $(x, y)$  as the only point in the subpath.

#### Note

*This is designed to behave similarly to the CSS ['border-radius'](#) property.*

#### 4.12.5.1.6 [Path2D<sup>p686</sup>](#) objects <sup>§<sup>p70</sup><sub>8</sub></sup>

[Path2D<sup>p686</sup>](#) objects can be used to declare paths that are then later used on objects implementing the [CanvasDrawPath<sup>p683</sup>](#) interface. In addition to many of the APIs described in earlier sections, [Path2D<sup>p686</sup>](#) objects have methods to combine paths, and to add text to paths.

#### For web developers (non-normative)

**`path = new Path2Dp708()`**

Creates a new empty [Path2D<sup>p686</sup>](#) object.

**`path = new Path2Dp708(path)`**

When *path* is a [Path2D<sup>p686</sup>](#) object, returns a copy.

When *path* is a string, creates the path described by the argument, interpreted as SVG path data. [\[SVG\]<sup>p1482</sup>](#)

**`path.addPathp708(path [, transform ])`**

Adds to the path the path given by the argument.

The [Path2D\(\*path\*\)](#) constructor, when invoked, must run these steps:

1. Let *output* be a new [Path2D<sup>p686</sup>](#) object.
2. If *path* is not given, then return *output*.
3. If *path* is a [Path2D<sup>p686</sup>](#) object, then add all subpaths of *path* to *output* and return *output*. (In other words, it returns a copy of the argument.)
4. Let *svgPath* be the result of parsing and interpreting *path* according to SVG 2's rules for path data. [\[SVG\]<sup>p1482</sup>](#)

#### Note

*The resulting path could be empty. SVG defines error handling rules for parsing and applying path data.*

5. Let  $(x, y)$  be the last point in *svgPath*.
6. Add all the subpaths, if any, from *svgPath* to *output*.
7. Create a new subpath in *output* with  $(x, y)$  as the only point in the subpath.
8. Return *output*.

The [addPath\(\*path\*, \*transform\*\)](#) method, when invoked on a [Path2D<sup>p686</sup>](#) object *a*, must run these steps:

1. If the [Path2D<sup>p686</sup>](#) object *path* has no subpaths, then return.
2. Let *matrix* be the result of [creating a DOMMatrix from the 2D dictionary](#) *transform*.
3. If one or more of *matrix*'s [m11 element](#), [m12 element](#), [m21 element](#), [m22 element](#), [m41 element](#), or [m42 element](#) are infinite or NaN, then return.
4. Create a copy of all the subpaths in *path*. Let this copy be known as *c*.
5. Transform all the coordinates and lines in *c* by the transform matrix *matrix*.

6. Let (x, y) be the last point in the last subpath of c.
7. Add all the subpaths in c to a.
8. Create a new subpath in a with (x, y) as the only point in the subpath.

#### 4.12.5.1.7 Transformations §<sup>p70</sup><sub>9</sub>

Objects that implement the [CanvasTransform<sup>p682</sup>](#) interface have a **current transformation matrix**, as well as methods (described in this section) to manipulate it. When an object implementing the [CanvasTransform<sup>p682</sup>](#) interface is created, its transformation matrix must be initialized to the identity matrix.

The [current transformation matrix<sup>p709</sup>](#) is applied to coordinates when creating the [current default path<sup>p719</sup>](#), and when painting text, shapes, and [Path2D<sup>p686</sup>](#) objects, on objects implementing the [CanvasTransform<sup>p682</sup>](#) interface.

The transformations must be performed in reverse order.

#### Note

*For instance, if a scale transformation that doubles the width is applied to the canvas, followed by a rotation transformation that rotates drawing operations by a quarter turn, and a rectangle twice as wide as it is tall is then drawn on the canvas, the actual result will be a square.*

#### For web developers (non-normative)

**context.scale<sup>p709</sup>(x, y)**

Changes the [current transformation matrix<sup>p709</sup>](#) to apply a scaling transformation with the given characteristics.

**context.rotate<sup>p709</sup>(angle)**

Changes the [current transformation matrix<sup>p709</sup>](#) to apply a rotation transformation with the given characteristics. The angle is in radians.

**context.translate<sup>p710</sup>(x, y)**

Changes the [current transformation matrix<sup>p709</sup>](#) to apply a translation transformation with the given characteristics.

**context.transform<sup>p710</sup>(a, b, c, d, e, f)**

Changes the [current transformation matrix<sup>p709</sup>](#) to apply the matrix given by the arguments as described below.

**matrix = context.getTransform<sup>p710</sup>()**

Returns a copy of the [current transformation matrix<sup>p709</sup>](#), as a newly created [DOMMatrix](#) object.

**context.setTransform<sup>p710</sup>(a, b, c, d, e, f)**

Changes the [current transformation matrix<sup>p709</sup>](#) to the matrix given by the arguments as described below.

**context.setTransform<sup>p710</sup>(transform)**

Changes the [current transformation matrix<sup>p709</sup>](#) to the matrix represented by the passed [DOMMatrix2DInit](#) dictionary.

**context.resetTransform<sup>p710</sup>()**

Changes the [current transformation matrix<sup>p709</sup>](#) to the identity matrix.

The **scale(x, y)** method, when invoked, must run these steps:

1. If either of the arguments are infinite or NaN, then return.
2. Add the scaling transformation described by the arguments to the [current transformation matrix<sup>p709</sup>](#). The x argument represents the scale factor in the horizontal direction and the y argument represents the scale factor in the vertical direction. The factors are multiples.

The **rotate(angle)** method, when invoked, must run these steps:

1. If *angle* is infinite or NaN, then return.
2. Add the rotation transformation described by the argument to the [current transformation matrix<sup>p709</sup>](#). The *angle* argument represents a clockwise rotation angle expressed in radians.

The **translate(x, y)** method, when invoked, must run these steps:

1. If either of the arguments are infinite or NaN, then return.
2. Add the translation transformation described by the arguments to the [current transformation matrix](#)<sup>p709</sup>. The x argument represents the translation distance in the horizontal direction and the y argument represents the translation distance in the vertical direction. The arguments are in coordinate space units.

The **transform(a, b, c, d, e, f)** method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. Replace the [current transformation matrix](#)<sup>p709</sup> with the result of [multiplying](#) the [current transformation matrix](#)<sup>p709</sup> with the matrix described by:

$$\begin{bmatrix} a & c & e \\ b & d & f \\ 0 & 0 & 1 \end{bmatrix}$$

#### Note

*The arguments a, b, c, d, e, and f are sometimes called m11, m12, m21, m22, dx, and dy or m11, m21, m12, m22, dx, and dy. Care ought to be taken in particular with the order of the second and third arguments (b and c) as their order varies from API to API and APIs sometimes use the notation m12/m21 and sometimes m21/m12 for those positions.*

The **getTransform()** method, when invoked, must return a newly created **DOMMatrix** representing a copy of the [current transformation matrix](#)<sup>p709</sup> matrix of the context.

#### Note

*This returned object is not live, so updating it will not affect the [current transformation matrix](#)<sup>p709</sup>, and updating the [current transformation matrix](#)<sup>p709</sup> will not affect an already returned **DOMMatrix**.*

The **setTransform(a, b, c, d, e, f)** method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. Reset the [current transformation matrix](#)<sup>p709</sup> to the matrix described by:

$$\begin{bmatrix} a & c & e \\ b & d & f \\ 0 & 0 & 1 \end{bmatrix}$$

The **setTransform(transform)** method, when invoked, must run these steps:

1. Let *matrix* be the result of [creating a DOMMatrix from the 2D dictionary transform](#).
2. If one or more of *matrix*'s [m11 element](#), [m12 element](#), [m21 element](#), [m22 element](#), [m41 element](#), or [m42 element](#) are infinite or NaN, then return.
3. Reset the [current transformation matrix](#)<sup>p709</sup> to *matrix*.

The **resetTransform()** method, when invoked, must reset the [current transformation matrix](#)<sup>p709</sup> to the identity matrix.

#### Note

*Given a matrix of the form created by the [transform\(\)](#)<sup>p710</sup> and [setTransform\(\)](#)<sup>p710</sup> methods, i.e.,*

$$\begin{bmatrix} a & c & e \\ b & d & f \\ 0 & 0 & 1 \end{bmatrix}$$

*the resulting transformed coordinates after transform matrix multiplication will be*

$$\begin{aligned} x_{new} &= a x + c y + e \\ y_{new} &= b x + d y + f \end{aligned}$$

#### 4.12.5.1.8 Image sources for 2D rendering contexts <sup>§<sup>p71</sup></sup><sub>1</sub>

Some methods on the [CanvasDrawImage](#)<sup>p684</sup> and [CanvasFillStrokeStyles](#)<sup>p683</sup> interfaces take the union type [CanvasImageSource](#)<sup>p682</sup> as an argument.

This union type allows objects implementing any of the following interfaces to be used as image sources:

- [HTML0rSVGImageElement](#)<sup>p682</sup> ([img](#)<sup>p346</sup> or [SVG image](#) elements)
- [HTMLVideoElement](#)<sup>p497</sup> ([video](#)<sup>p496</sup> elements)
- [HTMLCanvasElement](#)<sup>p677</sup> ([canvas](#)<sup>p677</sup> elements)
- [OffscreenCanvas](#)<sup>p741</sup>
- [ImageBitmap](#)<sup>p1181</sup>
- [VideoFrame](#)

#### Note

Although not formally specified as such, [SVG image](#) elements are expected to be implemented nearly identical to [img](#)<sup>p346</sup> elements. That is, [SVG image](#) elements share the fundamental concepts and features of [img](#)<sup>p346</sup> elements.

#### Note

The [ImageBitmap](#)<sup>p1181</sup> interface can be created from a number of other image-representing types, including [ImageData](#)<sup>p686</sup>.

To **check the usability of the *image* argument**, where *image* is a [CanvasImageSource](#)<sup>p682</sup> object, run these steps:

1. Switch on *image*:

↪ [HTML0rSVGImageElement](#)<sup>p682</sup>

If *image*'s [current request](#)<sup>p363</sup>'s [state](#)<sup>p363</sup> is [broken](#)<sup>p364</sup>, then throw an ["InvalidStateError"](#) [DOMException](#).

If *image* is not [fully decodable](#)<sup>p364</sup>, then return *bad*.

If *image* has a [natural width](#) or [natural height](#) (or both) equal to zero, then return *bad*.

↪ [HTMLVideoElement](#)<sup>p497</sup>

If *image*'s [readyState](#)<sup>p435</sup> attribute is either [HAVE\\_NOTHING](#)<sup>p433</sup> or [HAVE\\_METADATA](#)<sup>p433</sup>, then return *bad*.

↪ [HTMLCanvasElement](#)<sup>p677</sup>

↪ [OffscreenCanvas](#)<sup>p741</sup>

If *image* has either a horizontal dimension or a vertical dimension equal to zero, then throw an ["InvalidStateError"](#) [DOMException](#).

↪ [ImageBitmap](#)<sup>p1181</sup>

↪ [VideoFrame](#)

If *image*'s [\[\[Detached\]\]](#)<sup>p118</sup> internal slot value is set to true, then throw an ["InvalidStateError"](#) [DOMException](#).

2. Return *good*.

When a [CanvasImageSource](#)<sup>p682</sup> object represents an [HTML0rSVGImageElement](#)<sup>p682</sup>, the element's image must be used as the source image.

Specifically, when a [CanvasImageSource](#)<sup>p682</sup> object represents an animated image in an [HTML0rSVGImageElement](#)<sup>p682</sup>, the user agent must use the default image of the animation (the one that the format defines is to be used when animation is not supported or is disabled), or, if there is no such image, the first frame of the animation, when rendering the image for [CanvasRenderingContext2D](#)<sup>p682</sup> APIs.

When a [CanvasImageSource](#)<sup>p682</sup> object represents an [HTMLVideoElement](#)<sup>p497</sup>, then the frame at the [current playback position](#)<sup>p432</sup> when the method with the argument is invoked must be used as the source image when rendering the image for [CanvasRenderingContext2D](#)<sup>p682</sup> APIs, and the source image's dimensions must be the [natural width](#)<sup>p409</sup> and [natural height](#)<sup>p409</sup> of the [media resource](#)<sup>p415</sup> (i.e., after any aspect-ratio correction has been applied).

When a [CanvasImageSource](#)<sup>p682</sup> object represents an [HTMLCanvasElement](#)<sup>p677</sup>, the element's bitmap must be used as the source image.

When a [CanvasImageSource](#)<sup>p682</sup> object represents an element that is [being rendered](#)<sup>p1388</sup> and that element has been resized, the original image data of the source image must be used, not the image as it is rendered (e.g. [width](#)<sup>p477</sup> and [height](#)<sup>p477</sup> attributes on the source element have no effect on how the object is interpreted when rendering the image for [CanvasRenderingContext2D](#)<sup>p682</sup> APIs).

When a [CanvasImageSource](#)<sup>p682</sup> object represents an [ImageBitmap](#)<sup>p1181</sup>, the object's bitmap image data must be used as the source image.

When a [CanvasImageSource](#)<sup>p682</sup> object represents an [OffscreenCanvas](#)<sup>p741</sup>, the object's bitmap must be used as the source image.

When a [CanvasImageSource](#)<sup>p682</sup> object represents a [VideoFrame](#), the object's pixel data must be used as the source image, and the source image's dimensions must be the object's [\[\[display width\]\]](#) and [\[\[display height\]\]](#).

An object *image* is **not origin-clean** if, switching on *image*'s type:

- ↪ [HTMLImageElement](#)<sup>p682</sup>  
*image*'s [current request](#)<sup>p363</sup>'s [image data](#)<sup>p363</sup> is [CORS-cross-origin](#)<sup>p98</sup>.
- ↪ [HTMLVideoElement](#)<sup>p407</sup>  
*image*'s [media data](#)<sup>p415</sup> is [CORS-cross-origin](#)<sup>p98</sup>.
- ↪ [HTMLCanvasElement](#)<sup>p677</sup>
- ↪ [ImageBitmap](#)<sup>p1181</sup>
- ↪ [OffscreenCanvas](#)<sup>p741</sup>  
*image*'s bitmap's [origin-clean](#)<sup>p678</sup> flag is false.

#### 4.12.5.1.9 Fill and stroke styles <sup>§<sup>p71</sup><sub>2</sub></sup>

For web developers (non-normative)

**`context.fillStyle`**<sup>p712</sup> [ = *value* ]

Returns the current style used for filling shapes.

Can be set, to change the [fill style](#)<sup>p712</sup>.

The style can be either a string containing a CSS color, or a [CanvasGradient](#)<sup>p685</sup> or [CanvasPattern](#)<sup>p685</sup> object. Invalid values are ignored.

**`context.strokeStyle`**<sup>p713</sup> [ = *value* ]

Returns the current style used for stroking shapes.

Can be set, to change the [stroke style](#)<sup>p712</sup>.

The style can be either a string containing a CSS color, or a [CanvasGradient](#)<sup>p685</sup> or [CanvasPattern](#)<sup>p685</sup> object. Invalid values are ignored.

Objects that implement the [CanvasFillStrokeStyles](#)<sup>p683</sup> interface have attributes and methods (defined in this section) that control how shapes are treated by the object.

Such objects have associated **fill style** and **stroke style** values, which are either CSS colors, [CanvasPattern](#)<sup>p685</sup>s, or [CanvasGradient](#)<sup>p685</sup>s. Initially, both must be the result of [parsing](#) the string `"#000000"`.

When the value is a CSS color, it must not be affected by the transformation matrix when used to draw on bitmaps.

#### Note

When set to a [CanvasPattern](#)<sup>p685</sup> or [CanvasGradient](#)<sup>p685</sup> object, changes made to the object after the assignment do affect subsequent stroking or filling of shapes.

The **fillStyle** getter steps are:

1. If [this](#)'s [fill style](#)<sup>p712</sup> is a CSS color, then return the [serialization](#) of that color with [HTML-compatible serialization requested](#).

2. Return [this's fill\\_style<sup>p712</sup>](#).

The [fillStyle<sup>p712</sup>](#) setter steps are:

1. If the given value is a string, then:
  1. Let *context* be [this's canvas<sup>p689</sup>](#) attribute's value, if that is an element; otherwise null.
  2. Let *parsedValue* be the result of [parsing](#) the given value with *context* if non-null.
  3. If *parsedValue* is failure, then return.
  4. Set [this's fill\\_style<sup>p712</sup>](#) to *parsedValue*.
  5. Return.
2. If the given value is a [CanvasPattern<sup>p685</sup>](#) object that is marked as [not origin-clean<sup>p715</sup>](#), then set [this's origin-clean<sup>p678</sup>](#) flag to false.
3. Set [this's fill\\_style<sup>p712</sup>](#) to the given value.

The [strokeStyle](#) getter steps are:

1. If [this's stroke\\_style<sup>p712</sup>](#) is a CSS color, then return the [serialization](#) of that color with [HTML-compatible serialization requested](#).
2. Return [this's stroke\\_style<sup>p712</sup>](#).

The [strokeStyle<sup>p713</sup>](#) setter steps are:

1. If the given value is a string, then:
  1. Let *context* be [this's canvas<sup>p689</sup>](#) attribute's value, if that is an element; otherwise null.
  2. Let *parsedValue* be the result of [parsing](#) the given value with *context* if non-null.
  3. If *parsedValue* is failure, then return.
  4. Set [this's stroke\\_style<sup>p712</sup>](#) to *parsedValue*.
  5. Return.
2. If the given value is a [CanvasPattern<sup>p685</sup>](#) object that is marked as [not origin-clean<sup>p715</sup>](#), then set [this's origin-clean<sup>p678</sup>](#) flag to false.
3. Set [this's stroke\\_style<sup>p712</sup>](#) to the given value.

There are three types of gradients, linear gradients, radial gradients, and conic gradients, represented by objects implementing the opaque [CanvasGradient<sup>p685</sup>](#) interface.

Once a gradient has been created (see below), stops are placed along it to define how the colors are distributed along the gradient. The color of the gradient at each stop is the color specified for that stop. Between each such stop, the colors and the alpha component must be linearly interpolated over the RGBA space without premultiplying the alpha value to find the color to use at that offset. Before the first stop, the color must be the color of the first stop. After the last stop, the color must be the color of the last stop. When there are no stops, the gradient is [transparent black](#).

For web developers (non-normative)

**[gradient.addColorStop<sup>p714</sup>\(offset, color\)](#)**

Adds a color stop with the given color to the gradient at the given offset. 0.0 is the offset at one end of the gradient, 1.0 is the offset at the other end.

Throws an ["IndexSizeError"](#) [DOMException](#) if the offset is out of range. Throws a ["SyntaxError"](#) [DOMException](#) if the color cannot be parsed.

**[gradient = context.createLinearGradient<sup>p714</sup>\(x0, y0, x1, y1\)](#)**

Returns a [CanvasGradient<sup>p685</sup>](#) object that represents a linear gradient that paints along the line given by the coordinates represented by the arguments.

**`gradient = context.createRadialGradient`**<sup>p714</sup>(`x0`, `y0`, `r0`, `x1`, `y1`, `r1`)

Returns a [CanvasGradient](#)<sup>p685</sup> object that represents a radial gradient that paints along the cone given by the circles represented by the arguments.

If either of the radii are negative, throws an ["IndexSizeError" DOMException](#) exception.

**`gradient = context.createConicGradient`**<sup>p715</sup>(`startAngle`, `x`, `y`)

Returns a [CanvasGradient](#)<sup>p685</sup> object that represents a conic gradient that paints clockwise along the rotation around the center represented by the arguments.

The **`addColorStop`**(`offset`, `color`) method on the [CanvasGradient](#)<sup>p685</sup>, when invoked, must run these steps:

1. If the `offset` is less than 0 or greater than 1, then throw an ["IndexSizeError" DOMException](#).
2. Let *parsed color* be the result of [parsing color](#).

**Note**

*No element is passed to the parser because [CanvasGradient](#)<sup>p685</sup> objects are [canvas](#)<sup>p677</sup>-neutral — a [CanvasGradient](#)<sup>p685</sup> object created by one [canvas](#)<sup>p677</sup> can be used by another, and there is therefore no way to know which is the "element in question" at the time that the color is specified.*

3. If *parsed color* is failure, throw a ["SyntaxError" DOMException](#).
4. Place a new stop on the gradient, at offset `offset` relative to the whole gradient, and with the color *parsed color*.

If multiple stops are added at the same offset on a gradient, then they must be placed in the order added, with the first one closest to the start of the gradient, and each subsequent one infinitesimally further along towards the end point (in effect causing all but the first and last stop added at each point to be ignored).

The **`createLinearGradient`**(`x0`, `y0`, `x1`, `y1`) method takes four arguments that represent the start point (`x0`, `y0`) and end point (`x1`, `y1`) of the gradient. The method, when invoked, must return a linear [CanvasGradient](#)<sup>p685</sup> initialized with the specified line.

Linear gradients must be rendered such that all points on a line perpendicular to the line that crosses the start and end points have the color at the point where those two lines cross (with the colors coming from the [interpolation and extrapolation](#)<sup>p713</sup> described above). The points in the linear gradient must be transformed as described by the [current transformation matrix](#)<sup>p709</sup> when rendering.

If `x0 = x1` and `y0 = y1`, then the linear gradient must paint nothing.

The **`createRadialGradient`**(`x0`, `y0`, `r0`, `x1`, `y1`, `r1`) method takes six arguments, the first three representing the start circle with origin (`x0`, `y0`) and radius `r0`, and the last three representing the end circle with origin (`x1`, `y1`) and radius `r1`. The values are in coordinate space units. If either of `r0` or `r1` are negative, then an ["IndexSizeError" DOMException](#) must be thrown. Otherwise, the method, when invoked, must return a radial [CanvasGradient](#)<sup>p685</sup> initialized with the two specified circles.

Radial gradients must be rendered by following these steps:

1. If `x0 = x1` and `y0 = y1` and `r0 = r1`, then the radial gradient must paint nothing. Return.
2. Let  $x(\omega) = (x1 - x0)\omega + x0$   
Let  $y(\omega) = (y1 - y0)\omega + y0$   
Let  $r(\omega) = (r1 - r0)\omega + r0$   
Let the color at  $\omega$  be the color at that position on the gradient (with the colors coming from the [interpolation and extrapolation](#)<sup>p713</sup> described above).
3. For all values of  $\omega$  where  $r(\omega) > 0$ , starting with the value of  $\omega$  nearest to positive infinity and ending with the value of  $\omega$  nearest to negative infinity, draw the circumference of the circle with radius  $r(\omega)$  at position ( $x(\omega)$ ,  $y(\omega)$ ), with the color at  $\omega$ , but only painting on the parts of the bitmap that have not yet been painted on by earlier circles in this step for this rendering of the gradient.

**Note**

*This effectively creates a cone, touched by the two circles defined in the creation of the gradient, with the part of the cone before the start circle (0.0) using the color of the first offset, the part of the cone after the end circle (1.0) using the color of the last*

offset, and areas outside the cone untouched by the gradient (transparent black).

The resulting radial gradient must then be transformed as described by the [current transformation matrix](#)<sup>p709</sup> when rendering.

The `createConicGradient(startAngle, x, y)` method takes three arguments, the first argument, *startAngle*, represents the angle in radians at which the gradient begins, and the last two arguments, (*x*, *y*), represent the center of the gradient in [CSS pixels](#). The method, when invoked, must return a conic [CanvasGradient](#)<sup>p685</sup> initialized with the specified center and angle.

It follows the same rendering rule as CSS '[conic-gradient](#)' and it is equivalent to CSS '[conic-gradient](#)(from *adjustedStartAngle*rad at *xpx ypx*, *angularColorStopList*)'. Here:

- *adjustedStartAngle* is given by *startAngle* +  $\pi/2$ ;
- *angularColorStopList* is given by the color stops that have been added to the [CanvasGradient](#)<sup>p685</sup> using [addColorStop\(\)](#)<sup>p714</sup>, with the color stop offsets interpreted as percentages.

Gradients must be painted only where the relevant stroking or filling effects requires that they be drawn.

Patterns are represented by objects implementing the opaque [CanvasPattern](#)<sup>p685</sup> interface.

#### For web developers (non-normative)

**`pattern = context.createPattern`**<sup>p715</sup>(*image*, *repetition*)

Returns a [CanvasPattern](#)<sup>p685</sup> object that uses the given image and repeats in the direction(s) given by the *repetition* argument.

The allowed values for *repetition* are `repeat` (both directions), `repeat-x` (horizontal only), `repeat-y` (vertical only), and `no-repeat` (neither). If the *repetition* argument is empty, the value `repeat` is used.

If the image isn't yet fully decoded, then nothing is drawn. If the image is a canvas with no data, throws an ["InvalidStateError" DOMException](#).

**`pattern.setTransform`**<sup>p715</sup>(*transform*)

Sets the transformation matrix that will be used when rendering the pattern during a fill or stroke painting operation.

The `createPattern(image, repetition)` method, when invoked, must run these steps:

1. Let *usability* be the result of [checking the usability of](#)<sup>p711</sup> *image*.
2. If *usability* is bad, then return null.
3. [Assert](#): *usability* is good.
4. If *repetition* is the empty string, then set it to `"repeat"`.
5. If *repetition* is not [identical to](#) one of `"repeat"`, `"repeat-x"`, `"repeat-y"`, or `"no-repeat"`, then throw a ["SyntaxError" DOMException](#).
6. Let *pattern* be a new [CanvasPattern](#)<sup>p685</sup> object with the image *image* and the repetition behavior given by *repetition*.
7. If *image* is [not origin-clean](#)<sup>p712</sup>, then mark *pattern* as **not origin-clean**.
8. Return *pattern*.

Modifying the *image* used when creating a [CanvasPattern](#)<sup>p685</sup> object after calling the [createPattern\(\)](#)<sup>p715</sup> method must not affect the pattern(s) rendered by the [CanvasPattern](#)<sup>p685</sup> object.

Patterns have a transformation matrix, which controls how the pattern is used when it is painted. Initially, a pattern's transformation matrix must be the identity matrix.

The `setTransform(transform)` method, when invoked, must run these steps:

1. Let *matrix* be the result of [creating a DOMMatrix from the 2D dictionary](#) *transform*.
2. If one or more of *matrix*'s [m11 element](#), [m12 element](#), [m21 element](#), [m22 element](#), [m41 element](#), or [m42 element](#) are infinite or NaN, then return.

3. Reset the pattern's transformation matrix to *matrix*.

When a pattern is to be rendered within an area, the user agent must run the following steps to determine what is rendered:

1. Create an infinite [transparent black](#) bitmap.
2. Place a copy of the image on the bitmap, anchored such that its top left corner is at the origin of the coordinate space, with one coordinate space unit per [CSS pixel](#) of the image, then place repeated copies of this image horizontally to the left and right, if the repetition behavior is "repeat-x", or vertically up and down, if the repetition behavior is "repeat-y", or in all four directions all over the bitmap, if the repetition behavior is "repeat".

If the original image data is a bitmap image, then the value painted at a point in the area of the repetitions is computed by filtering the original image data. When scaling up, if the [imageSmoothingEnabled](#)<sup>p731</sup> attribute is set to false, then the image must be rendered using nearest-neighbor interpolation. Otherwise, the user agent may use any filtering algorithm (for example bilinear interpolation or nearest-neighbor). User agents which support multiple filtering algorithms may use the value of the [imageSmoothingQuality](#)<sup>p731</sup> attribute to guide the choice of filtering algorithm. When such a filtering algorithm requires a pixel value from outside the original image data, it must instead use the value from wrapping the pixel's coordinates to the original image's dimensions. (That is, the filter uses 'repeat' behavior, regardless of the value of the pattern's repetition behavior.)

3. Transform the resulting bitmap according to the pattern's transformation matrix.
4. Transform the resulting bitmap again, this time according to the [current transformation matrix](#)<sup>p709</sup>.
5. Replace any part of the image outside the area in which the pattern is to be rendered with [transparent black](#).
6. The resulting bitmap is what is to be rendered, with the same origin and same scale.

If a radial gradient or repeated pattern is used when the transformation matrix is singular, then the resulting style must be [transparent black](#) (otherwise the gradient or pattern would be collapsed to a point or line, leaving the other pixels undefined). Linear gradients and solid colors always define all points even with singular transformation matrices.

#### 4.12.5.1.10 Drawing rectangles to the bitmap <sup>p71</sup><sub>6</sub>

Objects that implement the [CanvasRect](#)<sup>p683</sup> interface provide the following methods for immediately drawing rectangles to the bitmap. The methods each take four arguments; the first two give the *x* and *y* coordinates of the top left of the rectangle, and the second two give the width *w* and height *h* of the rectangle, respectively.

The [current transformation matrix](#)<sup>p709</sup> must be applied to the following four coordinates, which form the path that must then be closed to get the specified rectangle: (*x*, *y*), (*x*+*w*, *y*), (*x*+*w*, *y*+*h*), (*x*, *y*+*h*).

Shapes are painted without affecting the [current default path](#)<sup>p719</sup>, and are subject to the [clipping region](#)<sup>p720</sup>, and, with the exception of [clearRect\(\)](#)<sup>p716</sup>, also [shadow effects](#)<sup>p732</sup>, [global alpha](#)<sup>p731</sup>, and the [current compositing and blending operator](#)<sup>p731</sup>.

For web developers (non-normative)

**[context.clearRect](#)**<sup>p716</sup>(*x*, *y*, *w*, *h*)

Clears all pixels on the bitmap in the given rectangle to [transparent black](#).

**[context.fillRect](#)**<sup>p717</sup>(*x*, *y*, *w*, *h*)

Paints the given rectangle onto the bitmap, using the current fill style.

**[context.strokeRect](#)**<sup>p717</sup>(*x*, *y*, *w*, *h*)

Paints the box that outlines the given rectangle onto the bitmap, using the current stroke style.

The **[clearRect\(x, y, w, h\)](#)** method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. Let *pixels* be the set of pixels in the specified rectangle that also intersect the current [clipping region](#)<sup>p720</sup>.
3. Clear the pixels in *pixels* to a [transparent black](#), erasing any previous image.

## Note

If either height or width are zero, this method has no effect, since the set of pixels would be empty.

The **fillRect(x, y, w, h)** method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. If either *w* or *h* are zero, then return.
3. Paint the specified rectangular area using [this's fill style](#)<sup>p712</sup>.

The **strokeRect(x, y, w, h)** method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. Take the result of [tracing the path](#)<sup>p692</sup> described below, using the [CanvasPathDrawingStyles](#)<sup>p685</sup> interface's line styles, and fill it with [this's stroke style](#)<sup>p712</sup>.

If both *w* and *h* are zero, the path has a single subpath with just one point (*x*, *y*), and no lines, and this method thus has no effect (the [trace a path](#)<sup>p692</sup> algorithm returns an empty path in that case).

If just one of either *w* or *h* is zero, then the path has a single subpath consisting of two points, with coordinates (*x*, *y*) and (*x*+*w*, *y*+*h*), in that order, connected by a single straight line.

Otherwise, the path has a single subpath consisting of four points, with coordinates (*x*, *y*), (*x*+*w*, *y*), (*x*+*w*, *y*+*h*), and (*x*, *y*+*h*), connected to each other in that order by straight lines.

### 4.12.5.1.11 Drawing text to the bitmap <sup>§<sup>p71</sup></sup><sub>7</sub>

For web developers (non-normative)

**context.fillText**<sup>p717</sup>(*text*, *x*, *y* [, *maxWidth* ])

**context.strokeText**<sup>p717</sup>(*text*, *x*, *y* [, *maxWidth* ])

Fills or strokes (respectively) the given text at the given position. If a maximum width is provided, the text will be scaled to fit that width if necessary.

**metrics = context.measureText**<sup>p718</sup>(*text*)

Returns a [TextMetrics](#)<sup>p686</sup> object with the metrics of the given text in the current font.

**metrics.width**<sup>p718</sup>

**metrics.actualBoundingBoxLeft**<sup>p718</sup>

**metrics.actualBoundingBoxRight**<sup>p718</sup>

**metrics.fontBoundingBoxAscent**<sup>p718</sup>

**metrics.fontBoundingBoxDescent**<sup>p718</sup>

**metrics.actualBoundingBoxAscent**<sup>p718</sup>

**metrics.actualBoundingBoxDescent**<sup>p718</sup>

**metrics.emHeightAscent**<sup>p719</sup>

**metrics.emHeightDescent**<sup>p719</sup>

**metrics.hangingBaseline**<sup>p719</sup>

**metrics.alphabeticBaseline**<sup>p719</sup>

**metrics.ideographicBaseline**<sup>p719</sup>

Returns the measurement described below.

Objects that implement the [CanvasText](#)<sup>p684</sup> interface provide the following methods for rendering text.

The **fillText(text, x, y, maxWidth)** and **strokeText(text, x, y, maxWidth)** methods render the given *text* at the given (*x*, *y*) coordinates ensuring that the text isn't wider than *maxWidth* if specified, using the current [font](#)<sup>p696</sup>, [textAlign](#)<sup>p697</sup>, and [textBaseline](#)<sup>p697</sup> values. Specifically, when the methods are invoked, the user agent must run these steps:

1. If any of the arguments are infinite or NaN, then return.

2. Run the [text preparation algorithm](#)<sup>p700</sup>, passing it text, the object implementing the [CanvasText](#)<sup>p684</sup> interface, and, if the *maxWidth* argument was provided, that argument. Let *glyphs* be the result.
3. Move all the shapes in *glyphs* to the right by *x CSS pixels* and down by *y CSS pixels*.
4. Paint the shapes given in *glyphs*, as transformed by the [current transformation matrix](#)<sup>p709</sup>, with each *CSS pixel* in the coordinate space of *glyphs* mapped to one coordinate space unit.

For [fillText\(\)](#)<sup>p717</sup>, this's [fill style](#)<sup>p712</sup> must be applied to the shapes and this's [stroke style](#)<sup>p712</sup> must be ignored. For [strokeText\(\)](#)<sup>p717</sup>, the reverse holds: this's [stroke style](#)<sup>p712</sup> must be applied to the result of [tracing](#)<sup>p692</sup> the shapes using the object implementing the [CanvasText](#)<sup>p684</sup> interface for the line styles, and this's [fill style](#)<sup>p712</sup> must be ignored.

These shapes are painted without affecting the current path, and are subject to [shadow effects](#)<sup>p732</sup>, [global alpha](#)<sup>p731</sup>, the [clipping region](#)<sup>p720</sup>, and the [current compositing and blending operator](#)<sup>p731</sup>.

The [measureText\(text\)](#) method steps are to run the [text preparation algorithm](#)<sup>p700</sup>, passing it text and the object implementing the [CanvasText](#)<sup>p684</sup> interface, and then using the returned [inline box](#) must return a new [TextMetrics](#)<sup>p686</sup> object with members behaving as described in the following list: [\[CSS\]](#)<sup>p1476</sup>

#### **width attribute**

The width of that [inline box](#), in *CSS pixels*. (The text's advance width.)

#### **actualBoundingBoxLeft attribute**

The distance parallel to the baseline from the alignment point given by the [textAlign](#)<sup>p697</sup> attribute to the left side of the bounding rectangle of the given text, in *CSS pixels*; positive numbers indicating a distance going left from the given alignment point.

#### **Note**

*The sum of this value and the next ([actualBoundingBoxRight](#)<sup>p718</sup>) can be wider than the width of the [inline box](#) ([width](#)<sup>p718</sup>), in particular with slanted fonts where characters overhang their advance width.*

#### **actualBoundingBoxRight attribute**

The distance parallel to the baseline from the alignment point given by the [textAlign](#)<sup>p697</sup> attribute to the right side of the bounding rectangle of the given text, in *CSS pixels*; positive numbers indicating a distance going right from the given alignment point.

#### **fontBoundingBoxAscent attribute**

The distance from the horizontal line indicated by the [textBaseline](#)<sup>p697</sup> attribute to the [ascent metric](#) of the [first available font](#), in *CSS pixels*; positive numbers indicating a distance going up from the given baseline.

#### **Note**

*This value and the next are useful when rendering a background that have to have a consistent height even if the exact text being rendered changes. The [actualBoundingBoxAscent](#)<sup>p718</sup> attribute (and its corresponding attribute for the descent) are useful when drawing a bounding box around specific text.*

#### **fontBoundingBoxDescent attribute**

The distance from the horizontal line indicated by the [textBaseline](#)<sup>p697</sup> attribute to the [descent metric](#) of the [first available font](#), in *CSS pixels*; positive numbers indicating a distance going down from the given baseline.

#### **actualBoundingBoxAscent attribute**

The distance from the horizontal line indicated by the [textBaseline](#)<sup>p697</sup> attribute to the top of the bounding rectangle of the given text, in *CSS pixels*; positive numbers indicating a distance going up from the given baseline.

#### **Note**

*This number can vary greatly based on the input text, even if the first font specified covers all the characters in the input. For example, the [actualBoundingBoxAscent](#)<sup>p718</sup> of a lowercase "o" from an [alphabetic baseline](#) would be less than that of an uppercase "F". The value can easily be negative; for example, the distance from the top of the em box ([textBaseline](#)<sup>p697</sup> value "[top](#)<sup>p698</sup>") to the top of the bounding rectangle when the given text is just a single comma ", " would likely (unless the font is quite unusual) be negative.*

#### **actualBoundingBoxDescent attribute**

The distance from the horizontal line indicated by the [textBaseline](#)<sup>p697</sup> attribute to the bottom of the bounding rectangle of the given text, in *CSS pixels*; positive numbers indicating a distance going down from the given baseline.

### emHeightAscent attribute

The distance from the horizontal line indicated by the `textBaseline`<sup>p697</sup> attribute to the `em-over baseline` in the `inline box`, in `CSS pixels`; positive numbers indicating that the given baseline is below the `em-over baseline` (so this value will usually be positive). Zero if the given baseline is the `em-over baseline`; half the font size if the given baseline is halfway between the `em-over baseline` and the `em-under baseline`.

### emHeightDescent attribute

The distance from the horizontal line indicated by the `textBaseline`<sup>p697</sup> attribute to the `em-under baseline` in the `inline box`, in `CSS pixels`; positive numbers indicating that the given baseline is above the `em-under baseline`. (Zero if the given baseline is the `em-under baseline`.)

### hangingBaseline attribute

The distance from the horizontal line indicated by the `textBaseline`<sup>p697</sup> attribute to the `hanging baseline` of the `inline box`, in `CSS pixels`; positive numbers indicating that the given baseline is below the `hanging baseline`. (Zero if the given baseline is the `hanging baseline`.)

### alphabeticBaseline attribute

The distance from the horizontal line indicated by the `textBaseline`<sup>p697</sup> attribute to the `alphabetic baseline` of the `inline box`, in `CSS pixels`; positive numbers indicating that the given baseline is below the `alphabetic baseline`. (Zero if the given baseline is the `alphabetic baseline`.)

### ideographicBaseline attribute

The distance from the horizontal line indicated by the `textBaseline`<sup>p697</sup> attribute to the `ideographic-under baseline` of the `inline box`, in `CSS pixels`; positive numbers indicating that the given baseline is below the `ideographic-under baseline`. (Zero if the given baseline is the `ideographic-under baseline`.)

#### Note

*Glyphs rendered using `fillText()`<sup>p717</sup> and `strokeText()`<sup>p717</sup> can spill out of the box given by the font size and the width returned by `measureText()`<sup>p718</sup> (the text width). Authors are encouraged to use the bounding box values described above if this is an issue.*

#### Note

*A future version of the 2D context API might provide a way to render fragments of documents, rendered using CSS, straight to the canvas. This would be provided in preference to a dedicated way of doing multiline layout.*

### 4.12.5.1.12 Drawing paths to the canvas <sup>p719</sup>

Objects that implement the `CanvasDrawPath`<sup>p683</sup> interface have a **current default path**. There is only one `current default path`<sup>p719</sup>, it is not part of the `drawing state`<sup>p690</sup>. The `current default path`<sup>p719</sup> is a `path`<sup>p702</sup>, as described above.

#### For web developers (non-normative)

##### `context.beginPath`<sup>p720</sup>()

Resets the `current default path`<sup>p719</sup>.

##### `context.fill`<sup>p720</sup>([ `fillRule` ])

##### `context.fill`<sup>p720</sup>(`path` [, `fillRule` ])

Fills the subpaths of the `current default path`<sup>p719</sup> or the given path with the current fill style, obeying the given fill rule.

##### `context.stroke`<sup>p720</sup>()

##### `context.stroke`<sup>p720</sup>(`path`)

Strokes the subpaths of the `current default path`<sup>p719</sup> or the given path with the current stroke style.

##### `context.clip`<sup>p720</sup>([ `fillRule` ])

##### `context.clip`<sup>p720</sup>(`path` [, `fillRule` ])

Further constrains the clipping region to the `current default path`<sup>p719</sup> or the given path, using the given fill rule to determine what points are in the path.

```
context.isPointInPathp721(x, y [, fillRule ])
```

```
context.isPointInPathp721(path, x, y [, fillRule ])
```

Returns true if the given point is in the [current default path](#)<sup>p719</sup> or the given path, using the given fill rule to determine what points are in the path.

```
context.isPointInStrokep721(x, y)
```

```
context.isPointInStrokep721(path, x, y)
```

Returns true if the given point would be in the region covered by the stroke of the [current default path](#)<sup>p719</sup> or the given path, given the current stroke style.

The **beginPath()** method steps are to empty the list of subpaths in [this's current default path](#)<sup>p719</sup> so that it once again has zero subpaths.

Where the following method definitions use the term **intended path** for a [Path2D](#)<sup>p686</sup>-or-null *path*, it means *path* itself if it is a [Path2D](#)<sup>p686</sup> object, or the [current default path](#)<sup>p719</sup> otherwise.

When the [intended path](#)<sup>p720</sup> is a [Path2D](#)<sup>p686</sup> object, the coordinates and lines of its subpaths must be transformed according to the [current transformation matrix](#)<sup>p709</sup> on the object implementing the [CanvasTransform](#)<sup>p682</sup> interface when used by these methods (without affecting the [Path2D](#)<sup>p686</sup> object itself). When the intended path is the [current default path](#)<sup>p719</sup>, it is not affected by the transform. (This is because transformations already affect the [current default path](#)<sup>p719</sup> when it is constructed, so applying it when it is painted as well would result in a double transformation.)

The **fill(fillRule)** method steps are to run the [fill steps](#)<sup>p720</sup> given [this](#), null, and *fillRule*.

The **fill(path, fillRule)** method steps are to run the [fill steps](#)<sup>p720</sup> given [this](#), *path*, and *fillRule*.

The **fill steps**, given a [CanvasDrawPath](#)<sup>p683</sup> *context*, a [Path2D](#)<sup>p686</sup>-or-null *path*, and a [fill rule](#)<sup>p689</sup> *fillRule*, are to fill all the subpaths of the [intended path](#)<sup>p720</sup> for *path*, using *context*'s [fill style](#)<sup>p712</sup>, and using the [fill rule](#)<sup>p689</sup> indicated by *fillRule*. Open subpaths must be implicitly closed when being filled (without affecting the actual subpaths).

The **stroke()** method steps are to run the [stroke steps](#)<sup>p720</sup> given [this](#) and null.

The **stroke(path)** method steps are to run the [stroke steps](#)<sup>p720</sup> given [this](#) and *path*.

The **stroke steps**, given a [CanvasDrawPath](#)<sup>p683</sup> *context* and a [Path2D](#)<sup>p686</sup>-or-null *path*, are to [trace](#)<sup>p692</sup> the [intended path](#)<sup>p720</sup> for *path*, using *context*'s line styles as set by its [CanvasPathDrawingStyles](#)<sup>p685</sup> mixin, and then fill the resulting path using *context*'s [stroke style](#)<sup>p712</sup>, using the [nonzero winding rule](#)<sup>p689</sup>.

#### Note

*As a result of how the algorithm to [trace a path](#)<sup>p692</sup> is defined, overlapping parts of the paths in one stroke operation are treated as if their union was what was painted.*

#### Note

*The stroke style is affected by the transformation during painting, even if the [current default path](#)<sup>p719</sup> is used.*

Paths, when filled or stroked, must be painted without affecting the [current default path](#)<sup>p719</sup> or any [Path2D](#)<sup>p686</sup> objects, and must be subject to [shadow effects](#)<sup>p732</sup>, [global alpha](#)<sup>p731</sup>, the [clipping region](#)<sup>p720</sup>, and the [current compositing and blending operator](#)<sup>p731</sup>. (The effect of transformations is described above and varies based on which path is being used.)

The **clip(fillRule)** method steps are to run the [clip steps](#)<sup>p720</sup> given [this](#), null, and *fillRule*.

The **clip(path, fillRule)** method steps are to run the [clip steps](#)<sup>p720</sup> given [this](#), *path*, and *fillRule*.

The **clip steps**, given a [CanvasDrawPath](#)<sup>p683</sup> *context*, a [Path2D](#)<sup>p686</sup>-or-null *path*, and a [fill rule](#)<sup>p689</sup> *fillRule*, are to create a new **clipping region** by calculating the intersection of *context*'s current clipping region and the area described by the [intended path](#)<sup>p720</sup> for *path*, using the [fill rule](#)<sup>p689</sup> indicated by *fillRule*. Open subpaths must be implicitly closed when computing the clipping region, without affecting the actual subpaths. The new clipping region replaces the current clipping region.

When the context is initialized, its current clipping region must be set to the largest infinite surface (i.e. by default, no clipping occurs).

The **isPointInPath(x, y, fillRule)** method steps are to return the result of the [is point in path steps](#)<sup>p721</sup> given [this](#), null, x, y, and *fillRule*.

The **isPointInPath(path, x, y, fillRule)** method steps are to return the result of the [is point in path steps](#)<sup>p721</sup> given [this](#), *path*, x, y, and *fillRule*.

The **is point in path steps**, given a [CanvasDrawPath](#)<sup>p683</sup> *context*, a [Path2D](#)<sup>p686</sup>-or-null *path*, two numbers x and y, and a [fill rule](#)<sup>p689</sup> *fillRule*, are:

1. If x or y are infinite or NaN, then return false.
2. If the point given by the x and y coordinates, when treated as coordinates in the canvas coordinate space unaffected by the current transformation, is inside the [intended path](#)<sup>p720</sup> for *path* as determined by the [fill rule](#)<sup>p689</sup> indicated by *fillRule*, then return true. Open subpaths must be implicitly closed when computing the area inside the path, without affecting the actual subpaths. Points on the path itself must be considered to be inside the path.
3. Return false.

The **isPointInStroke(x, y)** method steps are to return the result of the [is point in stroke steps](#)<sup>p721</sup> given [this](#), null, x, and y.

The **isPointInStroke(path, x, y)** method steps are to return the result of the [is point in stroke steps](#)<sup>p721</sup> given [this](#), *path*, x, and y.

The **is point in stroke steps**, given a [CanvasDrawPath](#)<sup>p683</sup> *context*, a [Path2D](#)<sup>p686</sup>-or-null *path*, and two numbers x and y, are:

1. If x or y are infinite or NaN, then return false.
2. If the point given by the x and y coordinates, when treated as coordinates in the canvas coordinate space unaffected by the current transformation, is inside the path that results from [tracing](#)<sup>p692</sup> the [intended path](#)<sup>p720</sup> for *path*, using the [nonzero winding rule](#)<sup>p689</sup>, and using *context*'s line styles as set by its [CanvasPathDrawingStyles](#)<sup>p685</sup> mixin, then return true. Points on the resulting path must be considered to be inside the path.
3. Return false.

### Example

This [canvas](#)<sup>p677</sup> element has a couple of checkboxes. The path-related commands are highlighted:

```
<canvas height=400 width=750>
  <label><input type=checkbox id=showA> Show As</label>
  <label><input type=checkbox id=showB> Show Bs</label>
  <!-- ... -->
</canvas>
<script>
  function drawCheckbox(context, element, x, y, paint) {
    context.save();
    context.font = '10px sans-serif';
    context.textAlign = 'left';
    context.textBaseline = 'middle';
    var metrics = context.measureText(element.labels[0].textContent);
    if (paint) {
      context.beginPath();
      context.strokeStyle = 'black';
      context.rect(x-5, y-5, 10, 10);
      context.stroke();
      if (element.checked) {
        context.fillStyle = 'black';
        context.fill();
      }
      context.fillText(element.labels[0].textContent, x+5, y);
    }
    context.beginPath();
    context.rect(x-7, y-7, 12 + metrics.width+2, 14);
```

```

    context.drawFocusIfNeeded(element);
    context.restore();
}
function drawBase() { /* ... */ }
function drawAs() { /* ... */ }
function drawBs() { /* ... */ }
function redraw() {
    var canvas = document.getElementsByTagName('canvas')[0];
    var context = canvas.getContext('2d');
    context.clearRect(0, 0, canvas.width, canvas.height);
    drawCheckbox(context, document.getElementById('showA'), 20, 40, true);
    drawCheckbox(context, document.getElementById('showB'), 20, 60, true);
    drawBase();
    if (document.getElementById('showA').checked)
        drawAs();
    if (document.getElementById('showB').checked)
        drawBs();
}
function processClick(event) {
    var canvas = document.getElementsByTagName('canvas')[0];
    var context = canvas.getContext('2d');
    var x = event.clientX;
    var y = event.clientY;
    var node = event.target;
    while (node) {
        x -= node.offsetLeft - node.scrollLeft;
        y -= node.offsetTop - node.scrollTop;
        node = node.offsetParent;
    }
    drawCheckbox(context, document.getElementById('showA'), 20, 40, false);
    if (context.isPointInPath(x, y))
        document.getElementById('showA').checked = !(document.getElementById('showA').checked);
    drawCheckbox(context, document.getElementById('showB'), 20, 60, false);
    if (context.isPointInPath(x, y))
        document.getElementById('showB').checked = !(document.getElementById('showB').checked);
    redraw();
}
document.getElementsByTagName('canvas')[0].addEventListener('focus', redraw, true);
document.getElementsByTagName('canvas')[0].addEventListener('blur', redraw, true);
document.getElementsByTagName('canvas')[0].addEventListener('change', redraw, true);
document.getElementsByTagName('canvas')[0].addEventListener('click', processClick, false);
redraw();
</script>

```

#### 4.12.5.1.13 Drawing focus rings <sup>§<sup>p72</sup></sup><sub>2</sub>

For web developers (non-normative)

**context.drawFocusIfNeeded<sup>p722</sup>(element)**

If *element* is [focused<sup>p836</sup>](#), draws a focus ring around the [current default path<sup>p719</sup>](#), following the platform conventions for focus rings.

**context.drawFocusIfNeeded<sup>p723</sup>(path, element)**

If *element* is [focused<sup>p836</sup>](#), draws a focus ring around *path*, following the platform conventions for focus rings.

Objects that implement the [CanvasUserInterface<sup>p684</sup>](#) interface provide the following methods to draw focus rings.

The **drawFocusIfNeeded(*element*)** method steps are to [draw focus if needed<sup>p723</sup>](#) given [this](#), *element*, and [this](#)'s [current default path<sup>p719</sup>](#).

The **drawFocusIfNeeded(path, element)** method steps are to [draw focus if needed](#)<sup>p723</sup> given [this](#), *element*, and *path*.

To **draw focus if needed**, given an object implementing [CanvasUserInterface](#)<sup>p684</sup> *context*, an element *element*, and a [path](#)<sup>p702</sup> *path*:

1. If *element* is not [focused](#)<sup>p836</sup> or is not a descendant of *context*'s [canvas](#)<sup>p677</sup> element, then return.
2. Draw a focus ring of the appropriate style along *path*, following platform conventions.

#### Note

*Some platforms only draw focus rings around elements that have been focused from the keyboard, and not those focused from the mouse. Other platforms simply don't draw focus rings around some elements at all unless relevant accessibility features are enabled. This API is intended to follow these conventions. User agents that implement distinctions based on the manner in which the element was focused are encouraged to classify focus driven by the [focus\(\)](#)<sup>p847</sup> method based on the kind of user interaction event from which the call was triggered (if any).*

The focus ring should not be subject to the [shadow effects](#)<sup>p732</sup>, the [global alpha](#)<sup>p731</sup>, the [current compositing and blending operator](#)<sup>p731</sup>, the [fill style](#)<sup>p712</sup>, the [stroke style](#)<sup>p712</sup>, or any of the members in the [CanvasPathDrawingStyles](#)<sup>p685</sup>, [CanvasTextDrawingStyles](#)<sup>p685</sup> interfaces, but *should* be subject to the [clipping region](#)<sup>p720</sup>. (The effect of transformations is described above and varies based on which path is being used.)

3. [Inform the user](#)<sup>p723</sup> that the focus is at the location given by the intended path. User agents may wait until the next time the [event loop](#)<sup>p1123</sup> reaches its [update the rendering](#)<sup>p1128</sup> step to optionally inform the user.

User agents should not implicitly close open subpaths in the intended path when drawing the focus ring.

#### Note

*This might be a moot point, however. For example, if the focus ring is drawn as an axis-aligned bounding rectangle around the points in the intended path, then whether the subpaths are closed or not has no effect. This specification intentionally does not specify precisely how focus rings are to be drawn: user agents are expected to honor their platform's native conventions.*

"Inform the user", as used in this section, does not imply any persistent state change. It could mean, for instance, calling a system accessibility API to notify assistive technologies such as magnification tools so that the user's magnifier moves to the given area of the canvas. However, it does not associate the path with the element, or provide a region for tactile feedback, etc.

#### 4.12.5.1.14 Drawing images <sup>p72</sup><sub>3</sub>

Objects that implement the [CanvasDrawImage](#)<sup>p684</sup> interface have the **drawImage()** method to draw images.

This method can be invoked with three different sets of arguments:

- `drawImage(image, dx, dy)`
- `drawImage(image, dx, dy, dw, dh)`
- `drawImage(image, sx, sy, sw, sh, dx, dy, dw, dh)`

#### For web developers (non-normative)

**`context.drawImage`**<sup>p723</sup>(*image*, *dx*, *dy*)

**`context.drawImage`**<sup>p723</sup>(*image*, *dx*, *dy*, *dw*, *dh*)

**`context.drawImage`**<sup>p723</sup>(*image*, *sx*, *sy*, *sw*, *sh*, *dx*, *dy*, *dw*, *dh*)

Draws the given image onto the canvas. The arguments are interpreted as follows:

If the image isn't yet fully decoded, then nothing is drawn. If the image is a canvas with no data, throws an ["InvalidStateError" DOMException](#).

When the [drawImage\(\)](#) <sup>p723</sup> method is invoked, the user agent must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. Let *usability* be the result of [checking the usability of image](#) <sup>p711</sup>.
3. If *usability* is *bad*, then return (without drawing anything).
4. Establish the source and destination rectangles as follows:

If not specified, the *dw* and *dh* arguments must default to the values of *sw* and *sh*, interpreted such that one [CSS pixel](#) in the image is treated as one unit in the [output bitmap](#) <sup>p687</sup>'s coordinate space. If the *sx*, *sy*, *sw*, and *sh* arguments are omitted, then they must default to 0, 0, the image's [natural width](#) in image pixels, and the image's [natural height](#) in image pixels, respectively. If the image has no [natural dimensions](#), then the *concrete object size* must be used instead, as determined using the CSS "[Concrete Object Size Resolution](#)" algorithm, with the *specified size* having neither a definite width nor height, nor any additional constraints, the object's natural properties being those of the *image* argument, and the [default object size](#) being the size of the [output bitmap](#) <sup>p687</sup>. [\[CSSIMAGES\]](#) <sup>p1476</sup>

The source rectangle is the rectangle whose corners are the four points (*sx*, *sy*), (*sx*+*sw*, *sy*), (*sx*+*sw*, *sy*+*sh*), (*sx*, *sy*+*sh*).

The destination rectangle is the rectangle whose corners are the four points (*dx*, *dy*), (*dx*+*dw*, *dy*), (*dx*+*dw*, *dy*+*dh*), (*dx*, *dy*+*dh*).

When the source rectangle is outside the source image, the source rectangle must be clipped to the source image and the destination rectangle must be clipped in the same proportion.

#### Note

*When the destination rectangle is outside the destination image (the [output bitmap](#) <sup>p687</sup>), the pixels that land outside the [output bitmap](#) <sup>p687</sup> are discarded, as if the destination was an infinite canvas whose rendering was clipped to the dimensions of the [output bitmap](#) <sup>p687</sup>.*

5. If one of the *sw* or *sh* arguments is zero, then return. Nothing is painted.
6. Paint the region of the *image* argument specified by the source rectangle on the region of the rendering context's [output bitmap](#) <sup>p687</sup> specified by the destination rectangle, after applying the [current transformation matrix](#) <sup>p709</sup> to the destination rectangle.

The image data must be processed in the original direction, even if the dimensions given are negative.

When scaling up, if the [imageSmoothingEnabled](#)<sup>p731</sup> attribute is set to true, the user agent should attempt to apply a smoothing algorithm to the image data when it is scaled. User agents which support multiple filtering algorithms may use the value of the [imageSmoothingQuality](#)<sup>p731</sup> attribute to guide the choice of filtering algorithm when the [imageSmoothingEnabled](#)<sup>p731</sup> attribute is set to true. Otherwise, the image must be rendered using nearest-neighbor interpolation.

**Note**

*This specification does not define the precise algorithm to use when scaling an image down, or when scaling an image up when the [imageSmoothingEnabled](#)<sup>p731</sup> attribute is set to true.*

**Note**

*When a [canvas](#)<sup>p677</sup> element is drawn onto itself, the [drawing model](#)<sup>p734</sup> requires the source to be copied before the image is drawn, so it is possible to copy parts of a [canvas](#)<sup>p677</sup> element onto overlapping parts of itself.*

If the original image data is a bitmap image, then the value painted at a point in the destination rectangle is computed by filtering the original image data. The user agent may use any filtering algorithm (for example bilinear interpolation or nearest-neighbor). When the filtering algorithm requires a pixel value from outside the original image data, it must instead use the value from the nearest edge pixel. (That is, the filter uses 'clamp-to-edge' behavior.) When the filtering algorithm requires a pixel value from outside the source rectangle but inside the original image data, then the value from the original image data must be used.

**Note**

*Thus, scaling an image in parts or in whole will have the same effect. This does mean that when sprites coming from a single sprite sheet are to be scaled, adjacent images in the sprite sheet can interfere. This can be avoided by ensuring each sprite in the sheet is surrounded by a border of [transparent black](#), or by copying sprites to be scaled into temporary [canvas](#)<sup>p677</sup> elements and drawing the scaled sprites from there.*

Images are painted without affecting the current path, and are subject to [shadow effects](#)<sup>p732</sup>, [global alpha](#)<sup>p731</sup>, the [clipping region](#)<sup>p720</sup>, and the [current compositing and blending operator](#)<sup>p731</sup>.

7. If image is [not origin-clean](#)<sup>p712</sup>, then set the [CanvasRenderingContext2D](#)<sup>p682</sup>'s [origin-clean](#)<sup>p678</sup> flag to false.

#### 4.12.5.1.15 Pixel manipulation <sup>p72</sup><sub>5</sub>

**For web developers (non-normative)**

**`imagedata = new ImageDatap726(sw, sh [, settings])`**

Returns an [ImageData](#)<sup>p686</sup> object with the given dimensions and the color space indicated by *settings*. All the pixels in the returned object are [transparent black](#).

Throws an ["IndexSizeError"](#) [DOMException](#) if either of the width or height arguments are zero.

**`imagedata = new ImageDatap726(data, sw [, sh [, settings] ])`**

Returns an [ImageData](#)<sup>p686</sup> object using the data provided in the [Uint8ClampedArray](#) argument, interpreted using the given dimensions and the color space indicated by *settings*.

As each pixel in the data is represented by four numbers, the length of the data needs to be a multiple of four times the given width. If the height is provided as well, then the length needs to be exactly the width times the height times 4.

Throws an ["IndexSizeError"](#) [DOMException](#) if the given data and dimensions can't be interpreted consistently, or if either dimension is zero.

**`imagedata = context.createImageDatap727(imagedata)`**

Returns an [ImageData](#)<sup>p686</sup> object with the same dimensions and color space as the argument. All the pixels in the returned object are [transparent black](#).

**`imagedata = context.createImageDatap726(sw, sh [, settings])`**

Returns an [ImageData](#)<sup>p686</sup> object with the given dimensions. The color space of the returned object is the [color space](#)<sup>p688</sup> of *context* unless overridden by *settings*. All the pixels in the returned object are [transparent black](#).

Throws an ["IndexSizeError"](#) [DOMException](#) if either of the width or height arguments are zero.

**`imagedata = context.getImageDatap727(sx, sy, sw, sh [, settings])`**

Returns an [ImageData<sup>p686</sup>](#) object containing the image data for the given rectangle of the bitmap. The color space of the returned object is the [color space<sup>p688</sup>](#) of *context* unless overridden by *settings*.

Throws an ["IndexSizeError"](#) [DOMException](#) if the either of the width or height arguments are zero.

**`imagedata.widthp727`**

**`imagedata.heightp727`**

Returns the actual dimensions of the data in the [ImageData<sup>p686</sup>](#) object, in pixels.

**`imagedata.datap727`**

Returns the one-dimensional array containing the data in RGBA order, as integers in the range 0 to 255.

**`imagedata.colorSpacep727`**

Returns the color space of the pixels.

**`context.putImageDatap728(imagedata, dx, dy [, dirtyX, dirtyY, dirtyWidth, dirtyHeight ])`**

Paints the data from the given [ImageData<sup>p686</sup>](#) object onto the bitmap. If a dirty rectangle is provided, only the pixels from that rectangle are painted.

The [globalAlpha<sup>p731</sup>](#) and [globalCompositeOperation<sup>p731</sup>](#) properties, as well as the [shadow attributes<sup>p732</sup>](#), are ignored for the purposes of this method call; pixels in the canvas are replaced wholesale, with no composition, alpha blending, no shadows, etc.

Throws an ["InvalidStateError"](#) [DOMException](#) if the *imagedata* object's [data<sup>p727</sup>](#) attribute value's [\[\[ViewedArrayBuffer\]\]](#) internal slot is detached.

Objects that implement the [CanvasImageData<sup>p684</sup>](#) interface provide the following methods for reading and writing pixel data to the bitmap.

The **`new ImageData(sw, sh, settings)`** constructor steps are:

1. If one or both of *sw* and *sh* are zero, then throw an ["IndexSizeError"](#) [DOMException](#).
2. [Initialize<sup>p727</sup>](#) *this* given *sw*, *sh*, and [settings<sup>p727</sup>](#) set to *settings*.
3. Initialize the image data of *this* to [transparent black](#).

The **`new ImageData(data, sw, sh, settings)`** constructor steps are:

1. Let *length* be the number of bytes in *data*.
2. If *length* is not a nonzero integral multiple of four, then throw an ["InvalidStateError"](#) [DOMException](#).
3. Let *length* be *length* divided by four.
4. If *length* is not an integral multiple of *sw*, then throw an ["IndexSizeError"](#) [DOMException](#).

**Note**

*At this step, the length is guaranteed to be greater than zero (otherwise the second step above would have aborted the steps), so if *sw* is zero, this step will throw the exception and return.*

5. Let *height* be *length* divided by *sw*.
6. If *sh* was given and its value is not equal to *height*, then throw an ["IndexSizeError"](#) [DOMException](#).
7. [Initialize<sup>p727</sup>](#) *this* given *sw*, *sh*, [settings<sup>p727</sup>](#) set to *settings*, and [source<sup>p727</sup>](#) set to *data*.

**Note**

*This step does not set *this*'s data to a copy of *data*. It sets it to the actual [Uint8ClampedArray](#) object passed as *data*.*

The **`createImageData(sw, sh, settings)`** method steps are:

1. If one or both of *sw* and *sh* are zero, then throw an ["IndexSizeError"](#) [DOMException](#).
2. Let *newImageData* be a [new ImageData<sup>p686</sup>](#) object.
3. [Initialize<sup>p727</sup>](#) *newImageData* given the absolute magnitude of *sw*, the absolute magnitude of *sh*, [settings<sup>p727</sup>](#) set to *settings*,

and [defaultColorSpace<sup>p727</sup>](#) set to [this's color space<sup>p688</sup>](#).

4. Initialize the image data of *newImageData* to [transparent black](#).
5. Return *newImageData*.

The **`createImageData(imagedata)`** method steps are:

1. Let *newImageData* be a [new ImageData<sup>p686</sup>](#) object.
2. [Initialize<sup>p727</sup>](#) *newImageData* given the value of *imagedata*'s [width<sup>p727</sup>](#) attribute, the value of *imagedata*'s [height<sup>p727</sup>](#) attribute, and [defaultColorSpace<sup>p727</sup>](#) set to the value of *imagedata*'s [colorSpace<sup>p727</sup>](#) attribute.
3. Initialize the image data of *newImageData* to [transparent black](#).
4. Return *newImageData*.

The **`getImageData(sx, sy, sw, sh, settings)`** method steps are:

1. If either the *sw* or *sh* arguments are zero, then throw an ["IndexSizeError" DOMException](#).
2. If the [CanvasRenderingContext2D<sup>p682</sup>](#)'s [origin-clean<sup>p678</sup>](#) flag is set to false, then throw a ["SecurityError" DOMException](#).
3. Let *imageData* be a [new ImageData<sup>p686</sup>](#) object.
4. [Initialize<sup>p727</sup>](#) *imageData* given *sw*, *sh*, [settings<sup>p727</sup>](#) set to *settings*, and [defaultColorSpace<sup>p727</sup>](#) set to [this's color space<sup>p688</sup>](#).
5. Let the source rectangle be the rectangle whose corners are the four points (*sx*, *sy*), (*sx*+*sw*, *sy*), (*sx*+*sw*, *sy*+*sh*), (*sx*, *sy*+*sh*).
6. Set the pixel values of *imageData* to be the pixels of [this's output bitmap<sup>p687</sup>](#) in the area specified by the source rectangle in the bitmap's coordinate space units, converted from [this's color space<sup>p688</sup>](#) to *imageData*'s [colorSpace<sup>p727</sup>](#) using ['relative-colorimetric'](#) rendering intent.
7. Set the pixels values of *imageData* for areas of the source rectangle that are outside of the [output bitmap<sup>p687</sup>](#) to [transparent black](#).
8. Return *imageData*.

To **initialize an ImageData object** *imageData*, given a positive integer number of rows *rows*, a positive integer number of pixels per row *pixelsPerRow*, an optional [ImageDataSettings<sup>p686</sup>](#) ***settings***, an optional [Uint8ClampedArray](#) ***source***, and an optional [PredefinedColorSpace<sup>p682</sup>](#) ***defaultColorSpace***:

MDN

1. If *source* was given, then initialize the ***data*** attribute of *imageData* to *source*.
2. Otherwise (*source* was not given), initialize the ***data*<sup>p727</sup>** attribute of *imageData* to a new [Uint8ClampedArray](#) object. The [Uint8ClampedArray](#) object must use a new [Canvas Pixel ArrayBuffer<sup>p728</sup>](#) for its storage, and must have a zero start offset and a length equal to the length of its storage, in bytes. The [Canvas Pixel ArrayBuffer<sup>p728</sup>](#) must have the correct size to store *rows* × *pixelsPerRow* pixels.

If the [Canvas Pixel ArrayBuffer<sup>p728</sup>](#) cannot be allocated, then rethrow the [RangeError](#) thrown by JavaScript, and return.

3. Initialize the ***width*** attribute of *imageData* to *pixelsPerRow*.
4. Initialize the ***height*** attribute of *imageData* to *rows*.
5. If *settings* was given and *settings*[["colorSpace<sup>p727</sup>"](#)] [exists](#), then initialize the ***colorSpace*** attribute of *imageData* to *settings*[["colorSpace"](#)].
6. Otherwise, if *defaultColorSpace* was given, then initialize the ***colorSpace<sup>p727</sup>*** attribute of *imageData* to *defaultColorSpace*.
7. Otherwise, initialize the ***colorSpace<sup>p727</sup>*** attribute of *imageData* to ["srgb<sup>p689</sup>"](#).

[ImageData<sup>p686</sup>](#) objects are [serializable objects<sup>p117</sup>](#). Their [serialization steps<sup>p117</sup>](#), given *value* and *serialized*, are:

1. Set *serialized*[[Data]] to the [sub-serialization<sup>p122</sup>](#) of the value of *value*'s ***data<sup>p727</sup>*** attribute.
2. Set *serialized*[[Width]] to the value of *value*'s ***width<sup>p727</sup>*** attribute.

3. Set `serialized.[[Height]]` to the value of `value`'s `height`<sup>p727</sup> attribute.
4. Set `serialized.[[ColorSpace]]` to the value of `value`'s `colorSpace`<sup>p727</sup> attribute.

Their `deserialization_steps`<sup>p117</sup>, given `serialized`, `value`, and `targetRealm`, are:

1. Initialize `value`'s `data`<sup>p727</sup> attribute to the `sub-deserialization`<sup>p125</sup> of `serialized.[[Data]]`.
2. Initialize `value`'s `width`<sup>p727</sup> attribute to `serialized.[[Width]]`.
3. Initialize `value`'s `height`<sup>p727</sup> attribute to `serialized.[[Height]]`.
4. Initialize `value`'s `colorSpace`<sup>p727</sup> attribute to `serialized.[[ColorSpace]]`.

A **Canvas Pixel ArrayBuffer** is an `ArrayBuffer` whose data is represented in left-to-right order, row by row top to bottom, starting with the top left, with each pixel's red, green, blue, and alpha components being given in that order for each pixel. Each component of each pixel represented in this array must be in the range 0..255, representing the 8 bit value for that component. The components must be assigned consecutive indices starting with 0 for the top left pixel's red component.

The `putImageData()` method writes data from `ImageData`<sup>p686</sup> structures back to the rendering context's `output bitmap`<sup>p687</sup>. Its arguments are: `imagedata`, `dx`, `dy`, `dirtyX`, `dirtyY`, `dirtyWidth`, and `dirtyHeight`.

When the last four arguments to this method are omitted, they must be assumed to have the values 0, 0, the `width`<sup>p727</sup> member of the `imagedata` structure, and the `height`<sup>p727</sup> member of the `imagedata` structure, respectively.

The method, when invoked, must act as follows:

1. Let `buffer` be `imagedata`'s `data`<sup>p727</sup> attribute value's `[[ViewedArrayBuffer]]` internal slot.
2. If `IsDetachedBuffer(buffer)` is true, then throw an `"InvalidStateError"` `DOMException`.
3. If `dirtyWidth` is negative, then let `dirtyX` be `dirtyX+dirtyWidth`, and let `dirtyWidth` be equal to the absolute magnitude of `dirtyWidth`.  
  
If `dirtyHeight` is negative, then let `dirtyY` be `dirtyY+dirtyHeight`, and let `dirtyHeight` be equal to the absolute magnitude of `dirtyHeight`.
4. If `dirtyX` is negative, then let `dirtyWidth` be `dirtyWidth+dirtyX`, and let `dirtyX` be zero.  
  
If `dirtyY` is negative, then let `dirtyHeight` be `dirtyHeight+dirtyY`, and let `dirtyY` be zero.
5. If `dirtyX+dirtyWidth` is greater than the `width`<sup>p727</sup> attribute of the `imagedata` argument, then let `dirtyWidth` be the value of that `width`<sup>p727</sup> attribute, minus the value of `dirtyX`.  
  
If `dirtyY+dirtyHeight` is greater than the `height`<sup>p727</sup> attribute of the `imagedata` argument, then let `dirtyHeight` be the value of that `height`<sup>p727</sup> attribute, minus the value of `dirtyY`.
6. If, after those changes, either `dirtyWidth` or `dirtyHeight` are negative or zero, then return without affecting any bitmaps.
7. For all integer values of `x` and `y` where `dirtyX ≤ x < dirtyX+dirtyWidth` and `dirtyY ≤ y < dirtyY+dirtyHeight`, copy the four channels of the pixel with coordinate `(x, y)` in the `imagedata` data structure's `Canvas Pixel ArrayBuffer`<sup>p728</sup> to the pixel with coordinate `(dx+x, dy+y)` in the rendering context's `output bitmap`<sup>p687</sup>.

#### Note

Due to the lossy nature of converting between color spaces and converting to and from `premultiplied alpha`<sup>p748</sup> color values, pixels that have just been set using `putImageData()`<sup>p728</sup>, and are not completely opaque, might be returned to an equivalent `getImageData()`<sup>p727</sup> as different values.

The current path, `transformation matrix`<sup>p709</sup>, `shadow attributes`<sup>p732</sup>, `global alpha`<sup>p731</sup>, the `clipping region`<sup>p720</sup>, and `current compositing and blending operator`<sup>p731</sup> must not affect the methods described in this section.

#### Example

In the following example, the script generates an `ImageData`<sup>p686</sup> object so that it can draw onto it.

```
// canvas is a reference to a <canvas> element
```

```

var context = canvas.getContext('2d');

// create a blank slate
var data = context.createImageData(canvas.width, canvas.height);

// create some plasma
FillPlasma(data, 'green'); // green plasma

// add a cloud to the plasma
AddCloud(data, data.width/2, data.height/2); // put a cloud in the middle

// paint the plasma+cloud on the canvas
context.putImageData(data, 0, 0);

// support methods
function FillPlasma(data, color) { ... }
function AddCloud(data, x, y) { ... }

```

### Example

Here is an example of using [getImageData\(\)](#)<sup>p727</sup> and [putImageData\(\)](#)<sup>p728</sup> to implement an edge detection filter.

```

<!DOCTYPE HTML>
<html lang="en">
<head>
<title>Edge detection demo</title>
<script>
var image = new Image();
function init() {
    image.onload = demo;
    image.src = "image.jpeg";
}
function demo() {
    var canvas = document.getElementsByTagName('canvas')[0];
    var context = canvas.getContext('2d');

    // draw the image onto the canvas
    context.drawImage(image, 0, 0);

    // get the image data to manipulate
    var input = context.getImageData(0, 0, canvas.width, canvas.height);

    // get an empty slate to put the data into
    var output = context.createImageData(canvas.width, canvas.height);

    // alias some variables for convenience
    // In this case input.width and input.height
    // match canvas.width and canvas.height
    // but we'll use the former to keep the code generic.
    var w = input.width, h = input.height;
    var inputData = input.data;
    var outputData = output.data;

    // edge detection
    for (var y = 1; y < h-1; y += 1) {
        for (var x = 1; x < w-1; x += 1) {
            for (var c = 0; c < 3; c += 1) {
                var i = (y*w + x)*4 + c;
                outputData[i] = 127 + -inputData[i - w*4 - 4] -    inputData[i - w*4] - inputData[i -
w*4 + 4] +

```

```

        -inputData[i - 4]      + 8*inputData[i]      - inputData[i + 4]
+
        -inputData[i + w*4 - 4] -   inputData[i + w*4] - inputData[i +
w*4 + 4];
    }
    outputData[(y*w + x)*4 + 3] = 255; // alpha
    }
}

// put the image data back after manipulation
context.putImageData(output, 0, 0);
}
</script>
</head>
<body onload="init()">
<canvas></canvas>
</body>
</html>

```

### Example

Here is an example of color space conversion applied when drawing a solid color and reading the result back using and `getImageData()` <sup>p727</sup>.

```

<!DOCTYPE HTML>
<html lang="en">
<title>Color space image data demo</title>

<canvas></canvas>

<script>
const canvas = document.querySelector('canvas');
const context = canvas.getContext('2d', {colorSpace: 'display-p3'});

// Draw a red rectangle. Note that the hex color notation
// specifies sRGB colors.
context.fillStyle = "#FF0000";
context.fillRect(0, 0, 64, 64);

// Get the image data.
const pixels = context.getImageData(0, 0, 1, 1);

// This will print 'display-p3', reflecting the default behavior
// of returning image data in the canvas's color space.
console.log(pixels.colorSpace);

// This will print the values 234, 51, and 35, reflecting the
// red fill color, converted to 'display-p3'.
console.log(pixels.data[0]);
console.log(pixels.data[1]);
console.log(pixels.data[2]);
</script>

```

#### 4.12.5.1.16 Compositing <sup>§p73</sup><sub>0</sub>

For web developers (non-normative)

**context.globalAlpha**<sup>p731</sup> [ = value ]

Returns the current [global alpha](#)<sup>p731</sup> value applied to rendering operations.

Can be set, to change the [global alpha](#)<sup>p731</sup> value. Values outside of the range 0.0 .. 1.0 are ignored.

**context.globalCompositeOperation**<sup>p731</sup> [ = value ]

Returns the [current compositing and blending operator](#)<sup>p731</sup>, from the values defined in *Compositing and Blending*.  
[\[COMPOSITE\]](#)<sup>p1475</sup>

Can be set, to change the [current compositing and blending operator](#)<sup>p731</sup>. Unknown values are ignored.

Objects that implement the [CanvasCompositing](#)<sup>p683</sup> interface have a [global alpha](#)<sup>p731</sup> value and a [current compositing and blending operator](#)<sup>p731</sup> value that both affect all the drawing operations on this object.

The **global alpha** value gives an alpha value that is applied to shapes and images before they are composited onto the [output bitmap](#)<sup>p687</sup>. The value ranges from 0.0 (fully transparent) to 1.0 (no additional transparency). It must initially have the value 1.0.

The **globalAlpha** getter steps are to return [this's global alpha](#)<sup>p731</sup>.

The **globalAlpha**<sup>p731</sup> setter steps are:

1. If the given value is either infinite, NaN, or not in the range 0.0 to 1.0, then return.
2. Otherwise, set [this's global alpha](#)<sup>p731</sup> to the given value.

The **current compositing and blending operator** value controls how shapes and images are drawn onto the [output bitmap](#)<sup>p687</sup>, once they have had the [global alpha](#)<sup>p731</sup> and the [current transformation matrix](#)<sup>p709</sup> applied. Initially, it must be set to "[source-over](#)".

The **globalCompositeOperation** getter steps are to return [this's current compositing and blending operator](#)<sup>p731</sup>.

The **globalCompositeOperation**<sup>p731</sup> setter steps are:

1. If the given value is not [identical to](#) any of the values that the [<blend-mode>](#) or the [<composite-mode>](#) properties are defined to take, then return. [\[COMPOSITE\]](#)<sup>p1475</sup>
2. Otherwise, set [this's current compositing and blending operator](#)<sup>p731</sup> to the given value.

#### 4.12.5.1.17 Image smoothing <sup>p73</sup><sub>1</sub>

For web developers (non-normative)

**context.imageSmoothingEnabled**<sup>p731</sup> [ = value ]

Returns whether pattern fills and the [drawImage\(\)](#)<sup>p723</sup> method will attempt to smooth images if their pixels don't line up exactly with the display, when scaling images up.

Can be set, to change whether images are smoothed (true) or not (false).

**context.imageSmoothingQuality**<sup>p731</sup> [ = value ]

Returns the current image-smoothing-quality preference.

Can be set, to change the preferred quality of image smoothing. The possible values are "[low](#)<sup>p689</sup>", "[medium](#)<sup>p689</sup>" and "[high](#)<sup>p689</sup>". Unknown values are ignored.

Objects that implement the [CanvasImageSmoothing](#)<sup>p683</sup> interface have attributes that control how image smoothing is performed.

The **imageSmoothingEnabled** attribute, on getting, must return the last value it was set to. On setting, it must be set to the new value. When the object implementing the [CanvasImageSmoothing](#)<sup>p683</sup> interface is created, the attribute must be set to true.

The **imageSmoothingQuality** attribute, on getting, must return the last value it was set to. On setting, it must be set to the new value. When the object implementing the [CanvasImageSmoothing](#)<sup>p683</sup> interface is created, the attribute must be set to "[low](#)<sup>p689</sup>".

#### 4.12.5.1.18 Shadows <sup>p73</sup><sub>2</sub>

All drawing operations on an object which implements the [CanvasShadowStyles](#)<sup>p683</sup> interface are affected by the four global shadow attributes.

For web developers (non-normative)

**context.shadowColor**<sup>p732</sup> [ = value ]

Returns the current shadow color.

Can be set, to change the shadow color. Values that cannot be parsed as CSS colors are ignored.

**context.shadowOffsetX**<sup>p732</sup> [ = value ]

**context.shadowOffsetY**<sup>p732</sup> [ = value ]

Returns the current shadow offset.

Can be set, to change the shadow offset. Values that are not finite numbers are ignored.

**context.shadowBlur**<sup>p732</sup> [ = value ]

Returns the current level of blur applied to shadows.

Can be set, to change the blur level. Values that are not finite numbers greater than or equal to zero are ignored.

Objects which implement the [CanvasShadowStyles](#)<sup>p683</sup> interface have an associated **shadow color**, which is a CSS color. Initially, it must be [transparent black](#).

The **shadowColor** getter steps are to return the [serialization](#) of [this](#)'s [shadow color](#)<sup>p732</sup> with [HTML-compatible serialization requested](#).

The [shadowColor](#)<sup>p732</sup> setter steps are:

1. Let *context* be [this](#)'s [canvas](#)<sup>p689</sup> attribute's value, if that is an element; otherwise null.
2. Let *parsedValue* be the result of [parsing](#) the given value with *context* if non-null.
3. If *parsedValue* is failure, then return.
4. Set [this](#)'s [shadow color](#)<sup>p732</sup> to *parsedValue*.

The **shadowOffsetX** and **shadowOffsetY** attributes specify the distance that the shadow will be offset in the positive horizontal and positive vertical distance respectively. Their values are in coordinate space units. They are not affected by the current transformation matrix.

When the context is created, the shadow offset attributes must initially have the value 0.

On getting, they must return their current value. On setting, the attribute being set must be set to the new value, except if the value is infinite or NaN, in which case the new value must be ignored.

The **shadowBlur** attribute specifies the level of the blurring effect. (The units do not map to coordinate space units, and are not affected by the current transformation matrix.)

When the context is created, the [shadowBlur](#)<sup>p732</sup> attribute must initially have the value 0.

On getting, the attribute must return its current value. On setting, the attribute must be set to the new value, except if the value is negative, infinite or NaN, in which case the new value must be ignored.

**Shadows are only drawn if** the opacity component of the alpha component of the [shadow color](#)<sup>p732</sup> is nonzero and either the [shadowBlur](#)<sup>p732</sup> is nonzero, or the [shadowOffsetX](#)<sup>p732</sup> is nonzero, or the [shadowOffsetY](#)<sup>p732</sup> is nonzero.

[When shadows are drawn](#)<sup>p732</sup>, they must be rendered as follows:

1. Let *A* be an infinite [transparent black](#) bitmap on which the source image for which a shadow is being created has been rendered.
2. Let *B* be an infinite [transparent black](#) bitmap, with a coordinate space and an origin identical to *A*.
3. Copy the alpha channel of *A* to *B*, offset by [shadowOffsetX](#)<sup>p732</sup> in the positive x direction, and [shadowOffsetY](#)<sup>p732</sup> in the positive y direction.
4. If [shadowBlur](#)<sup>p732</sup> is greater than 0:

1. Let  $\sigma$  be half the value of [shadowBlur<sup>p732</sup>](#).
2. Perform a 2D Gaussian Blur on  $B$ , using  $\sigma$  as the standard deviation.

User agents may limit values of  $\sigma$  to an implementation-specific maximum value to avoid exceeding hardware limitations during the Gaussian blur operation.

5. Set the red, green, and blue components of every pixel in  $B$  to the red, green, and blue components (respectively) of the [shadow\\_color<sup>p732</sup>](#).
6. Multiply the alpha component of every pixel in  $B$  by the alpha component of the [shadow\\_color<sup>p732</sup>](#).
7. The shadow is in the bitmap  $B$ , and is rendered as part of the [drawing\\_model<sup>p734</sup>](#) described below.

If the [current\\_compositing\\_and\\_blending\\_operator<sup>p731</sup>](#) is "copy", then shadows effectively won't render (since the shape will overwrite the shadow).

#### 4.12.5.1.19 Filters <sup>p73</sup><sub>3</sub>

All drawing operations on an object which implements the [CanvasFilters<sup>p683</sup>](#) interface are affected by the global **filter** attribute.

For web developers (non-normative)

**context.filter<sup>p733</sup> [ = value ]**

Returns the current filter.

Can be set, to change the filter. Values can either be the string "none" or a string parseable as a [<filter-value-list>](#). Other values are ignored.

Such objects have an associated **current filter**, which is a string. Initially the [current filter<sup>p733</sup>](#) is set to the string "none". Whenever the value of the [current filter<sup>p733</sup>](#) is the string "none" filters will be disabled for the context.

The [filter<sup>p733</sup>](#) getter steps are to return [this's current filter<sup>p733</sup>](#).

The [filter<sup>p733</sup>](#) setter steps are:

1. If the given value is "none", then set [this's current filter<sup>p733</sup>](#) to "none" and return.
2. Let *parsedValue* be the result of [parsing](#) the given values as a [<filter-value-list>](#). If any property-independent style sheet syntax like 'inherit' or 'initial' is present, then this parsing must return failure.
3. If *parsedValue* is failure, then return.
4. Set [this's current filter<sup>p733</sup>](#) to the given value.

#### Note

*Though context.filter<sup>p733</sup> = "none" will disable filters for the context, context.filter<sup>p733</sup> = "", context.filter<sup>p733</sup> = null, and context.filter<sup>p733</sup> = undefined are all treated as unparseable inputs and the value of the [current filter<sup>p733</sup>](#) is left unchanged.*

Coordinates used in the value of the [current filter<sup>p733</sup>](#) are interpreted such that one pixel is equivalent to one SVG user space unit and to one canvas coordinate space unit. Filter coordinates are not affected by the [current transformation matrix<sup>p709</sup>](#). The current transformation matrix affects only the input to the filter. Filters are applied in the [output\\_bitmap<sup>p687</sup>](#)'s coordinate space.

When the value of the [current filter<sup>p733</sup>](#) is a string parseable as a [<filter-value-list>](#) which defines lengths using percentages or using 'em' or 'ex' units, these must be interpreted relative to the [computed value](#) of the 'font-size' property of the [font style source object<sup>p695</sup>](#) at the time that the attribute is set. If the [computed values](#) are undefined for a particular case (e.g. because the [font style source object<sup>p695</sup>](#) is not an element or is not [being rendered<sup>p1388</sup>](#)), then the relative keywords must be interpreted relative to the default value of the [font<sup>p696</sup>](#) attribute. The 'larger' and 'smaller' keywords are not supported.

If the value of the [current filter<sup>p733</sup>](#) is a string parseable as a [<filter-value-list>](#) with a reference to an SVG filter in the same document, and this SVG filter changes, then the changed filter is used for the next draw operation.

If the value of the [current filter<sup>p733</sup>](#) is a string parseable as a [<filter-value-list>](#) with a reference to an SVG filter in an external resource

document and that document is not loaded when a drawing operation is invoked, then the drawing operation must proceed with no filtering.

#### 4.12.5.1.20 Working with externally-defined SVG filters §<sup>p73</sup><sub>4</sub>

*This section is non-normative.*

Since drawing is performed using filter value "none" until an externally-defined filter has finished loading, authors might wish to determine whether such a filter has finished loading before proceeding with a drawing operation. One way to accomplish this is to load the externally-defined filter elsewhere within the same page in some element that sends a `load` event (for example, an [SVG use](#) element), and wait for the `load` event to be dispatched.

#### 4.12.5.1.21 Drawing model §<sup>p73</sup><sub>4</sub>

When a shape or image is painted, user agents must follow these steps, in the order given (or act as if they do):

1. Render the shape or image onto an infinite [transparent black](#) bitmap, creating image *A*, as described in the previous sections. For shapes, the current fill, stroke, and line styles must be honored, and the stroke must itself also be subjected to the current transformation matrix.
2. Multiply the alpha component of every pixel in *A* by [global\\_alpha](#)<sup>p731</sup>.
3. When the [current filter](#)<sup>p733</sup> is set to a value other than "none" and all the externally-defined filters it references, if any, are in documents that are currently loaded, then use image *A* as the input to the [current filter](#)<sup>p733</sup>, creating image *B*. If the [current filter](#)<sup>p733</sup> is a string parseable as a [<filter-value-list>](#), then draw using the [current filter](#)<sup>p733</sup> in the same manner as SVG. Otherwise, let *B* be an alias for *A*.
4. [When shadows are drawn](#)<sup>p732</sup>, render the shadow from image *B*, using the current shadow styles, creating image *C*.
5. [When shadows are drawn](#)<sup>p732</sup>, composite *C* within the [clipping region](#)<sup>p720</sup> over the current [output bitmap](#)<sup>p687</sup> using the [current compositing and blending operator](#)<sup>p731</sup>.
6. Composite *B* within the [clipping region](#)<sup>p720</sup> over the current [output bitmap](#)<sup>p687</sup> using the [current compositing and blending operator](#)<sup>p731</sup>.

When compositing onto the [output bitmap](#)<sup>p687</sup>, pixels that would fall outside of the [output bitmap](#)<sup>p687</sup> must be discarded.

#### 4.12.5.1.22 Best practices §<sup>p73</sup><sub>4</sub>

When a canvas is interactive, authors should include [focusable](#)<sup>p837</sup> elements in the element's fallback content corresponding to each [focusable](#)<sup>p837</sup> part of the canvas, as in the [example above](#)<sup>p721</sup>.

When rendering focus rings, to ensure that focus rings have the appearance of native focus rings, authors should use the [drawFocusIfNeeded\(\)](#)<sup>p722</sup> method, passing it the element for which a ring is being drawn. This method only draws the focus ring if the element is [focused](#)<sup>p836</sup>, so that it can simply be called whenever drawing the element, without checking whether the element is focused or not first.

Authors should avoid implementing text editing controls using the [canvas](#)<sup>p677</sup> element. Doing so has a large number of disadvantages:

- Mouse placement of the caret has to be reimplemented.
- Keyboard movement of the caret has to be reimplemented (possibly across lines, for multiline text input).
- Scrolling of the text control has to be implemented (horizontally for long lines, vertically for multiline input).
- Native features such as copy-and-paste have to be reimplemented.
- Native features such as spell-checking have to be reimplemented.
- Native features such as drag-and-drop have to be reimplemented.

- Native features such as page-wide text search have to be reimplemented.
- Native features specific to the user, for example custom text services, have to be reimplemented. This is close to impossible since each user might have different services installed, and there is an unbounded set of possible such services.
- Bidirectional text editing has to be reimplemented.
- For multiline text editing, line wrapping has to be implemented for all relevant languages.
- Text selection has to be reimplemented.
- Dragging of bidirectional text selections has to be reimplemented.
- Platform-native keyboard shortcuts have to be reimplemented.
- Platform-native input method editors (IMEs) have to be reimplemented.
- Undo and redo functionality has to be reimplemented.
- Accessibility features such as magnification following the caret or selection have to be reimplemented.

This is a huge amount of work, and authors are most strongly encouraged to avoid doing any of it by instead using the [input](#)<sup>p520</sup> element, the [textarea](#)<sup>p579</sup> element, or the [contenteditable](#)<sup>p853</sup> attribute.

#### 4.12.5.1.23 Examples <sup>§p73</sup><sub>5</sub>

*This section is non-normative.*

##### Example

Here is an example of a script that uses canvas to draw [pretty glowing lines](#).

```
<canvas width="800" height="450"></canvas>
<script>

var context = document.getElementsByTagName('canvas')[0].getContext('2d');

var lastX = context.canvas.width * Math.random();
var lastY = context.canvas.height * Math.random();
var hue = 0;
function line() {
  context.save();
  context.translate(context.canvas.width/2, context.canvas.height/2);
  context.scale(0.9, 0.9);
  context.translate(-context.canvas.width/2, -context.canvas.height/2);
  context.beginPath();
  context.lineWidth = 5 + Math.random() * 10;
  context.moveTo(lastX, lastY);
  lastX = context.canvas.width * Math.random();
  lastY = context.canvas.height * Math.random();
  context.bezierCurveTo(context.canvas.width * Math.random(),
                        context.canvas.height * Math.random(),
                        context.canvas.width * Math.random(),
                        context.canvas.height * Math.random(),
                        lastX, lastY);

  hue = hue + 10 * Math.random();
  context.strokeStyle = 'hsl(' + hue + ', 50%, 50%)';
  context.shadowColor = 'white';
  context.shadowBlur = 10;
  context.stroke();
  context.restore();
}
setInterval(line, 50);
```

```
function blank() {
  context.fillStyle = 'rgba(0,0,0,0.1)';
  context.fillRect(0, 0, context.canvas.width, context.canvas.height);
}
setInterval(blank, 40);

</script>
```

## Example

The 2D rendering context for [canvas<sup>p677</sup>](#) is often used for sprite-based games. The following example demonstrates this:

Here is the source for this example:

```
<!DOCTYPE HTML>
<html lang="en">
<meta charset="utf-8">
<title>Blue Robot Demo</title>
<style>
  html { overflow: hidden; min-height: 200px; min-width: 380px; }
  body { height: 200px; position: relative; margin: 8px; }
  .buttons { position: absolute; bottom: 0px; left: 0px; margin: 4px; }
</style>
<canvas width="380" height="200"></canvas>
<script>
var Landscape = function (context, width, height) {
  this.offset = 0;
  this.width = width;
  this.advance = function (dx) {
    this.offset += dx;
  };
  this.horizon = height * 0.7;
  // This creates the sky gradient (from a darker blue to white at the bottom)
  this.sky = context.createLinearGradient(0, 0, 0, this.horizon);
  this.sky.addColorStop(0.0, 'rgb(55,121,179)');
  this.sky.addColorStop(0.7, 'rgb(121,194,245)');
  this.sky.addColorStop(1.0, 'rgb(164,200,214)');
  // this creates the grass gradient (from a darker green to a lighter green)
  this.earth = context.createLinearGradient(0, this.horizon, 0, height);
  this.earth.addColorStop(0.0, 'rgb(81,140,20)');
  this.earth.addColorStop(1.0, 'rgb(123,177,57)');
  this.paintBackground = function (context, width, height) {
    // first, paint the sky and grass rectangles
    context.fillStyle = this.sky;
```

```

context.fillRect(0, 0, width, this.horizon);
context.fillStyle = this.earth;
context.fillRect(0, this.horizon, width, height-this.horizon);
// then, draw the cloudy banner
// we make it cloudy by having the draw text off the top of the
// canvas, and just having the blurred shadow shown on the canvas
context.save();
context.translate(width-((this.offset+(this.width*3.2)) % (this.width*4.0))+0, 0);
context.shadowColor = 'white';
context.shadowOffsetY = 30+this.horizon/3; // offset down on canvas
context.shadowBlur = '5';
context.fillStyle = 'white';
context.textAlign = 'left';
context.textBaseline = 'top';
context.font = '20px sans-serif';
context.fillText('WHATWG ROCKS', 10, -30); // text up above canvas
context.restore();
// then, draw the background tree
context.save();
context.translate(width-((this.offset+(this.width*0.2)) % (this.width*1.5))+30, 0);
context.beginPath();
context.fillStyle = 'rgb(143,89,2)';
context.strokeStyle = 'rgb(10,10,10)';
context.lineWidth = 2;
context.rect(0, this.horizon+5, 10, -50); // trunk
context.fill();
context.stroke();
context.beginPath();
context.fillStyle = 'rgb(78,154,6)';
context.arc(5, this.horizon-60, 30, 0, Math.PI*2); // leaves
context.fill();
context.stroke();
context.restore();
};

this.paintForeground = function (context, width, height) {
  // draw the box that goes in front
  context.save();
  context.translate(width-((this.offset+(this.width*0.7)) % (this.width*1.1))+0, 0);
  context.beginPath();
  context.rect(0, this.horizon - 5, 25, 25);
  context.fillStyle = 'rgb(220,154,94)';
  context.strokeStyle = 'rgb(10,10,10)';
  context.lineWidth = 2;
  context.fill();
  context.stroke();
  context.restore();
};

};
</script>
<script>
var BlueRobot = function () {
  this.sprites = new Image();
  this.sprites.src = 'blue-robot.png'; // this sprite sheet has 8 cells
  this.targetMode = 'idle';
  this.walk = function () {
    this.targetMode = 'walk';
  };
  this.stop = function () {
    this.targetMode = 'idle';
  };
};

```

```

this.frameIndex = {
  'idle': [0], // first cell is the idle frame
  'walk': [1,2,3,4,5,6], // the walking animation is cells 1-6
  'stop': [7], // last cell is the stopping animation
};
this.mode = 'idle';
this.frame = 0; // index into frameIndex
this.tick = function () {
  // this advances the frame and the robot
  // the return value is how many pixels the robot has moved
  this.frame += 1;
  if (this.frame >= this.frameIndex[this.mode].length) {
    // we've reached the end of this animation cycle
    this.frame = 0;
    if (this.mode != this.targetMode) {
      // switch to next cycle
      if (this.mode == 'walk') {
        // we need to stop walking before we decide what to do next
        this.mode = 'stop';
      } else if (this.mode == 'stop') {
        if (this.targetMode == 'walk')
          this.mode = 'walk';
        else
          this.mode = 'idle';
      } else if (this.mode == 'idle') {
        if (this.targetMode == 'walk')
          this.mode = 'walk';
      }
    }
  }
}
if (this.mode == 'walk')
  return 8;
return 0;
},
this.paint = function (context, x, y) {
  if (!this.sprites.complete) return;
  // draw the right frame out of the sprite sheet onto the canvas
  // we assume each frame is as high as the sprite sheet
  // the x,y coordinates give the position of the bottom center of the sprite
  context.drawImage(this.sprites,
    this.frameIndex[this.mode][this.frame] * this.sprites.height, 0,
    this.sprites.height, this.sprites.height,
    x-this.sprites.height/2, y-this.sprites.height, this.sprites.height,
    this.sprites.height);
};
};
</script>
<script>
var canvas = document.getElementsByTagName('canvas')[0];
var context = canvas.getContext('2d');
var landscape = new Landscape(context, canvas.width, canvas.height);
var blueRobot = new BlueRobot();
// paint when the browser wants us to, using requestAnimationFrame()
function paint() {
  context.clearRect(0, 0, canvas.width, canvas.height);
  landscape.paintBackground(context, canvas.width, canvas.height);
  blueRobot.paint(context, canvas.width/2, landscape.horizon*1.1);
  landscape.paintForeground(context, canvas.width, canvas.height);
  requestAnimationFrame(paint);
}

```

```

    paint();
    // but tick every 100ms, so that we don't slow down when we don't paint
    setInterval(function () {
        var dx = blueRobot.tick();
        landscape.advance(dx);
    }, 100);
</script>
<p class="buttons">

#### 4.12.5.2 The [ImageBitmap](#)<sup>p1181</sup> rendering context <sup>§p739</sup>

##### 4.12.5.2.1 Introduction <sup>§p739</sup>

[ImageBitmapRenderingContext](#)<sup>p739</sup> is a performance-oriented interface that provides a low overhead method for displaying the contents of [ImageBitmap](#)<sup>p1181</sup> objects. It uses transfer semantics to reduce overall memory consumption. It also streamlines performance by avoiding intermediate compositing, unlike the [drawImage\(\)](#)<sup>p723</sup> method of [CanvasRenderingContext2D](#)<sup>p682</sup>.

Using an [img](#)<sup>p346</sup> element as an intermediate for getting an image resource into a canvas, for example, would result in two copies of the decoded image existing in memory at the same time: the [img](#)<sup>p346</sup> element's copy, and the one in the canvas's backing store. This memory cost can be prohibitive when dealing with extremely large images. This can be avoided by using [ImageBitmapRenderingContext](#)<sup>p739</sup>.

#### Example

Using [ImageBitmapRenderingContext](#)<sup>p739</sup>, here is how to transcode an image to the JPEG format in a memory- and CPU-efficient way:

```

createImageBitmap(inputImageBlob).then(image => {
    const canvas = document.createElement('canvas');
    const context = canvas.getContext('bitmaprenderer');
    context.transferFromImageBitmap(image);

    canvas.toBlob(outputJPEGBlob => {
        // Do something with outputJPEGBlob.
    }, 'image/jpeg');
});

```

#### 4.12.5.2.2 The [ImageBitmapRenderingContext](#)<sup>p739</sup> interface <sup>§p739</sup>

IDL

```

[Exposed=(Window,Worker)]
interface ImageBitmapRenderingContext {
    readonly attribute (HTMLCanvasElement or OffscreenCanvas) canvas;
    undefined transferFromImageBitmap(ImageBitmap? bitmap);
};

dictionary ImageBitmapRenderingContextSettings {

```

```
boolean alpha = true;
};
```

#### For web developers (non-normative)

**context** = **canvas.getContext**<sup>p679</sup>('bitmaprenderer' [, { [ **alpha**<sup>p741</sup>: false ] } ])

Returns an **ImageBitmapRenderingContext**<sup>p739</sup> object that is permanently bound to a particular **canvas**<sup>p677</sup> element.

If the **alpha**<sup>p741</sup> setting is provided and set to false, then the canvas is forced to always be opaque.

**context.canvas**<sup>p740</sup>

Returns the **canvas**<sup>p677</sup> element that the context is bound to.

**context.transferFromImageBitmap**<sup>p741</sup>(**imageBitmap**)

Transfers the underlying **bitmap data**<sup>p1182</sup> from *imageBitmap* to *context*, and the bitmap becomes the contents of the **canvas**<sup>p677</sup> element to which *context* is bound.

**context.transferFromImageBitmap**<sup>p741</sup>(**null**)

Replaces contents of the **canvas**<sup>p677</sup> element to which *context* is bound with a **transparent black** bitmap whose size corresponds to the **width**<sup>p678</sup> and **height**<sup>p678</sup> content attributes of the **canvas**<sup>p677</sup> element.

The **canvas** attribute must return the value it was initialized to when the object was created.

An **ImageBitmapRenderingContext**<sup>p739</sup> object has an **output bitmap**, which is a reference to **bitmap data**<sup>p1182</sup>.

An **ImageBitmapRenderingContext**<sup>p739</sup> object has a **bitmap mode**, which can be set to **valid** or **blank**. A value of **valid**<sup>p740</sup> indicates that the context's **output bitmap**<sup>p740</sup> refers to **bitmap data**<sup>p1182</sup> that was acquired via **transferFromImageBitmap()**<sup>p741</sup>. A value **blank**<sup>p740</sup> indicates that the context's **output bitmap**<sup>p740</sup> is a default transparent bitmap.

An **ImageBitmapRenderingContext**<sup>p739</sup> object also has an **alpha** flag, which can be set to true or false. When an **ImageBitmapRenderingContext**<sup>p739</sup> object has its **alpha**<sup>p740</sup> flag set to false, the contents of the **canvas**<sup>p677</sup> element to which the context is bound are obtained by compositing the context's **output bitmap**<sup>p740</sup> onto an **opaque black** bitmap of the same size using the **source-over** compositing operator. If the **alpha**<sup>p740</sup> flag is set to true, then the **output bitmap**<sup>p740</sup> is used as the contents of the **canvas**<sup>p677</sup> element to which the context is bound. [COMPOSITE]<sup>p1475</sup>

#### Note

*The step of compositing over an **opaque black** bitmap ought to be elided whenever equivalent results can be obtained more efficiently by other means.*

When a user agent is required to **set an ImageBitmapRenderingContext's output bitmap**, with a *context* argument that is an **ImageBitmapRenderingContext**<sup>p739</sup> object and an optional argument *bitmap* that refers to **bitmap data**<sup>p1182</sup>, it must run these steps:

1. If a *bitmap* argument was not provided, then:
  1. Set context's **bitmap mode**<sup>p740</sup> to **blank**<sup>p740</sup>.
  2. Let *canvas* be the **canvas**<sup>p677</sup> element to which *context* is bound.
  3. Set context's **output bitmap**<sup>p740</sup> to be **transparent black** with a **natural width** equal to **the numeric value**<sup>p678</sup> of *canvas*'s **width**<sup>p678</sup> attribute and a **natural height** equal to **the numeric value**<sup>p678</sup> of *canvas*'s **height**<sup>p678</sup> attribute, those values being interpreted in **CSS pixels**.
  4. Set the **output bitmap**<sup>p740</sup>'s **origin-clean**<sup>p678</sup> flag to true.
2. If a *bitmap* argument was provided, then:
  1. Set context's **bitmap mode**<sup>p740</sup> to **valid**<sup>p740</sup>.
  2. Set context's **output bitmap**<sup>p740</sup> to refer to the same underlying bitmap data as *bitmap*, without making a copy.

#### Note

*The **origin-clean**<sup>p678</sup> flag of bitmap is included in the bitmap data to be referenced by context's **output bitmap**<sup>p740</sup>.*

The **ImageBitmapRenderingContext** creation algorithm, which is passed a *target* and *options*, consists of running these steps:

1. Let *settings* be the result of [converting](#) *options* to the dictionary type [ImageBitmapRenderingContextSettings](#)<sup>p739</sup>. (This can throw an exception.)
2. Let *context* be a new [ImageBitmapRenderingContext](#)<sup>p739</sup> object.
3. Initialize *context*'s [canvas](#)<sup>p689</sup> attribute to point to *target*.
4. Set *context*'s [output bitmap](#)<sup>p740</sup> to the same bitmap as *target*'s bitmap (so that they are shared).
5. Run the steps to [set an ImageBitmapRenderingContext's output bitmap](#)<sup>p740</sup> with *context*.
6. Initialize *context*'s [alpha](#)<sup>p740</sup> flag to true.
7. Process each of the members of *settings* as follows:

**alpha**

If false, then set *context*'s [alpha](#)<sup>p740</sup> flag to false.

8. Return *context*.

The **transferFromImageBitmap(bitmap)** method, when invoked, must run these steps:

1. Let *bitmapContext* be the [ImageBitmapRenderingContext](#)<sup>p739</sup> object on which the [transferFromImageBitmap\(\)](#)<sup>p741</sup> method was called.
2. If *bitmap* is null, then run the steps to [set an ImageBitmapRenderingContext's output bitmap](#)<sup>p740</sup>, with *bitmapContext* as the *context* argument and no *bitmap* argument, then return.
3. If the value of *bitmap*'s [\[\[Detached\]\]](#)<sup>p118</sup> internal slot is set to true, then throw an ["InvalidStateError" DOMException](#).
4. Run the steps to [set an ImageBitmapRenderingContext's output bitmap](#)<sup>p740</sup>, with the *context* argument equal to *bitmapContext*, and the *bitmap* argument referring to *bitmap*'s underlying [bitmap data](#)<sup>p1182</sup>.
5. Set the value of *bitmap*'s [\[\[Detached\]\]](#)<sup>p118</sup> internal slot to true.
6. Unset *bitmap*'s [bitmap data](#)<sup>p1182</sup>.

#### 4.12.5.3 The [OffscreenCanvas](#)<sup>p741</sup> interface § p74 1

```
IDL
typedef (OffscreenCanvasRenderingContext2D or ImageBitmapRenderingContext or WebGLRenderingContext or
WebGL2RenderingContext or GPUCanvasContext) OffscreenRenderingContext;

dictionary ImageEncodeOptions {
  DOMString type = "image/png";
  unrestricted double quality;
};

enum OffscreenRenderingContextId { "2d", "bitmaprenderer", "webgl", "webgl2", "webgpu" };

[Exposed=(Window,Worker), Transferable]
interface OffscreenCanvas : EventTarget {
  constructor([EnforceRange] unsigned long long width, [EnforceRange] unsigned long long height);

  attribute [EnforceRange] unsigned long long width;
  attribute [EnforceRange] unsigned long long height;

  OffscreenRenderingContext? getContext(OffscreenRenderingContextId contextId, optional any options =
null);
  ImageBitmap transferToImageBitmap();
  Promise<Blob> convertToBlob(optional ImageEncodeOptions options = {});
```

```
attribute EventHandler oncontextlost;
attribute EventHandler oncontextrestored;
};
```

#### Note

[OffscreenCanvas<sup>p741</sup>](#) is an [EventTarget](#), so both [OffscreenCanvasRenderingContext2D<sup>p745</sup>](#) and [WebGL](#) can fire events at it. [OffscreenCanvasRenderingContext2D<sup>p745</sup>](#) can fire [contextlost<sup>p1471</sup>](#) and [contextrestored<sup>p1471</sup>](#), and [WebGL](#) can fire [webglcontextlost](#) and [webglcontextrestored](#). [\[WEBGL\]<sup>p1483</sup>](#)

[OffscreenCanvas<sup>p741</sup>](#) objects are used to create rendering contexts, much like an [HTMLCanvasElement<sup>p677</sup>](#), but with no connection to the DOM. This makes it possible to use canvas rendering contexts in [workers<sup>p1212</sup>](#).

An [OffscreenCanvas<sup>p741</sup>](#) object may hold a weak reference to a **placeholder canvas element**, which is typically in the DOM, whose embedded content is provided by the [OffscreenCanvas<sup>p741</sup>](#) object. The bitmap of the [OffscreenCanvas<sup>p741</sup>](#) object is pushed to the [placeholder canvas element<sup>p742</sup>](#) as part of the [OffscreenCanvas<sup>p741</sup>](#)'s [relevant agent<sup>p1073</sup>](#)'s [event loop<sup>p1123</sup>](#)'s [update the rendering<sup>p1128</sup>](#) steps.

#### For web developers (non-normative)

**[offscreenCanvas](#) = new [OffscreenCanvas<sup>p742</sup>](#)(width, height)**

Returns a new [OffscreenCanvas<sup>p741</sup>](#) object that is not linked to a [placeholder canvas element<sup>p742</sup>](#), and whose bitmap's size is determined by the *width* and *height* arguments.

**[context](#) = [offscreenCanvas](#).[getContext<sup>p743</sup>](#)(contextId [, options ])**

Returns an object that exposes an API for drawing on the [OffscreenCanvas<sup>p741</sup>](#) object. *contextId* specifies the desired API: "[2d<sup>p743</sup>](#)", "[bitmaprenderer<sup>p743</sup>](#)", "[webgl<sup>p743</sup>](#)", "[webgl2<sup>p743</sup>](#)", or "[webgpu<sup>p743</sup>](#)". *options* is handled by that API.

This specification defines the "[2d<sup>p688</sup>](#)" context below, which is similar but distinct from the "[2d<sup>p743</sup>](#)" context that is created from a [canvas<sup>p677</sup>](#) element. The WebGL specifications define the "[webgl<sup>p743</sup>](#)" and "[webgl2<sup>p743</sup>](#)" contexts. [WebGPU](#) defines the "[webgpu<sup>p743</sup>](#)" context. [\[WEBGL\]<sup>p1483</sup>](#) [\[WEBGPU\]<sup>p1483</sup>](#)

Returns null if the canvas has already been initialized with another context type (e.g., trying to get a "[2d<sup>p743</sup>](#)" context after getting a "[webgl<sup>p743</sup>](#)" context).

An [OffscreenCanvas<sup>p741</sup>](#) object has an internal **bitmap** that is initialized when the object is created. The width and height of the [bitmap<sup>p742</sup>](#) are equal to the values of the [width<sup>p744</sup>](#) and [height<sup>p744</sup>](#) attributes of the [OffscreenCanvas<sup>p741</sup>](#) object. Initially, all the bitmap's pixels are [transparent black](#).

An [OffscreenCanvas<sup>p741</sup>](#) object can have a rendering context bound to it. Initially, it does not have a bound rendering context. To keep track of whether it has a rendering context or not, and what kind of rendering context it is, an [OffscreenCanvas<sup>p741</sup>](#) object also has a **context mode**, which is initially **none** but can be changed to either **2d**, **bitmaprenderer**, **webgl**, **webgl2**, **webgpu**, or **detached** by algorithms defined in this specification.

The constructor **[OffscreenCanvas](#)(width, height)**, when invoked, must create a new [OffscreenCanvas<sup>p741</sup>](#) object with its [bitmap<sup>p742</sup>](#) initialized to a rectangular array of [transparent black](#) pixels of the dimensions specified by *width* and *height*; and its [width<sup>p744</sup>](#) and [height<sup>p744</sup>](#) attributes initialized to *width* and *height* respectively.

[OffscreenCanvas<sup>p741</sup>](#) objects are [transferable<sup>p118</sup>](#). Their [transfer steps<sup>p118</sup>](#), given *value* and *dataHolder*, are as follows:

1. If *value*'s [context mode<sup>p742</sup>](#) is not equal to [none<sup>p742</sup>](#), then throw an ["InvalidStateError" DOMException](#).
2. Set *value*'s [context mode<sup>p742</sup>](#) to [detached<sup>p742</sup>](#).
3. Let *width* and *height* be the dimensions of *value*'s [bitmap<sup>p742</sup>](#).
4. Unset *value*'s [bitmap<sup>p742</sup>](#).
5. Set *dataHolder*.[[Width]] to *width* and *dataHolder*.[[Height]] to *height*.
6. Set *dataHolder*.[[PlaceholderCanvas]] to be a weak reference to *value*'s [placeholder canvas element<sup>p742</sup>](#), if *value* has one, or null if it does not.

Their [transfer-receiving steps<sup>p118</sup>](#), given *dataHolder* and *value*, are:

1. Initialize *value*'s [bitmap<sup>p742</sup>](#) to a rectangular array of [transparent\\_black](#) pixels with width given by *dataHolder*.*[[Width]]* and height given by *dataHolder*.*[[Height]]*.
2. If *dataHolder*.*[[PlaceholderCanvas]]* is not null, set *value*'s [placeholder\\_canvas\\_element<sup>p742</sup>](#) to *dataHolder*.*[[PlaceholderCanvas]]* (while maintaining the weak reference semantics).

The [getContext\(contextId, options\)](#) method of an [OffscreenCanvas<sup>p741</sup>](#) object, when invoked, must run these steps:

1. If *options* is not an [object](#), then set *options* to null.
2. Set *options* to the result of [converting options](#) to a JavaScript value.
3. Run the steps in the cell of the following table whose column header matches this [OffscreenCanvas<sup>p741</sup>](#) object's [context mode<sup>p742</sup>](#) and whose row header matches *contextId*:

	<a href="#">none<sup>p742</sup></a>	<a href="#">2d<sup>p742</sup></a>	<a href="#">bitmaprenderer<sup>p742</sup></a>	<a href="#">webgl<sup>p742</sup> or webgl2<sup>p742</sup></a>	<a href="#">webgpu<sup>p742</sup></a>	<a href="#">detached<sup>p742</sup></a>
<b>"2d"</b>	<ol style="list-style-type: none"> <li>1. Let <i>context</i> be the result of running the <a href="#">offscreen 2D context creation algorithm<sup>p746</sup></a> given <i>this</i> and <i>options</i>.</li> <li>2. Set <i>this</i>'s <a href="#">context mode<sup>p742</sup></a> to <a href="#">2d<sup>p742</sup></a>.</li> <li>3. Return <i>context</i>.</li> </ol>	Return the same object as was returned the last time the method was invoked with this same first argument.	Return null.	Return null.	Return null.	Throw an <a href="#">"InvalidStateError" DOMException</a> .
<b>"bitmaprenderer"</b>	<ol style="list-style-type: none"> <li>1. Let <i>context</i> be the result of running the <a href="#">ImageBitmapRenderingContext creation algorithm<sup>p741</sup></a> given <i>this</i> and <i>options</i>.</li> <li>2. Set <i>this</i>'s <a href="#">context mode<sup>p742</sup></a> to <a href="#">bitmaprenderer<sup>p742</sup></a>.</li> <li>3. Return <i>context</i>.</li> </ol>	Return null.	Return the same object as was returned the last time the method was invoked with this same first argument.	Return null.	Return null.	Throw an <a href="#">"InvalidStateError" DOMException</a> .
<b>"webgl" or "webgl2"</b>	<ol style="list-style-type: none"> <li>1. Let <i>context</i> be the result of following the instructions given in the WebGL specifications' <i>Context Creation</i> sections. <a href="#">[WEBGL]<sup>p1483</sup></a></li> <li>2. If <i>context</i> is null, then return null; otherwise set <i>this</i>'s <a href="#">context mode<sup>p742</sup></a> to <a href="#">webgl<sup>p742</sup></a> or <a href="#">webgl2<sup>p742</sup></a>.</li> <li>3. Return <i>context</i>.</li> </ol>	Return null.	Return null.	Return the same value as was returned the last time the method was invoked with this same first argument.	Return null.	Throw an <a href="#">"InvalidStateError" DOMException</a> .
<b>"webgpu"</b>	<ol style="list-style-type: none"> <li>1. Let <i>context</i> be the result of following the instructions given in <i>WebGPU's Canvas Rendering</i> section. <a href="#">[WEBGPU]<sup>p1483</sup></a></li> <li>2. If <i>context</i> is null, then return null; otherwise set <i>this</i>'s <a href="#">context mode<sup>p742</sup></a> to <a href="#">webgpu<sup>p742</sup></a>.</li> <li>3. Return <i>context</i>.</li> </ol>	Return null.	Return null.	Return null.	Return the same value as was returned the last time the method was invoked with this same first argument.	Throw an <a href="#">"InvalidStateError" DOMException</a> .

#### For web developers (non-normative)

**`offscreenCanvas.width`**<sup>p744</sup> [ = *value* ]  
**`offscreenCanvas.height`**<sup>p744</sup> [ = *value* ]

These attributes return the dimensions of the `OffscreenCanvas`<sup>p741</sup> object's `bitmap`<sup>p742</sup>.

They can be set, to replace the `bitmap`<sup>p742</sup> with a new, `transparent black` bitmap of the specified dimensions (effectively resizing it).

If either the `width` or `height` attributes of an `OffscreenCanvas`<sup>p741</sup> object are set (to a new value or to the same value as before) and the `OffscreenCanvas`<sup>p741</sup> object's `context mode`<sup>p742</sup> is `2d`<sup>p742</sup>, then `reset the rendering context to its default state`<sup>p690</sup> and resize the `OffscreenCanvas`<sup>p741</sup> object's `bitmap`<sup>p742</sup> to the new values of the `width`<sup>p744</sup> and `height`<sup>p744</sup> attributes.

The resizing behavior for "`webgl`<sup>p743</sup>" and "`webgl2`<sup>p743</sup>" contexts is defined in the WebGL specifications. [WEBGL]<sup>p1483</sup>

The resizing behavior for "`webgpu`<sup>p743</sup>" context is defined in WebGPU. [WEBGPU]<sup>p1483</sup>

#### Note

*If an `OffscreenCanvas`<sup>p741</sup> object whose dimensions were changed has a `placeholder canvas element`<sup>p742</sup>, then the `placeholder canvas element`<sup>p742</sup>'s `natural size` will only be updated during the `OffscreenCanvas`<sup>p741</sup>'s `relevant agent`<sup>p1073</sup>'s `event loop`<sup>p1123</sup>'s `update the rendering`<sup>p1128</sup> steps.*

#### For web developers (non-normative)

**`promise = offscreenCanvas.convertToBlob`**<sup>p744</sup> ([*options*])

Returns a promise that will fulfill with a new `Blob` object representing a file containing the image in the `OffscreenCanvas`<sup>p741</sup> object.

The argument, if provided, is a dictionary that controls the encoding options of the image file to be created. The `type`<sup>p744</sup> field specifies the file format and has a default value of "`image/png`<sup>p1473</sup>"; that type is also used if the requested type isn't supported. If the image format supports variable quality (such as "`image/jpeg`<sup>p1473</sup>"), then the `quality`<sup>p744</sup> field is a number in the range 0.0 to 1.0 inclusive indicating the desired quality level for the resulting image.

**`canvas.transferToImageBitmap`**<sup>p744</sup> ()

Returns a newly created `ImageBitmap`<sup>p1181</sup> object with the image in the `OffscreenCanvas`<sup>p741</sup> object. The image in the `OffscreenCanvas`<sup>p741</sup> object is replaced with a new blank image.

The `convertToBlob(options)` method, when invoked, must run the following steps:

1. If the value of this `OffscreenCanvas`<sup>p741</sup> object's `[[Detached]]`<sup>p118</sup> internal slot is set to true, then return `a promise rejected with an "InvalidStateError" DOMException`.
2. If this `OffscreenCanvas`<sup>p741</sup> object's `context mode`<sup>p742</sup> is `2d`<sup>p742</sup> and the rendering context's `bitmap`<sup>p745</sup>'s `origin-clean`<sup>p745</sup> flag is set to false, then return `a promise rejected with a "SecurityError" DOMException`.
3. If this `OffscreenCanvas`<sup>p741</sup> object's `bitmap`<sup>p742</sup> has no pixels (i.e., either its horizontal dimension or its vertical dimension is zero) then return `a promise rejected with an "IndexSizeError" DOMException`.
4. Let *bitmap* be a copy of this `OffscreenCanvas`<sup>p741</sup> object's `bitmap`<sup>p742</sup>.
5. Let *result* be a new promise object.
6. Run these steps `in parallel`<sup>p43</sup>:
  1. Let *file* be `a serialization of bitmap as a file`<sup>p747</sup>, with *options*'s `type` and `quality` if present.
  2. `Queue an element task`<sup>p1125</sup> on the `canvas blob serialization task source`<sup>p681</sup> given the `canvas`<sup>p677</sup> element to run these steps:
    1. If *file* is null, then reject *result* with an `"EncodingError" DOMException`.
    2. Otherwise, resolve *result* with a new `Blob` object, created in the `relevant realm`<sup>p1083</sup> of this `OffscreenCanvas`<sup>p741</sup> object, representing *file*. [FILEAPI]<sup>p1478</sup>
7. Return *result*.

The `transferToImageBitmap()` method, when invoked, must run the following steps:

1. If the value of this [OffscreenCanvas](#)<sup>p741</sup> object's [\[\[Detached\]\]](#)<sup>p118</sup> internal slot is set to true, then throw an ["InvalidStateError"](#) [DOMException](#).
2. If this [OffscreenCanvas](#)<sup>p741</sup> object's [context mode](#)<sup>p742</sup> is set to [none](#)<sup>p742</sup>, then throw an ["InvalidStateError"](#) [DOMException](#).
3. Let *image* be a newly created [ImageBitmap](#)<sup>p1181</sup> object that references the same underlying bitmap data as this [OffscreenCanvas](#)<sup>p741</sup> object's [bitmap](#)<sup>p742</sup>.
4. Set this [OffscreenCanvas](#)<sup>p741</sup> object's [bitmap](#)<sup>p742</sup> to reference a newly created bitmap of the same dimensions and color space as the previous bitmap, and with its pixels initialized to [transparent black](#), or [opaque black](#) if the rendering context's [alpha](#)<sup>p745</sup> flag is set to false.

#### Note

This means that if the rendering context of this [OffscreenCanvas](#)<sup>p741</sup> is a [WebGLRenderingContext](#), the value of [preserveDrawingBuffer](#) will have no effect. [\[WEBGL\]](#)<sup>p1483</sup>

5. Return *image*.

The following are the [event handlers](#)<sup>p1136</sup> (and their corresponding [event handler event types](#)<sup>p1139</sup>) that must be supported, as [event handler IDL attributes](#)<sup>p1137</sup>, by all objects implementing the [OffscreenCanvas](#)<sup>p741</sup> interface:

Event handler <sup>p1136</sup>	Event handler event type <sup>p1139</sup>
<a href="#">oncontextlost</a>	<a href="#">contextlost</a> <sup>p1471</sup>
<a href="#">oncontextrestored</a>	<a href="#">contextrestored</a> <sup>p1471</sup>

#### 4.12.5.3.1 The offscreen 2D rendering context <sup>p74</sup><sub>5</sub>

```
IDL [Exposed=(Window,Worker)]
interface OffscreenCanvasRenderingContext2D {
  readonly attribute OffscreenCanvas canvas;
};

OffscreenCanvasRenderingContext2D includes CanvasState;
OffscreenCanvasRenderingContext2D includes CanvasTransform;
OffscreenCanvasRenderingContext2D includes CanvasCompositing;
OffscreenCanvasRenderingContext2D includes CanvasImageSmoothing;
OffscreenCanvasRenderingContext2D includes CanvasFillStrokeStyles;
OffscreenCanvasRenderingContext2D includes CanvasShadowStyles;
OffscreenCanvasRenderingContext2D includes CanvasFilters;
OffscreenCanvasRenderingContext2D includes CanvasRect;
OffscreenCanvasRenderingContext2D includes CanvasDrawPath;
OffscreenCanvasRenderingContext2D includes CanvasText;
OffscreenCanvasRenderingContext2D includes CanvasDrawImage;
OffscreenCanvasRenderingContext2D includes CanvasImageData;
OffscreenCanvasRenderingContext2D includes CanvasPathDrawingStyles;
OffscreenCanvasRenderingContext2D includes CanvasTextDrawingStyles;
OffscreenCanvasRenderingContext2D includes CanvasPath;
```

The [OffscreenCanvasRenderingContext2D](#)<sup>p745</sup> object is a rendering context for drawing to the [bitmap](#)<sup>p742</sup> of an [OffscreenCanvas](#)<sup>p741</sup> object. It is similar to the [CanvasRenderingContext2D](#)<sup>p682</sup> object, with the following differences:

- there is no support for [user interface](#)<sup>p684</sup> features;
- its [canvas](#)<sup>p746</sup> attribute refers to an [OffscreenCanvas](#)<sup>p741</sup> object rather than a [canvas](#)<sup>p677</sup> element;

An [OffscreenCanvasRenderingContext2D](#)<sup>p745</sup> object has a **bitmap** that is initialized when the object is created.

The [bitmap](#)<sup>p745</sup> has an **origin-clean** flag, which can be set to true or false. Initially, when one of these bitmaps is created, its [origin-clean](#)<sup>p745</sup> flag must be set to true.

An [OffscreenCanvasRenderingContext2D](#)<sup>p745</sup> object also has an **alpha** flag, which can be set to true or false. Initially, when the

context is created, its alpha flag must be set to true. When an [OffscreenCanvasRenderingContext2D](#)<sup>p745</sup> object has its [alpha](#)<sup>p745</sup> flag set to false, then its alpha channel must be fixed to 1.0 (fully opaque) for all pixels, and attempts to change the alpha component of any pixel must be silently ignored.

An [OffscreenCanvasRenderingContext2D](#)<sup>p745</sup> object also has a **color space** setting of type [PredefinedColorSpace](#)<sup>p682</sup>. The color space for the context's [bitmap](#)<sup>p745</sup> is set to the context's [color space](#)<sup>p746</sup>.

An [OffscreenCanvasRenderingContext2D](#)<sup>p745</sup> object has an **associated OffscreenCanvas object**, which is the [OffscreenCanvas](#)<sup>p741</sup> object from which the [OffscreenCanvasRenderingContext2D](#)<sup>p745</sup> object was created.

For web developers (non-normative)

```
offscreenCanvas = offscreenCanvasRenderingContext2D.canvasp746  
Returns the associated OffscreenCanvas objectp746.
```

The **offscreen 2D context creation algorithm**, which is passed a *target* (an [OffscreenCanvas](#)<sup>p741</sup> object) and optionally some arguments, consists of running the following steps:

1. If the algorithm was passed some arguments, let *arg* be the first such argument. Otherwise, let *arg* be undefined.
2. Let *settings* be the result of [converting](#) *arg* to the dictionary type [CanvasRenderingContext2DSettings](#)<sup>p682</sup>. (This can throw an exception.).
3. Let *context* be a new [OffscreenCanvasRenderingContext2D](#)<sup>p745</sup> object.
4. Set *context*'s [associated OffscreenCanvas object](#)<sup>p746</sup> to *target*.
5. If *settings*["[alpha](#)<sup>p688</sup>"] is false, then set *context*'s [alpha](#)<sup>p745</sup> flag to false.
6. Set *context*'s [color space](#)<sup>p746</sup> to *settings*["[colorSpace](#)<sup>p688</sup>"].
7. Set *context*'s [bitmap](#)<sup>p745</sup> to a newly created bitmap with the dimensions specified by the [width](#)<sup>p744</sup> and [height](#)<sup>p744</sup> attributes of *target*, and set *target*'s bitmap to the same bitmap (so that they are shared).
8. If *context*'s [alpha](#)<sup>p745</sup> flag is set to true, initialize all the pixels of *context*'s [bitmap](#)<sup>p745</sup> to [transparent black](#). Otherwise, initialize the pixels to [opaque black](#).
9. Return *context*.

#### Note

Implementations are encouraged to short-circuit the graphics update steps of the [window event loop](#)<sup>p1123</sup> for the purposes of updating the contents of a [placeholder canvas element](#)<sup>p742</sup> to the display. This could mean, for example, that the bitmap contents are copied directly to a graphics buffer that is mapped to the physical display location of the [placeholder canvas element](#)<sup>p742</sup>. This or similar short-circuiting approaches can significantly reduce display latency, especially in cases where the [OffscreenCanvas](#)<sup>p741</sup> is updated from a [worker event loop](#)<sup>p1123</sup> and the [window event loop](#)<sup>p1123</sup> of the [placeholder canvas element](#)<sup>p742</sup> is busy. However, such shortcuts cannot have any script-observable side-effects. This means that the committed bitmap still needs to be sent to the [placeholder canvas element](#)<sup>p742</sup>, in case the element is used as a [CanvasImageSource](#)<sup>p682</sup>, as an [ImageBitmapSource](#)<sup>p1181</sup>, or in case [toDataURL\(\)](#)<sup>p681</sup> or [toBlob\(\)](#)<sup>p681</sup> are called on it.

The **canvas** attribute, on getting, must return this [OffscreenCanvasRenderingContext2D](#)<sup>p745</sup>'s [associated OffscreenCanvas object](#)<sup>p746</sup>.

#### 4.12.5.4 Color spaces and color space conversion <sup>p74</sup><sub>6</sub>

The [canvas](#)<sup>p677</sup> APIs provide mechanisms for specifying the color space of the canvas's backing store. The default backing store color space for all canvas APIs is '[srgb](#)'.

[Color space conversion](#) must be applied to the canvas's backing store when rendering the canvas to the output device. This color space conversion must be identical to the color space conversion that would be applied to an [img](#)<sup>p346</sup> element with a color profile that specifies the same [color space](#)<sup>p688</sup> as the canvas's backing store.

When drawing content to a 2D context, all inputs must be [converted](#) to the [context's color space](#)<sup>p688</sup> before drawing. Interpolation of gradient color stops must be performed on color values after conversion to the [context's color space](#)<sup>p688</sup>. Alpha blending must be performed on values after conversion to the [context's color space](#)<sup>p688</sup>.

## Note

There do not exist any inputs to a 2D context for which the color space is undefined. The color space for CSS colors is defined in CSS Color. The color space for images that specify no color profile information is assumed to be 'srgb', as specified in the [Color Spaces of Untagged Colors](#) section of CSS Color. [\[CSSCOLOR\]](#)<sup>p1476</sup>

### 4.12.5.5 Serializing bitmaps to a file <sup>§ p74</sup><sub>7</sub>

When a user agent is to create **a serialization of the bitmap as a file**, given a *type* and an optional *quality*, it must create an image file in the format given by *type*. If an error occurs during the creation of the image file (e.g. an internal encoder error), then the result of the serialization is null. [\[PNG\]](#)<sup>p1481</sup>

The image file's pixel data must be the bitmap's pixel data scaled to one image pixel per coordinate space unit, and if the file format used supports encoding resolution metadata, the resolution must be given as 96dpi (one image pixel per [CSS pixel](#)).

If *type* is supplied, then it must be interpreted as a [MIME type](#) giving the format to use. If the type has any parameters, then it must be treated as not supported.

## Example

For example, the value "[image/png](#)<sup>p1473</sup>" would mean to generate a PNG image, the value "[image/jpeg](#)<sup>p1473</sup>" would mean to generate a JPEG image, and the value "[image/svg+xml](#)<sup>p1473</sup>" would mean to generate an SVG image (which would require that the user agent track how the bitmap was generated, an unlikely, though potentially awesome, feature).

User agents must support PNG ("[image/png](#)<sup>p1473</sup>"). User agents may support other types. If the user agent does not support the requested type, then it must create the file using the PNG format. [\[PNG\]](#)<sup>p1481</sup>

User agents must [convert the provided type to ASCII lowercase](#) before establishing if they support that type.

For image types that do not support an alpha channel, the serialized image must be the bitmap image composited onto an [opaque black](#) background using the [source-over](#) compositing operator.

For image types that support color profiles, the serialized image must include a color profile indicating the color space of the underlying bitmap. For image types that do not support color profiles, the serialized image must be [converted](#) to the 'srgb' color space using 'relative-colorimetric' rendering intent.

## Note

Thus, in the 2D context, calling the [drawImage\(\)](#)<sup>p723</sup> method to render the output of the [toDataURL\(\)](#)<sup>p681</sup> or [toBlob\(\)](#)<sup>p681</sup> method to the canvas, given the appropriate dimensions, has no visible effect beyond, at most, clipping colors of the canvas to a more narrow gamut.

If *type* is an image format that supports variable quality (such as "[image/jpeg](#)<sup>p1473</sup>"), *quality* is given, and *type* is not "[image/png](#)<sup>p1473</sup>", then, if *quality* is a [Number](#) in the range 0.0 to 1.0 inclusive, the user agent must treat *quality* as the desired quality level. Otherwise, the user agent must use its default quality value, as if the *quality* argument had not been given.

## Note

The use of type-testing here, instead of simply declaring *quality* as a Web IDL double, is a historical artifact.

## Note

Different implementations can have slightly different interpretations of "quality". When the quality is not specified, an implementation-specific default is used that represents a reasonable compromise between compression ratio, image quality, and encoding time.

### 4.12.5.6 Security with [canvas](#)<sup>p677</sup> elements <sup>§ p74</sup><sub>7</sub>

This section is non-normative.

**Information leakage** can occur if scripts from one [origin](#)<sup>p898</sup> can access information (e.g. read pixels) from images from another origin

(one that isn't the [same](#)<sup>p899</sup>).

To mitigate this, bitmaps used with [canvas](#)<sup>p677</sup> elements, [OffscreenCanvas](#)<sup>p741</sup> objects, and [ImageBitmap](#)<sup>p1181</sup> objects are defined to have a flag indicating whether they are [origin-clean](#)<sup>p678</sup>. All bitmaps start with their [origin-clean](#)<sup>p678</sup> set to true. The flag is set to false when cross-origin images are used.

The [toDataURL\(\)](#)<sup>p681</sup>, [toBlob\(\)](#)<sup>p681</sup>, and [getImageData\(\)](#)<sup>p727</sup> methods check the flag and will throw a ["SecurityError" DOMException](#) rather than leak cross-origin data.

The value of the [origin-clean](#)<sup>p678</sup> flag is propagated from a source's bitmap to a new [ImageBitmap](#)<sup>p1181</sup> object by [createImageBitmap\(\)](#)<sup>p1182</sup>. Conversely, a destination [canvas](#)<sup>p677</sup> element's bitmap will have its [origin-clean](#)<sup>p678</sup> flags set to false by [drawImage](#)<sup>p723</sup> if the source image is an [ImageBitmap](#)<sup>p1181</sup> object whose bitmap has its [origin-clean](#)<sup>p678</sup> flag set to false.

The flag can be reset in certain situations; for example, when changing the value of the [width](#)<sup>p678</sup> or the [height](#)<sup>p678</sup> content attribute of the [canvas](#)<sup>p677</sup> element to which a [CanvasRenderingContext2D](#)<sup>p682</sup> is bound, the bitmap is cleared and its [origin-clean](#)<sup>p678</sup> flag is reset.

When using an [ImageBitmapRenderingContext](#)<sup>p739</sup>, the value of the [origin-clean](#)<sup>p678</sup> flag is propagated from [ImageBitmap](#)<sup>p1181</sup> objects when they are transferred to the [canvas](#)<sup>p677</sup> via [transferFromImageBitmap\(\)](#)<sup>p741</sup>.

4.12.5.7 Premultiplied alpha and the 2D rendering context <sup>§p748</sup>

**Premultiplied alpha** refers to one way of representing transparency in an image, the other being non-premultiplied alpha.

Under non-premultiplied alpha, the red, green, and blue channels of a pixel represent that pixel's color, and its alpha channel represents that pixel's opacity.

Under premultiplied alpha, however, the red, green, and blue channels of a pixel represent the amounts of color that the pixel adds to the image, and its alpha channel represents the amount that the pixel obscures whatever is behind it.

Example

For instance, assuming the color channels range from 0 (off) to 255 (full intensity), these example colors are represented in the following ways:

CSS color representation	Premultiplied representation	Non-premultiplied representation	Description of color	Image of color blended above other content
rgba(255, 127, 0, 1)	255, 127, 0, 255	255, 127, 0, 255	Completely-opaque orange	
rgba(255, 255, 0, 0.5)	127, 127, 0, 127	255, 255, 0, 127	Halfway-opaque yellow	
Unrepresentable	255, 127, 0, 127	Unrepresentable	Additive halfway-opaque orange	

CSS color representation	Premultiplied representation	Non-premultiplied representation	Description of color	Image of color blended above other content
Unrepresentable	255, 127, 0, 0	Unrepresentable	Additive fully-transparent orange	
rgba(255, 127, 0, 0)	0, 0, 0, 0	255, 127, 0, 0	Fully-transparent ("invisible") orange	
rgba(0, 127, 255, 0)	0, 0, 0, 0	255, 127, 0, 0	Fully-transparent ("invisible") turquoise	

**Converting a color value from a non-premultiplied representation to a premultiplied one** involves multiplying the color's red, green, and blue channels by its alpha channel (remapping the range of the alpha channel such that "fully transparent" is 0, and "fully opaque" is 1).

**Converting a color value from a premultiplied representation to a non-premultiplied one** involves the inverse: dividing the color's red, green, and blue channels by its alpha channel.

As certain colors can only be represented under premultiplied alpha (for instance, additive colors), and others can only be represented under non-premultiplied alpha (for instance, "invisible" colors which hold certain red, green, and blue values even with no opacity); and division and multiplication on 8-bit integers (which is how canvas's colors are currently stored) entails a loss of precision, converting between premultiplied and non-premultiplied alpha is a lossy operation on colors that are not fully opaque.

A [CanvasRenderingContext2D](#)<sup>p682</sup>'s [output bitmap](#)<sup>p687</sup> and an [OffscreenCanvasRenderingContext2D](#)<sup>p745</sup>'s [bitmap](#)<sup>p745</sup> must use premultiplied alpha to represent transparent colors.

#### Note

*It is important for canvas bitmaps to represent colors using premultiplied alpha because it affects the range of representable colors. While additive colors cannot currently be drawn onto canvases directly because CSS colors are non-premultiplied and cannot represent them, it is still possible to, for instance, draw additive colors onto a WebGL canvas and then draw that WebGL canvas onto a 2D canvas via [drawImage\(\)](#)<sup>p723</sup>.*

## 4.13 Custom elements <sup>p74</sup><sub>9</sub>

### 4.13.1 Introduction <sup>p74</sup><sub>9</sub>

*This section is non-normative.*

[Custom elements](#)<sup>p759</sup> provide a way for authors to build their own fully-featured DOM elements. Although authors could always use non-standard elements in their documents, with application-specific behavior added after the fact by scripting or similar, such elements have historically been non-conforming and not very functional. By [defining](#)<sup>p762</sup> a custom element, authors can inform the parser how to properly construct an element and how elements of that class should react to changes.

Custom elements are part of a larger effort to "rationalise the platform", by explaining existing platform features (like the elements of HTML) in terms of lower-level author-exposed extensibility points (like custom element definition). Although today there are many limitations on the capabilities of custom elements—both functionally and semantically—that prevent them from fully explaining the behaviors of HTML's existing elements, we hope to shrink this gap over time.

#### 4.13.1.1 Creating an autonomous custom element <sup>§p75</sup><sub>0</sub>

*This section is non-normative.*

For the purposes of illustrating how to create an [autonomous custom element](#)<sup>p759</sup>, let's define a custom element that encapsulates rendering a small icon for a country flag. Our goal is to be able to use it like so:

```
<flag-icon country="nl"></flag-icon>
```

To do this, we first declare a class for the custom element, extending [HTMLElement](#)<sup>p142</sup>:

```
class FlagIcon extends HTMLElement {
  constructor() {
    super();
    this._countryCode = null;
  }

  static observedAttributes = ["country"];

  attributeChangedCallback(name, oldValue, newValue) {
    // name will always be "country" due to observedAttributes
    this._countryCode = newValue;
    this._updateRendering();
  }

  connectedCallback() {
    this._updateRendering();
  }

  get country() {
    return this._countryCode;
  }
  set country(v) {
    this.setAttribute("country", v);
  }

  _updateRendering() {
    // Left as an exercise for the reader. But, you'll probably want to
    // check this.ownerDocument.defaultView to see if we've been
    // inserted into a document with a browsing context, and avoid
    // doing any work if not.
  }
}
```

We then need to use this class to define the element:

```
customElements.define("flag-icon", FlagIcon);
```

At this point, our above code will work! The parser, whenever it sees the `flag-icon` tag, will construct a new instance of our `FlagIcon` class, and tell our code about its new `country` attribute, which we then use to set the element's internal state and update its rendering (when appropriate).

You can also create `flag-icon` elements using the DOM API:

```
const flagIcon = document.createElement("flag-icon")
flagIcon.country = "jp"
```

```
document.body.appendChild(flagIcon)
```

Finally, we can also use the [custom element constructor](#)<sup>p759</sup> itself. That is, the above code is equivalent to:

```
const flagIcon = new FlagIcon()
flagIcon.country = "jp"
document.body.appendChild(flagIcon)
```

#### 4.13.1.2 Creating a form-associated custom element <sup>§p75</sup>

*This section is non-normative.*

Adding a static `formAssociated` property, with a true value, makes an [autonomous custom element](#)<sup>p759</sup> a [form-associated custom element](#)<sup>p760</sup>. The [ElementInternals](#)<sup>p771</sup> interface helps you to implement functions and properties common to form control elements.

```
class MyCheckbox extends HTMLElement {
  static formAssociated = true;
  static observedAttributes = ['checked'];

  constructor() {
    super();
    this._internals = this.attachInternals();
    this.addEventListener('click', this._onClick.bind(this));
  }

  get form() { return this._internals.form; }
  get name() { return this.getAttribute('name'); }
  get type() { return this.localName; }

  get checked() { return this.hasAttribute('checked'); }
  set checked(flag) { this.toggleAttribute('checked', Boolean(flag)); }

  attributeChangedCallback(name, oldValue, newValue) {
    // name will always be "checked" due to observedAttributes
    this._internals.setFormValue(this.checked ? 'on' : null);
  }

  _onClick(event) {
    this.checked = !this.checked;
  }
}
customElements.define('my-checkbox', MyCheckbox);
```

You can use the custom element `my-checkbox` like a built-in form-associated element. For example, putting it in [form](#)<sup>p514</sup> or [label](#)<sup>p518</sup> associates the `my-checkbox` element with them, and submitting the [form](#)<sup>p514</sup> will send data provided by `my-checkbox` implementation.

```
<form action="..." method="...">
  <label><my-checkbox name="agreed"></my-checkbox> I read the agreement.</label>
  <input type="submit">
</form>
```

#### 4.13.1.3 Creating a custom element with default accessible roles, states, and properties <sup>§p75</sup>

*This section is non-normative.*

By using the appropriate properties of [ElementInternals](#)<sup>p771</sup>, your custom element can have default accessibility semantics. The following code expands our form-associated checkbox from the previous section to properly set its default role and checkedness, as

viewed by accessibility technology:

```
class MyCheckbox extends HTMLElement {
  static formAssociated = true;
  static observedAttributes = ['checked'];

  constructor() {
    super();
    this._internals = this.attachInternals();
    this.addEventListener('click', this._onClick.bind(this));

    this._internals.role = 'checkbox';
    this._internals.ariaChecked = 'false';
  }

  get form() { return this._internals.form; }
  get name() { return this.getAttribute('name'); }
  get type() { return this.localName; }

  get checked() { return this.hasAttribute('checked'); }
  set checked(flag) { this.toggleAttribute('checked', Boolean(flag)); }

  attributeChangedCallback(name, oldValue, newValue) {
    // name will always be "checked" due to observedAttributes
    this._internals.setFormValue(this.checked ? 'on' : null);
    this._internals.ariaChecked = this.checked;
  }

  _onClick(event) {
    this.checked = !this.checked;
  }
}

customElements.define('my-checkbox', MyCheckbox);
```

Note that, like for built-in elements, these are only defaults, and can be overridden by the page author using the [role<sup>p68</sup>](#) and [aria-\\*<sup>p68</sup>](#) attributes:

```
<!-- This markup is non-conforming -->
<input type="checkbox" checked role="button" aria-checked="false">
```

```
<!-- This markup is probably not what the custom element author intended -->
<my-checkbox role="button" checked aria-checked="false">
```

Custom element authors are encouraged to state what aspects of their accessibility semantics are strong native semantics, i.e., should not be overridden by users of the custom element. In our example, the author of the `my-checkbox` element would state that its [role](#) and [aria-checked](#) values are strong native semantics, thus discouraging code such as the above.

#### 4.13.1.4 Creating a customized built-in element <sup>§p75</sup><sub>2</sub>

*This section is non-normative.*

[Customized built-in elements<sup>p759</sup>](#) are a distinct kind of [custom element<sup>p759</sup>](#), which are defined slightly differently and used very differently compared to [autonomous custom elements<sup>p759</sup>](#). They exist to allow reuse of behaviors from the existing elements of HTML, by extending those elements with new custom functionality. This is important since many of the existing behaviors of HTML elements can unfortunately not be duplicated by using purely [autonomous custom elements<sup>p759</sup>](#). Instead, [customized built-in elements<sup>p759</sup>](#) allow the installation of custom construction behavior, lifecycle hooks, and prototype chain onto existing elements, essentially "mixing in" these capabilities on top of the already-existing element.

[Customized built-in elements<sup>p759</sup>](#) require a distinct syntax from [autonomous custom elements<sup>p759</sup>](#) because user agents and other software key off an element's local name in order to identify the element's semantics and behavior. That is, the concept of [customized](#)

[built-in elements](#)<sup>p759</sup> building on top of existing behavior depends crucially on the extended elements retaining their original local name.

In this example, we'll be creating a [customized built-in element](#)<sup>p759</sup> named `plastic-button`, which behaves like a normal button but gets fancy animation effects added whenever you click on it. We start by defining a class, just like before, although this time we extend [HTMLButtonElement](#)<sup>p566</sup> instead of [HTMLElement](#)<sup>p142</sup>:

```
class PlasticButton extends HTMLButtonElement {
  constructor() {
    super();

    this.addEventListener("click", () => {
      // Draw some fancy animation effects!
    });
  }
}
```

When defining our custom element, we have to also specify the `extends` option:

```
customElements.define("plastic-button", PlasticButton, { extends: "button" });
```

In general, the name of the element being extended cannot be determined simply by looking at what element interface it extends, as many elements share the same interface (such as [q](#)<sup>p266</sup> and [blockquote](#)<sup>p235</sup> both sharing [HTMLQuoteElement](#)<sup>p235</sup>).

To construct our [customized built-in element](#)<sup>p759</sup> from parsed HTML source text, we use the `is`<sup>p759</sup> attribute on a [button](#)<sup>p566</sup> element:

```
<button is="plastic-button">Click Me!</button>
```

Trying to use a [customized built-in element](#)<sup>p759</sup> as an [autonomous custom element](#)<sup>p759</sup> will *not* work; that is, `<plastic-button>Click me?</plastic-button>` will simply create an [HTMLElement](#)<sup>p142</sup> with no special behavior.

If you need to create a customized built-in element programmatically, you can use the following form of [createElement\(\)](#):

```
const plasticButton = document.createElement("button", { is: "plastic-button" });
plasticButton.textContent = "Click me!";
```

And as before, the constructor will also work:

```
const plasticButton2 = new PlasticButton();
console.log(plasticButton2.localName); // will output "button"
console.assert(plasticButton2 instanceof PlasticButton);
console.assert(plasticButton2 instanceof HTMLButtonElement);
```

Note that when creating a customized built-in element programmatically, the `is`<sup>p759</sup> attribute will not be present in the DOM, since it was not explicitly set. However, [it will be added to the output when serializing](#)<sup>p1372</sup>:

```
console.assert(!plasticButton.hasAttribute("is"));
console.log(plasticButton.outerHTML); // will output '<button is="plastic-button"></button>'
```

Regardless of how it is created, all of the ways in which [button](#)<sup>p566</sup> is special apply to such "plastic buttons" as well: their focus behavior, ability to participate in [form submission](#)<sup>p629</sup>, the [disabled](#)<sup>p601</sup> attribute, and so on.

[Customized built-in elements](#)<sup>p759</sup> are designed to allow extension of existing HTML elements that have useful user-agent supplied behavior or APIs. As such, they can only extend existing HTML elements defined in this specification, and cannot extend legacy elements such as [bgsound](#)<sup>p1426</sup>, [blink](#)<sup>p1427</sup>, [isindex](#)<sup>p1426</sup>, [keygen](#)<sup>p1426</sup>, [multicol](#)<sup>p1427</sup>, [nextid](#)<sup>p1426</sup>, or [spacer](#)<sup>p1427</sup> that have been defined to use [HTMLUnknownElement](#)<sup>p142</sup> as their [element interface](#).

One reason for this requirement is future-compatibility: if a [customized built-in element](#)<sup>p759</sup> was defined that extended a currently-unknown element, for example `combobox`, this would prevent this specification from defining a `combobox` element in the future, as consumers of the derived [customized built-in element](#)<sup>p759</sup> would have come to depend on their base element having no interesting user-agent-supplied behavior.

#### 4.13.1.5 Drawbacks of autonomous custom elements <sup>§ p75</sup><sub>4</sub>

*This section is non-normative.*

As specified below, and alluded to above, simply defining and using an element called `taco-button` does not mean that such elements [represent](#)<sup>p141</sup> buttons. That is, tools such as web browsers, search engines, or accessibility technology will not automatically treat the resulting element as a button just based on its defined name.

To convey the desired button semantics to a variety of users, while still using an [autonomous custom element](#)<sup>p759</sup>, a number of techniques would need to be employed:

- The addition of the [tabindex](#)<sup>p838</sup> attribute would make the `taco-button` [focusable](#)<sup>p837</sup>. Note that if the `taco-button` were to become logically disabled, the [tabindex](#)<sup>p838</sup> attribute would need to be removed.
- The addition of an ARIA role and various ARIA states and properties helps convey semantics to accessibility technology. For example, setting the [role](#) to `"button"` will convey the semantics that this is a button, enabling users to successfully interact with the control using usual button-like interactions in their accessibility technology. Setting the [aria-label](#) property is necessary to give the button an [accessible name](#), instead of having accessibility technology traverse its child text nodes and announce them. And setting the [aria-disabled](#) state to `"true"` when the button is logically disabled conveys to accessibility technology the button's disabled state.
- The addition of event handlers to handle commonly-expected button behaviors helps convey the semantics of the button to web browser users. In this case, the most relevant event handler would be one that proxies appropriate [keydown](#) events to become [click](#) events, so that you can activate the button both with keyboard and by clicking.
- In addition to any default visual styling provided for `taco-button` elements, the visual styling will also need to be updated to reflect changes in logical state, such as becoming disabled; that is, whatever style sheet has rules for `taco-button` will also need to have rules for `taco-button[disabled]`.

With these points in mind, a full-featured `taco-button` that took on the responsibility of conveying button semantics (including the ability to be disabled) might look something like this:

```
class TacoButton extends HTMLElement {
  static observedAttributes = ["disabled"];

  constructor() {
    super();
    this._internals = this.attachInternals();
    this._internals.role = "button";

    this.addEventListener("keydown", e => {
      if (e.code === "Enter" || e.code === "Space") {
        this.dispatchEvent(new PointerEvent("click", {
          bubbles: true,
          cancelable: true
        }));
      }
    });

    this.addEventListener("click", e => {
      if (this.disabled) {
        e.preventDefault();
        e.stopImmediatePropagation();
      }
    });

    this._observer = new MutationObserver(() => {
      this._internals.ariaLabel = this.textContent;
    });
  }

  connectedCallback() {
    this.setAttribute("tabindex", "0");
  }
}
```

```

    this._observer.observe(this, {
      childList: true,
      characterData: true,
      subtree: true
    });
  }

  disconnectedCallback() {
    this._observer.disconnect();
  }

  get disabled() {
    return this.hasAttribute("disabled");
  }

  set disabled(flag) {
    this.toggleAttribute("disabled", Boolean(flag));
  }

  attributeChangedCallback(name, oldValue, newValue) {
    // name will always be "disabled" due to observedAttributes
    if (this.disabled) {
      this.removeAttribute("tabindex");
      this._internals.ariaDisabled = "true";
    } else {
      this.setAttribute("tabindex", "0");
      this._internals.ariaDisabled = "false";
    }
  }
}

```

Even with this rather-complicated element definition, the element is not a pleasure to use for consumers: it will be continually "sprouting" [tabindex](#)<sup>p838</sup> attributes of its own volition, and its choice of `tabindex="0"` focusability behavior may not match the [button](#)<sup>p566</sup> behavior on the current platform. This is because as of now there is no way to specify default focus behavior for custom elements, forcing the use of the [tabindex](#)<sup>p838</sup> attribute to do so (even though it is usually reserved for allowing the consumer to override default behavior).

In contrast, a simple [customized built-in element](#)<sup>p759</sup>, as shown in the previous section, would automatically inherit the semantics and behavior of the [button](#)<sup>p566</sup> element, with no need to implement these behaviors manually. In general, for any elements with nontrivial behavior and semantics that build on top of existing elements of HTML, [customized built-in elements](#)<sup>p759</sup> will be easier to develop, maintain, and consume.

#### 4.13.1.6 Upgrading elements after their creation <sup>p75</sup><sub>s</sub>

*This section is non-normative.*

Because [element definition](#)<sup>p762</sup> can occur at any time, a non-custom element could be [created](#), and then later become a [custom element](#)<sup>p759</sup> after an appropriate [definition](#)<sup>p761</sup> is registered. We call this process "upgrading" the element, from a normal element into a custom element.

[Upgrades](#)<sup>p765</sup> enable scenarios where it may be preferable for [custom element definitions](#)<sup>p761</sup> to be registered after relevant elements have been initially created, such as by the parser. They allow progressive enhancement of the content in the custom element. For example, in the following HTML document the element definition for `img-viewer` is loaded asynchronously:

```

<!DOCTYPE html>
<html lang="en">
<title>Image viewer example</title>

<img-viewer filter="Kelvin">
  
</img-viewer>

```

```
<script src="js/elements/img-viewer.js" async></script>
```

The definition for the `img-viewer` element here is loaded using a `script`<sup>p652</sup> element marked with the `async`<sup>p654</sup> attribute, placed after the `<img-viewer>` tag in the markup. While the script is loading, the `img-viewer` element will be treated as an undefined element, similar to a `span`<sup>p298</sup>. Once the script loads, it will define the `img-viewer` element, and the existing `img-viewer` element on the page will be upgraded, applying the custom element's definition (which presumably includes applying an image filter identified by the string "Kelvin", enhancing the image's visual appearance).

Note that `upgrades`<sup>p765</sup> only apply to elements in the document tree. (Formally, elements that are `connected`.) An element that is not inserted into a document will stay un-upgraded. An example illustrates this point:

```
<!DOCTYPE html>
<html lang="en">
<title>Upgrade edge-cases example</title>

<example-element></example-element>

<script>
  "use strict";

  const inDocument = document.querySelector("example-element");
  const outOfDocument = document.createElement("example-element");

  // Before the element definition, both are HTMLElement:
  console.assert(inDocument instanceof HTMLElement);
  console.assert(outOfDocument instanceof HTMLElement);

  class ExampleElement extends HTMLElement {}
  customElements.define("example-element", ExampleElement);

  // After element definition, the in-document element was upgraded:
  console.assert(inDocument instanceof ExampleElement);
  console.assert(!(outOfDocument instanceof ExampleElement));

  document.body.appendChild(outOfDocument);

  // Now that we've moved the element into the document, it too was upgraded:
  console.assert(outOfDocument instanceof ExampleElement);
</script>
```

#### 4.13.1.7 Exposing custom element states §<sup>p75</sup><sub>6</sub>

Built-in elements provided by user agents have certain states that can change over time depending on user interaction and other factors, and are exposed to web authors through `pseudo-classes`. For example, some form controls have the "invalid" state, which is exposed through the `:invalid`<sup>p785</sup> `pseudo-class`.

Like built-in elements, `custom elements`<sup>p759</sup> can have various states to be in too, and `custom element`<sup>p759</sup> authors want to expose these states in a similar fashion as the built-in elements.

This is done via the `:state()`<sup>p786</sup> `pseudo-class`. A custom element author can use the `states`<sup>p775</sup> property of `ElementInternals`<sup>p771</sup> to add and remove such custom states, which are then exposed as arguments to the `:state()`<sup>p786</sup> `pseudo-class`.

#### Example

The following shows how `:state()`<sup>p786</sup> can be used to style a custom checkbox element. Assume that `LabeledCheckbox` doesn't expose its "checked" state via a content attribute.

```
<script>
```

```

class LabeledCheckbox extends HTMLElement {
  constructor() {
    super();
    this._internals = this.attachInternals();
    this.addEventListener('click', this._onClick.bind(this));

    const shadowRoot = this.attachShadow({mode: 'closed'});
    shadowRoot.innerHTML =
      `<style>
        :host::before {
          content: '[ ]';
          white-space: pre;
          font-family: monospace;
        }
        :host(:state:checked)::before { content: '[x]' }
      </style>
      <slot>Label</slot>`;
  }

  get checked() { return this._internals.states.has('checked'); }

  set checked(flag) {
    if (flag)
      this._internals.states.add('checked');
    else
      this._internals.states.delete('checked');
  }

  _onClick(event) {
    this.checked = !this.checked;
  }
}

customElements.define('labeled-checkbox', LabeledCheckbox);
</script>

<style>
labeled-checkbox { border: dashed red; }
labeled-checkbox:state:checked { border: solid; }
</style>

<labeled-checkbox>You need to check this</labeled-checkbox>

```

### Example

Custom pseudo-classes can even target shadow parts. An extension of the above example shows this:

```

<script>
class QuestionBox extends HTMLElement {
  constructor() {
    super();
    const shadowRoot = this.attachShadow({mode: 'closed'});
    shadowRoot.innerHTML =
      `<div><slot>Question</slot></div>
      <labeled-checkbox part='checkbox'>Yes</labeled-checkbox>`;
  }
}
customElements.define('question-box', QuestionBox);
</script>

```

```

<style>
question-box::part(checkbox) { color: red; }
question-box::part(checkbox):state:checked { color: green; }
</style>

<question-box>Continue?</question-box>

```

#### 4.13.2 Requirements for custom element constructors and reactions §<sup>p75</sup>

When authoring [custom element constructors](#)<sup>p759</sup>, authors are bound by the following conformance requirements:

- A parameter-less call to `super()` must be the first statement in the constructor body, to establish the correct prototype chain and **this** value before any further code is run.
- A `return` statement must not appear anywhere inside the constructor body, unless it is a simple early-return (`return` or `return this`).
- The constructor must not use the [document.write\(\)](#)<sup>p1153</sup> or [document.open\(\)](#)<sup>p1151</sup> methods.
- The element's attributes and children must not be inspected, as in the non-[upgrade](#)<sup>p765</sup> case none will be present, and relying on upgrades makes the element less usable.
- The element must not gain any attributes or children, as this violates the expectations of consumers who use the [createElement](#) or [createElementNS](#) methods.
- In general, work should be deferred to `connectedCallback` as much as possible—especially work involving fetching resources or rendering. However, note that `connectedCallback` can be called more than once, so any initialization work that is truly one-time will need a guard to prevent it from running twice.
- In general, the constructor should be used to set up initial state and default values, and to set up event listeners and possibly a [shadow root](#).

Several of these requirements are checked during [element creation](#), either directly or indirectly, and failing to follow them will result in a custom element that cannot be instantiated by the parser or DOM APIs. This is true even if the work is done inside a constructor-initiated [microtask](#)<sup>p1124</sup>, as a [microtask checkpoint](#)<sup>p1131</sup> can occur immediately after construction.

When authoring [custom element reactions](#)<sup>p768</sup>, authors should avoid manipulating the node tree as this can lead to unexpected results.

#### Example

An element's `connectedCallback` can be queued before the element is disconnected, but as the callback queue is still processed, it results in a `connectedCallback` for an element that is no longer connected:

```

class CParent extends HTMLElement {
  connectedCallback() {
    this.firstChild.remove();
  }
}
customElements.define("c-parent", CParent);

class CChild extends HTMLElement {
  connectedCallback() {
    console.log("CChild connectedCallback: isConnected =", this.isConnected);
  }
}
customElements.define("c-child", CChild);

const parent = new CParent(),
      child = new CChild();
parent.append(child);

```

```
document.body.append(parent);

// Logs:
// CChild connectedCallback: isConnected = false
```

#### 4.13.3 Core concepts <sup>p75</sup>

A **custom element** is an element that is [custom](#). Informally, this means that its constructor and prototype are defined by the author, instead of by the user agent. This author-supplied constructor function is called the **custom element constructor**.

MDN

Two distinct types of [custom elements](#)<sup>p759</sup> can be defined:

1. An **autonomous custom element**, which is defined with no `extends` option. These types of custom elements have a local name equal to their [defined name](#)<sup>p761</sup>.
2. A **customized built-in element**, which is defined with an `extends` option. These types of custom elements have a local name equal to the value passed in their `extends` option, and their [defined name](#)<sup>p761</sup> is used as the value of the `is` attribute, which therefore must be a [valid custom element name](#)<sup>p760</sup>.

After a [custom element](#)<sup>p759</sup> is [created](#), changing the value of the `is`<sup>p759</sup> attribute does not change the element's behavior, as it is saved on the element as its [is value](#).

[Autonomous custom elements](#)<sup>p759</sup> have the following element definition:

##### Categories<sup>p146</sup>:

[Flow content](#)<sup>p149</sup>.

[Phrasing content](#)<sup>p150</sup>.

[Palpable content](#)<sup>p150</sup>.

For [form-associated custom elements](#)<sup>p760</sup>: [Listed](#)<sup>p513</sup>, [labelable](#)<sup>p514</sup>, [submittable](#)<sup>p514</sup>, and [resettable](#)<sup>p514</sup> [form-associated element](#)<sup>p513</sup>.

##### Contexts in which this element can be used<sup>p146</sup>:

Where [phrasing content](#)<sup>p150</sup> is expected.

##### Content model<sup>p146</sup>:

[Transparent](#)<sup>p151</sup>.

##### Content attributes<sup>p146</sup>:

[Global attributes](#)<sup>p154</sup>, except the `is`<sup>p759</sup> attribute

`form`<sup>p598</sup>, for [form-associated custom elements](#)<sup>p760</sup> — Associates the element with a [form](#)<sup>p514</sup> element

`disabled`<sup>p601</sup>, for [form-associated custom elements](#)<sup>p760</sup> — Whether the form control is disabled

`readonly`<sup>p760</sup>, for [form-associated custom elements](#)<sup>p760</sup> — Affects [willValidate](#)<sup>p625</sup>, plus any behavior added by the custom element author

`name`<sup>p599</sup>, for [form-associated custom elements](#)<sup>p760</sup> — Name of the element to use for [form submission](#)<sup>p628</sup> and in the

[form.elements](#)<sup>p516</sup> API

Any other attribute that has no namespace (see prose).

##### Accessibility considerations<sup>p146</sup>:

For [form-associated custom elements](#)<sup>p760</sup>: [for authors](#); [for implementers](#).

Otherwise: [for authors](#); [for implementers](#).

##### DOM interface<sup>p147</sup>:

Supplied by the element's author (inherits from [HTMLElement](#)<sup>p142</sup>)

An [autonomous custom element](#)<sup>p759</sup> does not have any special meaning: it [represents](#)<sup>p141</sup> its children. A [customized built-in element](#)<sup>p759</sup> inherits the semantics of the element that it extends.

Any namespace-less attribute that is relevant to the element's functioning, as determined by the element's author, may be specified on an [autonomous custom element](#)<sup>p759</sup>, so long as the attribute name is [XML-compatible](#)<sup>p45</sup> and contains no [ASCII upper alphas](#). The exception is the `is`<sup>p759</sup> attribute, which must not be specified on an [autonomous custom element](#)<sup>p759</sup> (and which will have no effect if it

is).

[Customized built-in elements](#)<sup>p759</sup> follow the normal requirements for attributes, based on the elements they extend. To add custom attribute-based behavior, use [data-\\*](#)<sup>p164</sup> attributes.

An [autonomous custom element](#)<sup>p759</sup> is called a **form-associated custom element** if the element is associated with a [custom element definition](#)<sup>p761</sup> whose [form-associated](#)<sup>p761</sup> field is set to true.

The [name](#)<sup>p599</sup> attribute represents the [form-associated custom element](#)<sup>p760</sup>'s name. The [disabled](#)<sup>p601</sup> attribute is used to make the [form-associated custom element](#)<sup>p760</sup> non-interactive and to prevent its [submission value](#)<sup>p773</sup> from being submitted. The [form](#)<sup>p598</sup> attribute is used to explicitly associate the [form-associated custom element](#)<sup>p760</sup> with its [form owner](#)<sup>p598</sup>.

The [readonly](#) attribute of [form-associated custom elements](#)<sup>p760</sup> specifies that the element is [barred from constraint validation](#)<sup>p622</sup>. User agents don't provide any other behavior for the attribute, but custom element authors should, where possible, use its presence to make their control non-editable in some appropriate fashion, similar to the behavior for the [readonly](#)<sup>p551</sup> attribute on built-in form controls.

**Constraint validation:** If the [readonly](#)<sup>p760</sup> attribute is specified on a [form-associated custom element](#)<sup>p760</sup>, the element is [barred from constraint validation](#)<sup>p622</sup>.

The [reset algorithm](#)<sup>p637</sup> for [form-associated custom elements](#)<sup>p760</sup> is to [enqueue a custom element callback reaction](#)<sup>p769</sup> with the element, callback name "formResetCallback", and an empty argument list.

A **valid custom element name** is a sequence of characters *name* that meets all of the following requirements:

- *name* must match the [PotentialCustomElementName](#)<sup>p760</sup> production:

*PotentialCustomElementName* ::=

[a-z] ([PCENChar](#)<sup>p760</sup>)\* '-' ([PCENChar](#)<sup>p760</sup>)\*

*PCENChar* ::=

"-" | "." | [0-9] | "\_" | [a-z] | #xB7 | [#xC0-#xD6] | [#xD8-#xF6] | [#xF8-#x37D] | [#x37F-#x1FFF] |  
[#x200C-#x200D] | [#x203F-#x2040] | [#x2070-#x218F] | [#x2C00-#x2FEF] | [#x3001-#xD7FF] |  
[#xF900-#xFDCF] | [#xFDF0-#xFFFD] | [#x10000-#xEFFFF]

This uses the [EBNF notation](#) from the XML specification. [\[XML\]](#)<sup>p1484</sup>

- *name* must not be any of the following:

- annotation-xml
- color-profile
- font-face
- font-face-src
- font-face-uri
- font-face-format
- font-face-name
- missing-glyph

#### Note

The list of names above is the summary of all hyphen-containing element names from the [applicable specifications](#)<sup>p73</sup>, namely SVG 2 and MathML. [\[SVG\]](#)<sup>p1482</sup> [\[MATHML\]](#)<sup>p1479</sup>

#### Note

These requirements ensure a number of goals for [valid custom element names](#)<sup>p760</sup>:

- They start with an [ASCII lower alpha](#), ensuring that the HTML parser will treat them as tags instead of as text.
- They do not contain any [ASCII upper alphas](#), ensuring that the user agent can always treat HTML elements ASCII-case-insensitively.
- They contain a hyphen, used for namespacing and to ensure forward compatibility (since no elements will be added to HTML, SVG, or MathML with hyphen-containing local names in the future).
- They can always be created with [createElement\(\)](#) and [createElementNS\(\)](#), which have restrictions that go beyond the

*parser's.*

*Apart from these restrictions, a large variety of names is allowed, to give maximum flexibility for use cases like `<math-α>` or `<emotion-😊>`.*

A **custom element definition** describes a [custom element](#)<sup>p759</sup> and consists of:

**A name**

A [valid custom element name](#)<sup>p760</sup>

**A local name**

A local name

**A constructor**

A Web IDL [CustomElementConstructor](#)<sup>p762</sup> callback function type value wrapping the [custom element constructor](#)<sup>p759</sup>

**A list of observed attributes**

A sequence<DOMString>

**A collection of lifecycle callbacks**

A map, whose keys are the strings "connectedCallback", "disconnectedCallback", "adoptedCallback", "attributeChangedCallback", "formAssociatedCallback", "formDisabledCallback", "formResetCallback", and "formStateRestoreCallback". The corresponding values are either a Web IDL [Function](#) callback function type value, or null. By default the value of each entry is null.

**A construction stack**

A list, initially empty, that is manipulated by the [upgrade an element](#)<sup>p765</sup> algorithm and the [HTML element constructors](#)<sup>p143</sup>. Each entry in the list will be either an element or an **already constructed marker**.

**A form-associated boolean**

If this is true, user agent treats elements associated to this [custom element definition](#)<sup>p761</sup> as [form-associated custom elements](#)<sup>p760</sup>.

**A disable internals boolean**

Controls [attachInternals\(\)](#)<sup>p770</sup>.

**A disable shadow boolean**

Controls [attachShadow\(\)](#).

To **look up a custom element definition**, given a *document*, *namespace*, *localName*, and *is*, perform the following steps. They will return either a [custom element definition](#)<sup>p761</sup> or null:

1. If *namespace* is not the [HTML namespace](#), return null.
2. If *document*'s [browsing context](#)<sup>p999</sup> is null, return null.
3. Let *registry* be *document*'s [relevant global object](#)<sup>p1083</sup>'s [CustomElementRegistry](#)<sup>p762</sup> object.
4. If there is a [custom element definition](#)<sup>p761</sup> in *registry* with [name](#)<sup>p761</sup> and [local name](#)<sup>p761</sup> both equal to *localName*, return that [custom element definition](#)<sup>p761</sup>.
5. If there is a [custom element definition](#)<sup>p761</sup> in *registry* with [name](#)<sup>p761</sup> equal to *is* and [local name](#)<sup>p761</sup> equal to *localName*, return that [custom element definition](#)<sup>p761</sup>.
6. Return null.

#### 4.13.4 The [CustomElementRegistry](#)<sup>p762</sup> interface <sup>§ p76</sup><sub>1</sub>

Each [Window](#)<sup>p922</sup> object is associated with a unique instance of a [CustomElementRegistry](#)<sup>p762</sup> object, allocated when the [Window](#)<sup>p922</sup> object is created.

**Note**

*Custom element registries are associated with [Window](#)<sup>p922</sup> objects, instead of [Document](#)<sup>p130</sup> objects, since each [custom element](#)*

[constructor](#)<sup>p759</sup> inherits from the [HTMLElement](#)<sup>p142</sup> interface, and there is exactly one [HTMLElement](#)<sup>p142</sup> interface per [Window](#)<sup>p922</sup> object.

MDN

The **customElements** attribute of the [Window](#)<sup>p922</sup> interface must return the [CustomElementRegistry](#)<sup>p762</sup> object for that [Window](#)<sup>p922</sup> object.

```
IDL [Exposed=Window]
interface CustomElementRegistry {
  [CEReactions] undefined define(DOMString name, CustomElementConstructor constructor, optional
  ElementDefinitionOptions options = {});
  (CustomElementConstructor or undefined) get(DOMString name);
  DOMString? getName(CustomElementConstructor constructor);
  Promise<CustomElementConstructor> whenDefined(DOMString name);
  [CEReactions] undefined upgrade(Node root);
};

callback CustomElementConstructor = HTMLElement ();

dictionary ElementDefinitionOptions {
  DOMString extends;
};
```

Every [CustomElementRegistry](#)<sup>p762</sup> has a set of [custom element definitions](#)<sup>p761</sup>, initially empty. In general, algorithms in this specification look up elements in the registry by any of [name](#)<sup>p761</sup>, [local name](#)<sup>p761</sup>, or [constructor](#)<sup>p761</sup>.

Every [CustomElementRegistry](#)<sup>p762</sup> also has an **element definition is running** flag which is used to prevent reentrant invocations of [element definition](#)<sup>p762</sup>. It is initially unset.

Every [CustomElementRegistry](#)<sup>p762</sup> also has a **when-defined promise map**, mapping [valid custom element names](#)<sup>p760</sup> to promises. It is used to implement the [whenDefined\(\)](#)<sup>p764</sup> method.

#### For web developers (non-normative)

[window.customElements](#)<sup>p762</sup>.[define](#)<sup>p762</sup>(*name*, *constructor*)

Defines a new [custom element](#)<sup>p759</sup>, mapping the given name to the given constructor as an [autonomous custom element](#)<sup>p759</sup>.

[window.customElements](#)<sup>p762</sup>.[define](#)<sup>p762</sup>(*name*, *constructor*, { *extends*: *baseLocalName* })

Defines a new [custom element](#)<sup>p759</sup>, mapping the given name to the given constructor as a [customized built-in element](#)<sup>p759</sup> for the [element type](#)<sup>p45</sup> identified by the supplied *baseLocalName*. A ["NotSupportedError" DOMException](#) will be thrown upon trying to extend a [custom element](#)<sup>p759</sup> or an unknown element.

[window.customElements](#)<sup>p762</sup>.[get](#)<sup>p764</sup>(*name*)

Retrieves the [custom element constructor](#)<sup>p759</sup> defined for the given [name](#)<sup>p761</sup>. Returns undefined if there is no [custom element definition](#)<sup>p761</sup> with the given [name](#)<sup>p761</sup>.

[window.customElements](#)<sup>p762</sup>.[getName](#)<sup>p764</sup>(*constructor*)

Retrieves the given name for a [custom element](#)<sup>p759</sup> defined for the given [constructor](#)<sup>p761</sup>. Returns null if there is no [custom element definition](#)<sup>p761</sup> with the given [constructor](#)<sup>p761</sup>.

[window.customElements](#)<sup>p762</sup>.[whenDefined](#)<sup>p764</sup>(*name*)

Returns a promise that will be fulfilled with the [custom element](#)<sup>p759</sup>'s constructor when a [custom element](#)<sup>p759</sup> becomes defined with the given name. (If such a [custom element](#)<sup>p759</sup> is already defined, the returned promise will be immediately fulfilled.) Returns a promise rejected with a ["SyntaxError" DOMException](#) if not given a [valid custom element name](#)<sup>p760</sup>.

[window.customElements](#)<sup>p762</sup>.[upgrade](#)<sup>p765</sup>(*root*)

Tries to [upgrade](#)<sup>p767</sup> all [shadow-including inclusive descendant](#) elements of *root*, even if they are not [connected](#).

**Element definition** is a process of adding a [custom element definition](#)<sup>p761</sup> to the [CustomElementRegistry](#)<sup>p762</sup>. This is accomplished by the [define\(\)](#)<sup>p762</sup> method. When invoked, the [define\(name, constructor, options\)](#) method must run these steps:

1. If [IsConstructor\(constructor\)](#) is false, then throw a [TypeError](#).

2. If *name* is not a [valid custom element name](#)<sup>p760</sup>, then throw a ["SyntaxError" DOMException](#).
3. If this [CustomElementRegistry](#)<sup>p762</sup> contains an entry with [name](#)<sup>p761</sup> *name*, then throw a ["NotSupportedError" DOMException](#).
4. If this [CustomElementRegistry](#)<sup>p762</sup> contains an entry with [constructor](#)<sup>p761</sup> *constructor*, then throw a ["NotSupportedError" DOMException](#).
5. Let *localName* be *name*.
6. Let *extends* be the value of the *extends* member of *options*, or null if no such member exists.
7. If *extends* is not null, then:
  1. If *extends* is a [valid custom element name](#)<sup>p760</sup>, then throw a ["NotSupportedError" DOMException](#).
  2. If the [element interface](#) for *extends* and the [HTML namespace](#) is [HTMLUnknownElement](#)<sup>p142</sup> (e.g., if *extends* does not indicate an element definition in this specification), then throw a ["NotSupportedError" DOMException](#).
  3. Set *localName* to *extends*.
8. If this [CustomElementRegistry](#)<sup>p762</sup>'s [element definition is running](#)<sup>p762</sup> flag is set, then throw a ["NotSupportedError" DOMException](#).
9. Set this [CustomElementRegistry](#)<sup>p762</sup>'s [element definition is running](#)<sup>p762</sup> flag.
10. Let *formAssociated* be false.
11. Let *disableInternals* be false.
12. Let *disableShadow* be false.
13. Let *observedAttributes* be an empty [sequence](#)<DOMString>.
14. Run the following substeps while catching any exceptions:
  1. Let *prototype* be ? [Get](#)(*constructor*, "prototype").
  2. If *prototype* is not an Object, then throw a [TypeError](#) exception.
  3. Let *lifecycleCallbacks* be a map with the keys "connectedCallback", "disconnectedCallback", "adoptedCallback", and "attributeChangedCallback", each of which belongs to an entry whose value is null.
  4. For each of the keys *callbackName* in *lifecycleCallbacks*, in the order listed in the previous step:
    1. Let *callbackValue* be ? [Get](#)(*prototype*, *callbackName*).
    2. If *callbackValue* is not undefined, then set the value of the entry in *lifecycleCallbacks* with key *callbackName* to the result of [converting](#) *callbackValue* to the Web IDL [Function](#) callback type. Rethrow any exceptions from the conversion.
  5. If the value of the entry in *lifecycleCallbacks* with key "attributeChangedCallback" is not null, then:
    1. Let *observedAttributesIterable* be ? [Get](#)(*constructor*, "observedAttributes").
    2. If *observedAttributesIterable* is not undefined, then set *observedAttributes* to the result of [converting](#) *observedAttributesIterable* to a [sequence](#)<DOMString>. Rethrow any exceptions from the conversion.
  6. Let *disabledFeatures* be an empty [sequence](#)<DOMString>.
  7. Let *disabledFeaturesIterable* be ? [Get](#)(*constructor*, "disabledFeatures").
  8. If *disabledFeaturesIterable* is not undefined, then set *disabledFeatures* to the result of [converting](#) *disabledFeaturesIterable* to a [sequence](#)<DOMString>. Rethrow any exceptions from the conversion.
  9. Set *disableInternals* to true if *disabledFeatures* [contains](#) "internals".
  10. Set *disableShadow* to true if *disabledFeatures* [contains](#) "shadow".
  11. Let *formAssociatedValue* be ? [Get](#)(*constructor*, "formAssociated").
  12. Set *formAssociated* to the result of [converting](#) *formAssociatedValue* to a boolean. Rethrow any exceptions from the

conversion.

13. If *formAssociated* is true, for each of "formAssociatedCallback", "formResetCallback", "formDisabledCallback", and "formStateRestoreCallback" *callbackName*:
  1. Let *callbackValue* be ? [Get\(prototype, callbackName\)](#).
  2. If *callbackValue* is not undefined, then set the value of the entry in *lifecycleCallbacks* with key *callbackName* to the result of [converting](#) *callbackValue* to the Web IDL [Function](#) callback type. Rethrow any exceptions from the conversion.

Then, perform the following substep, regardless of whether the above steps threw an exception or not:

1. Unset this [CustomElementRegistry](#)<sup>p762</sup>'s [element definition is running](#)<sup>p762</sup> flag.

Finally, if the first set of substeps threw an exception, then rethrow that exception (thus terminating this algorithm). Otherwise, continue onward.

15. Let *definition* be a new [custom element definition](#)<sup>p761</sup> with [name](#)<sup>p761</sup> *name*, [local name](#)<sup>p761</sup> *localName*, [constructor](#)<sup>p761</sup> *constructor*, [observed attributes](#)<sup>p761</sup> *observedAttributes*, [lifecycle callbacks](#)<sup>p761</sup> *lifecycleCallbacks*, [form-associated](#)<sup>p761</sup> *formAssociated*, [disable internals](#)<sup>p761</sup> *disableInternals*, and [disable shadow](#)<sup>p761</sup> *disableShadow*.
16. Add *definition* to this [CustomElementRegistry](#)<sup>p762</sup>.
17. Let *document* be this [CustomElementRegistry](#)<sup>p762</sup>'s [relevant global object](#)<sup>p1083</sup>'s [associated Document](#)<sup>p923</sup>.
18. Let *upgrade candidates* be all elements that are [shadow-including descendants](#) of *document*, whose namespace is the [HTML namespace](#) and whose local name is *localName*, in [shadow-including tree order](#). Additionally, if *extends* is non-null, only include elements whose [is value](#) is equal to *name*.
19. For each element *element* in *upgrade candidates*, [enqueue a custom element upgrade reaction](#)<sup>p769</sup> given *element* and *definition*.
20. If this [CustomElementRegistry](#)<sup>p762</sup>'s [when-defined promise map](#)<sup>p762</sup> contains an entry with key *name*:
  1. Let *promise* be the value of that entry.
  2. Resolve *promise* with *constructor*.
  3. Delete the entry with key *name* from this [CustomElementRegistry](#)<sup>p762</sup>'s [when-defined promise map](#)<sup>p762</sup>.

When invoked, the [get\(name\)](#) method must run these steps:

1. If this [CustomElementRegistry](#)<sup>p762</sup> contains an entry with [name](#)<sup>p761</sup> *name*, then return that entry's [constructor](#)<sup>p761</sup>.
2. Otherwise, return undefined.

The [getName\(constructor\)](#) method steps are:

MDN

1. If this [CustomElementRegistry](#)<sup>p762</sup> contains an entry with [constructor](#)<sup>p761</sup> *constructor*, then return that entry's [name](#)<sup>p761</sup>.
2. Return null.

When invoked, the [whenDefined\(name\)](#) method must run these steps:

1. If *name* is not a [valid custom element name](#)<sup>p760</sup>, then return [a promise rejected with a "SyntaxError" DOMException](#).
2. If this [CustomElementRegistry](#)<sup>p762</sup> contains an entry with [name](#)<sup>p761</sup> *name*, then return [a promise resolved with](#) that entry's [constructor](#)<sup>p761</sup>.
3. Let *map* be this [CustomElementRegistry](#)<sup>p762</sup>'s [when-defined promise map](#)<sup>p762</sup>.
4. If *map* does not contain an entry with key *name*, create an entry in *map* with key *name* and whose value is a new promise.
5. Let *promise* be the value of the entry in *map* with key *name*.
6. Return *promise*.

## Example

The `whenDefined()`<sup>p764</sup> method can be used to avoid performing an action until all appropriate [custom elements](#)<sup>p759</sup> are [defined](#). In this example, we combine it with the `:defined`<sup>p783</sup> pseudo-class to hide a dynamically-loaded article's contents until we're sure that all of the [autonomous custom elements](#)<sup>p759</sup> it uses are defined.

```
articleContainer.hidden = true;

fetch(articleURL)
  .then(response => response.text())
  .then(text => {
    articleContainer.innerHTML = text;

    return Promise.all(
      [...articleContainer.querySelectorAll(":not(:defined)")]
        .map(el => customElements.whenDefined(el.localName))
    );
  })
  .then(() => {
    articleContainer.hidden = false;
  });
```

When invoked, the `upgrade(root)` method must run these steps:

1. Let *candidates* be a [list](#) of all of *root*'s [shadow-including inclusive descendant](#) elements, in [shadow-including tree order](#).
2. [For each](#) *candidate* of *candidates*, [try to upgrade](#)<sup>p767</sup> *candidate*.

#### Example

The `upgrade()`<sup>p765</sup> method allows upgrading of elements at will. Normally elements are automatically upgraded when they become [connected](#), but this method can be used if you need to upgrade before you're ready to connect the element.

```
const el = document.createElement("spider-man");

class SpiderMan extends HTMLElement {}
customElements.define("spider-man", SpiderMan);

console.assert(!(el instanceof SpiderMan)); // not yet upgraded

customElements.upgrade(el);
console.assert(el instanceof SpiderMan);    // upgraded!
```

### 4.13.5 Upgrades <sup>p76</sup><sub>5</sub>

To **upgrade an element**, given as input a [custom element definition](#)<sup>p761</sup> *definition* and an element *element*, run the following steps:

1. If *element*'s [custom element state](#) is not "undefined" or "uncustomized", then return.

#### Example

One scenario where this can occur due to reentrant invocation of this algorithm, as in the following example:

```
<!DOCTYPE html>
<x-foo id="a"></x-foo>
<x-foo id="b"></x-foo>

<script>
// Defining enqueues upgrade reactions for both "a" and "b"
customElements.define("x-foo", class extends HTMLElement {
  constructor() {
```

```

    super();

    const b = document.querySelector("#b");
    b.remove();

    // While this constructor is running for "a", "b" is still
    // undefined, and so inserting it into the document will enqueue a
    // second upgrade reaction for "b" in addition to the one enqueued
    // by defining x-foo.
    document.body.appendChild(b);
  }
})
</script>

```

This step will thus bail out the algorithm early when [upgrade an element](#)<sup>p765</sup> is invoked with "b" a second time.

2. Set *element*'s [custom element definition](#) to *definition*.
3. Set *element*'s [custom element state](#) to "failed".

#### Note

*It will be set to "custom" [after the upgrade succeeds](#)<sup>p767</sup>. For now, we set it to "failed" so that any reentrant invocations will hit [the above early-exit step](#)<sup>p765</sup>.*

4. For each *attribute* in *element*'s [attribute list](#), in order, [enqueue a custom element callback reaction](#)<sup>p769</sup> with *element*, callback name "attributeChangedCallback", and an argument list containing *attribute*'s local name, null, *attribute*'s value, and *attribute*'s namespace.
5. If *element* is [connected](#), then [enqueue a custom element callback reaction](#)<sup>p769</sup> with *element*, callback name "connectedCallback", and an empty argument list.
6. Add *element* to the end of *definition*'s [construction stack](#)<sup>p761</sup>.
7. Let *C* be *definition*'s [constructor](#)<sup>p761</sup>.
8. Run the following substeps while catching any exceptions:
  1. If *definition*'s [disable shadow](#)<sup>p761</sup> is true and *element*'s [shadow root](#) is non-null, then throw a ["NotSupportedError" DOMException](#).

#### Note

*This is needed as [attachShadow\(\)](#) does not use [look up a custom element definition](#)<sup>p761</sup> while [attachInternals\(\)](#)<sup>p770</sup> does.*

2. Set *element*'s [custom element state](#) to "precustomized".
3. Let *constructResult* be the result of [constructing](#) *C*, with no arguments.

#### Note

*If *C* [non-conformantly](#)<sup>p758</sup> uses an API decorated with the [\[CEReactions\]](#)<sup>p769</sup> extended attribute, then the reactions enqueued at the beginning of this algorithm will execute during this step, before *C* finishes and control returns to this algorithm. Otherwise, they will execute after *C* and the rest of the upgrade process finishes.*

4. If [SameValue](#)(*constructResult*, *element*) is false, then throw a [TypeError](#).

#### Note

*This can occur if *C* constructs another instance of the same custom element before calling `super()`, or if *C* uses JavaScript's return-override feature to return an arbitrary [HTMLElement](#)<sup>p142</sup> object from the constructor.*

Then, perform the following substep, regardless of whether the above steps threw an exception or not:

1. Remove the last entry from the end of *definition*'s [construction stack](#)<sup>p761</sup>.

**Note**

Assuming *C* calls `super()` (as it will if it is [conformant](#)<sup>p758</sup>), and that the call succeeds, this will be the [already constructed marker](#)<sup>p761</sup> that replaced the element we pushed at the beginning of this algorithm. (The [HTML element constructor](#)<sup>p143</sup> carries out this replacement.)

If *C* does not call `super()` (i.e. it is not [conformant](#)<sup>p758</sup>), or if any step in the [HTML element constructor](#)<sup>p143</sup> throws, then this entry will still be `element`.

Finally, if the above steps threw an exception, then:

1. Set *element*'s [custom element definition](#) to null.
2. Empty *element*'s [custom element reaction queue](#)<sup>p768</sup>.
3. Rethrow the exception (thus terminating this algorithm).

**Note**

If the above steps threw an exception, then *element*'s [custom element state](#) will remain "failed" or "precustomized".

9. If *element* is a [form-associated custom element](#)<sup>p760</sup>, then:
  1. [Reset the form owner](#)<sup>p598</sup> of *element*. If *element* is associated with a [form](#)<sup>p514</sup> element, then [enqueue a custom element callback reaction](#)<sup>p769</sup> with *element*, callback name "formAssociatedCallback", and « the associated [form](#)<sup>p514</sup> ».
  2. If *element* is [disabled](#)<sup>p601</sup>, then [enqueue a custom element callback reaction](#)<sup>p769</sup> with *element*, callback name "formDisabledCallback" and « true ».
10. Set *element*'s [custom element state](#) to "custom".

To **try to upgrade an element**, given as input an element *element*, run the following steps:

1. Let *definition* be the result of [looking up a custom element definition](#)<sup>p761</sup> given *element*'s [node document](#), *element*'s namespace, *element*'s local name, and *element*'s [is value](#).
2. If *definition* is not null, then [enqueue a custom element upgrade reaction](#)<sup>p769</sup> given *element* and *definition*.

#### 4.13.6 Custom element reactions §<sup>p76</sup> 7

A [custom element](#)<sup>p759</sup> possesses the ability to respond to certain occurrences by running author code:

- When [upgraded](#)<sup>p765</sup>, its [constructor](#)<sup>p759</sup> is run, with no arguments.
- When it [becomes connected](#)<sup>p46</sup>, its `connectedCallback` is called, with no arguments.
- When it [becomes disconnected](#)<sup>p46</sup>, its `disconnectedCallback` is called, with no arguments.
- When it is [adopted](#) into a new document, its `adoptedCallback` is called, given the old document and new document as arguments.
- When any of its attributes are [changed](#), [appended](#), [removed](#), or [replaced](#), its `attributeChangedCallback` is called, given the attribute's local name, old value, new value, and namespace as arguments. (An attribute's old or new value is considered to be null when the attribute is added or removed, respectively.)
- When the user agent [resets the form owner](#)<sup>p598</sup> of a [form-associated custom element](#)<sup>p760</sup> and doing so changes the form owner, its `formAssociatedCallback` is called, given the new form owner (or null if no owner) as an argument.
- When the form owner of a [form-associated custom element](#)<sup>p760</sup> is [reset](#)<sup>p637</sup>, its `formResetCallback` is called.
- When the [disabled](#)<sup>p601</sup> state of a [form-associated custom element](#)<sup>p760</sup> is changed, its `formDisabledCallback` is called, given the new state as an argument.
- When user agent updates a [form-associated custom element](#)<sup>p760</sup>'s value on behalf of a user or [as part of navigation](#)<sup>p1055</sup>, its `formStateRestoreCallback` is called, given the new state and a string indicating a reason, "autocomplete" or "restore", as arguments.

We call these reactions collectively **custom element reactions**.

The way in which [custom element reactions](#)<sup>p768</sup> are invoked is done with special care, to avoid running author code during the middle of delicate operations. Effectively, they are delayed until "just before returning to user script". This means that for most purposes they appear to execute synchronously, but in the case of complicated composite operations (like [cloning](#), or [range](#) manipulation), they will instead be delayed until after all the relevant user agent processing steps have completed, and then run together as a batch.

Additionally, the precise ordering of these reactions is managed via a somewhat-complicated stack-of-queues system, described below. The intention behind this system is to guarantee that [custom element reactions](#)<sup>p768</sup> always are invoked in the same order as their triggering actions, at least within the local context of a single [custom element](#)<sup>p759</sup>. (Because [custom element reaction](#)<sup>p768</sup> code can perform its own mutations, it is not possible to give a global ordering guarantee across multiple elements.)

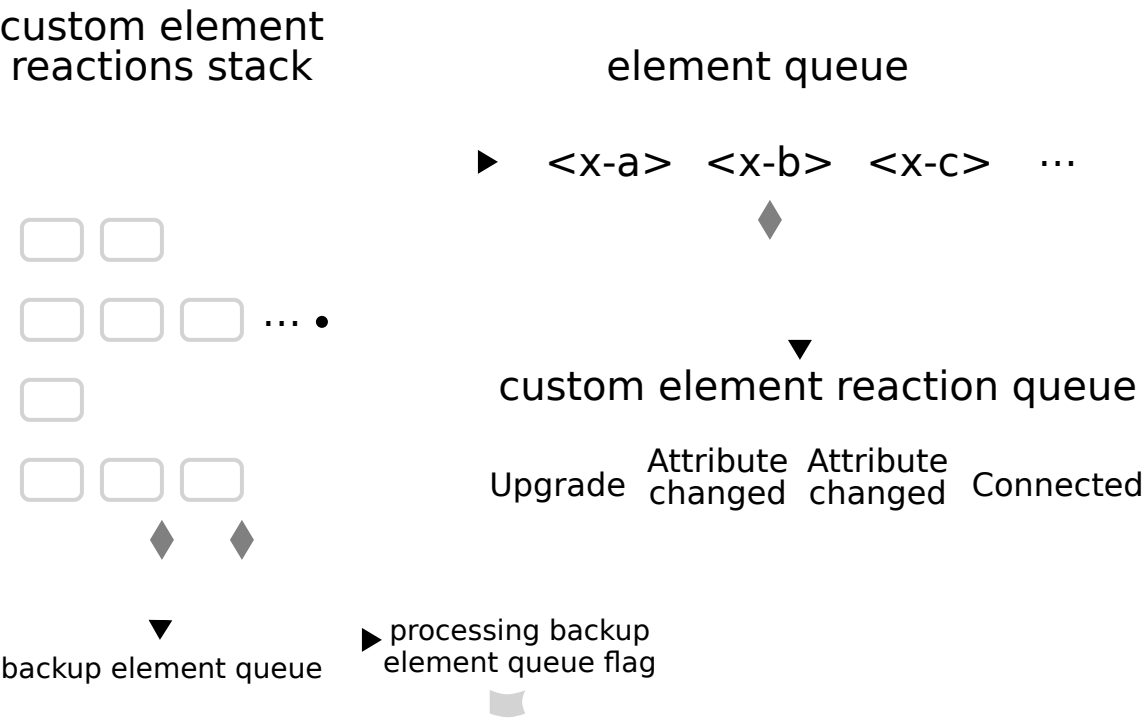

Each [similar-origin window agent](#)<sup>p1072</sup> has a **custom element reactions stack**, which is initially empty. A [similar-origin window agent](#)<sup>p1072</sup>'s **current element queue** is the [element queue](#)<sup>p768</sup> at the top of its [custom element reactions stack](#)<sup>p768</sup>. Each item in the stack is an **element queue**, which is initially empty as well. Each item in an [element queue](#)<sup>p768</sup> is an element. (The elements are not necessarily [custom](#) yet, since this queue is used for [upgrades](#)<sup>p765</sup> as well.)

Each [custom element reactions stack](#)<sup>p768</sup> has an associated **backup element queue**, which is an initially-empty [element queue](#)<sup>p768</sup>. Elements are pushed onto the [backup element queue](#)<sup>p768</sup> during operations that affect the DOM without going through an API decorated with [\[CEReactions\]](#)<sup>p769</sup>, or through the parser's [create an element for the token](#)<sup>p1320</sup> algorithm. An example of this is a user-initiated editing operation which modifies the descendants or attributes of an [editable](#) element. To prevent reentrancy when processing the [backup element queue](#)<sup>p768</sup>, each [custom element reactions stack](#)<sup>p768</sup> also has a **processing the backup element queue** flag, initially unset.

All elements have an associated **custom element reaction queue**, initially empty. Each item in the [custom element reaction queue](#)<sup>p768</sup> is of one of two types:

- An **upgrade reaction**, which will [upgrade](#)<sup>p765</sup> the custom element and contains a [custom element definition](#)<sup>p761</sup>; or
- A **callback reaction**, which will call a lifecycle callback, and contains a callback function as well as a list of arguments.

This is all summarized in the following schematic diagram:

To **enqueue an element on the appropriate element queue**, given an element *element*, run the following steps:

1. Let *reactionsStack* be *element*'s [relevant agent](#)<sup>p1073</sup>'s [custom element reactions stack](#)<sup>p768</sup>.

2. If *reactionsStack* is empty, then:

1. Add *element* to *reactionsStack*'s [backup element queue](#)<sup>p768</sup>.
2. If *reactionsStack*'s [processing the backup element queue](#)<sup>p768</sup> flag is set, then return.
3. Set *reactionsStack*'s [processing the backup element queue](#)<sup>p768</sup> flag.
4. [Queue a microtask](#)<sup>p1125</sup> to perform the following steps:
  1. [Invoke custom element reactions](#)<sup>p769</sup> in *reactionsStack*'s [backup element queue](#)<sup>p768</sup>.
  2. Unset *reactionsStack*'s [processing the backup element queue](#)<sup>p768</sup> flag.
3. Otherwise, add *element* to *element*'s [relevant agent](#)<sup>p1073</sup>'s [current element queue](#)<sup>p768</sup>.

To **enqueue a custom element callback reaction**, given a [custom element](#)<sup>p759</sup> *element*, a callback name *callbackName*, and a list of arguments *args*, run the following steps:

1. Let *definition* be *element*'s [custom element definition](#).
2. Let *callback* be the value of the entry in *definition*'s [lifecycle callbacks](#)<sup>p761</sup> with key *callbackName*.
3. If *callback* is null, then return.
4. If *callbackName* is "attributeChangedCallback", then:
  1. Let *attributeName* be the first element of *args*.
  2. If *definition*'s [observed attributes](#)<sup>p761</sup> does not contain *attributeName*, then return.
5. Add a new [callback reaction](#)<sup>p768</sup> to *element*'s [custom element reaction queue](#)<sup>p768</sup>, with callback function *callback* and arguments *args*.
6. [Enqueue an element on the appropriate element queue](#)<sup>p768</sup> given *element*.

To **enqueue a custom element upgrade reaction**, given an element *element* and [custom element definition](#)<sup>p761</sup> *definition*, run the following steps:

1. Add a new [upgrade reaction](#)<sup>p768</sup> to *element*'s [custom element reaction queue](#)<sup>p768</sup>, with [custom element definition](#)<sup>p761</sup> *definition*.
2. [Enqueue an element on the appropriate element queue](#)<sup>p768</sup> given *element*.

To **invoke custom element reactions** in an [element queue](#)<sup>p768</sup> *queue*, run the following steps:

1. While *queue* is not [empty](#):
  1. Let *element* be the result of [dequeuing](#) from *queue*.
  2. Let *reactions* be *element*'s [custom element reaction queue](#)<sup>p768</sup>.
  3. Repeat until *reactions* is empty:
    1. Remove the first element of *reactions*, and let *reaction* be that element. Switch on *reaction*'s type:
      - ↪ [upgrade reaction](#)<sup>p768</sup>  
[Upgrade](#)<sup>p765</sup> *element* using *reaction*'s [custom element definition](#)<sup>p761</sup>.
      - If this throws an exception, catch it, and [report](#)<sup>p1098</sup> it for *reaction*'s [custom element definition](#)<sup>p761</sup>'s [constructor](#)<sup>p761</sup>'s corresponding JavaScript object's [associated realm](#)'s [global object](#)<sup>p1077</sup>.
      - ↪ [callback reaction](#)<sup>p768</sup>  
[Invoke](#) *reaction*'s callback function with *reaction*'s arguments and "report", and [callback this value](#) set to *element*.

To ensure [custom element reactions](#)<sup>p768</sup> are triggered appropriately, we introduce the **[CEReactions]** IDL [extended attribute](#). It indicates that the relevant algorithm is to be supplemented with additional steps in order to appropriately track and invoke [custom](#)

[element reactions](#)<sup>p768</sup>.

The [\[CEReactions\]](#)<sup>p769</sup> extended attribute must take no arguments, and must not appear on anything other than an operation, attribute, setter, or deleter. Additionally, it must not appear on readonly attributes.

Operations, attributes, setters, or deleters annotated with the [\[CEReactions\]](#)<sup>p769</sup> extended attribute must run the following steps in place of the ones specified in their description:

1. [Push](#) a new [element queue](#)<sup>p768</sup> onto this object's [relevant agent](#)<sup>p1073</sup>'s [custom element reactions stack](#)<sup>p768</sup>.
2. Run the originally-specified steps for this construct, catching any exceptions. If the steps return a value, let *value* be the returned value. If they throw an exception, let *exception* be the thrown exception.
3. Let *queue* be the result of [popping](#) from this object's [relevant agent](#)<sup>p1073</sup>'s [custom element reactions stack](#)<sup>p768</sup>.
4. [Invoke custom element reactions](#)<sup>p769</sup> in *queue*.
5. If an exception *exception* was thrown by the original steps, rethrow *exception*.
6. If a value *value* was returned from the original steps, return *value*.

#### Note

*The intent behind this extended attribute is somewhat subtle. One way of accomplishing its goals would be to say that every operation, attribute, setter, and deleter on the platform must have these steps inserted, and to allow implementers to optimize away unnecessary cases (where no DOM mutation is possible that could cause [custom element reactions](#)<sup>p768</sup> to occur).*

*However, in practice this imprecision could lead to non-interoperable implementations of [custom element reactions](#)<sup>p768</sup>, as some implementations might forget to invoke these steps in some cases. Instead, we settled on the approach of explicitly annotating all relevant IDL constructs, as a way of ensuring interoperable behavior and helping implementations easily pinpoint all cases where these steps are necessary.*

Any nonstandard APIs introduced by the user agent that could modify the DOM in such a way as to cause [enqueueing a custom element callback reaction](#)<sup>p769</sup> or [enqueueing a custom element upgrade reaction](#)<sup>p769</sup>, for example by modifying any attributes or child elements, must also be decorated with the [\[CEReactions\]](#)<sup>p769</sup> attribute.

#### Note

*As of the time of this writing, the following nonstandard or not-yet-standardized APIs are known to fall into this category:*

- [HTMLInputElement](#)<sup>p522</sup>'s [webkitdirectory](#) and incremental IDL attributes
- [HTMLLinkElement](#)<sup>p178</sup>'s [scope](#) IDL attribute

### 4.13.7 Element internals §<sup>p77</sup><sub>0</sub>

Certain capabilities are meant to be available to a custom element author, but not to a custom element consumer. These are provided by the [element.attachInternals\(\)](#)<sup>p770</sup> method, which returns an instance of [ElementInternals](#)<sup>p771</sup>. The properties and methods of [ElementInternals](#)<sup>p771</sup> allow control over internal features which the user agent provides to all elements.

For web developers (non-normative)

#### [element.attachInternals\(\)](#)<sup>p770</sup>

Returns an [ElementInternals](#)<sup>p771</sup> object targeting the [custom element](#)<sup>p759</sup> *element*. Throws an exception if *element* is not a [custom element](#)<sup>p759</sup>, if the "internals" feature was disabled as part of the element definition, or if it is called twice on the same element.

Each [HTMLElement](#)<sup>p142</sup> has an **attached internals** (null or an [ElementInternals](#)<sup>p771</sup> object), initially null.

The [attachInternals\(\)](#) method steps are:

1. If *this*'s *is value* is not null, then throw a ["NotSupportedError"](#) [DOMException](#).

- Let *definition* be the result of [looking up a custom element definition](#)<sup>p761</sup> given *this*'s [node document](#), its namespace, its local name, and null as the *is value*.
- If *definition* is null, then throw an ["NotSupportedError" DOMException](#).
- If *definition*'s [disable internals](#)<sup>p761</sup> is true, then throw a ["NotSupportedError" DOMException](#).
- If *this*'s [attached internals](#)<sup>p770</sup> is non-null, then throw an ["NotSupportedError" DOMException](#).
- If *this*'s [custom element state](#) is not "precustomized" or "custom", then throw a ["NotSupportedError" DOMException](#).
- Set *this*'s [attached internals](#)<sup>p770</sup> to a new [ElementInternals](#)<sup>p771</sup> instance whose [target element](#)<sup>p772</sup> is *this*.
- Return *this*'s [attached internals](#)<sup>p770</sup>.

#### 4.13.7.1 The [ElementInternals](#)<sup>p771</sup> interface §<sup>p77</sup><sub>1</sub>

The IDL for the [ElementInternals](#)<sup>p771</sup> interface is as follows, with the various operations and attributes defined in the following sections:

```
IDL [Exposed=Window]
interface ElementInternals {
  // Shadow root access
  readonly attribute ShadowRoot? shadowRoot;

  // Form-associated custom elements
  undefined setFormValue((File or USVString or FormData)? value,
                        optional (File or USVString or FormData)? state);

  readonly attribute HTMLFormElement? form;

  undefined setValidity(optional ValidityStateFlags flags = {},
                        optional DOMString message,
                        optional HTMLElement anchor);
  readonly attribute boolean willValidate;
  readonly attribute ValidityState validity;
  readonly attribute DOMString validationMessage;
  boolean checkValidity();
  boolean reportValidity();

  readonly attribute NodeList labels;

  // Custom state pseudo-class
  [SameObject] readonly attribute CustomStateSet states;
};

// Accessibility semantics
ElementInternals includes ARIAMixin;

dictionary ValidityStateFlags {
  boolean valueMissing = false;
  boolean typeMismatch = false;
  boolean patternMismatch = false;
  boolean tooLong = false;
  boolean tooShort = false;
  boolean rangeUnderflow = false;
  boolean rangeOverflow = false;
  boolean stepMismatch = false;
  boolean badInput = false;
  boolean customError = false;
};
```

Each [ElementInternals](#)<sup>p771</sup> has a **target element**, which is a [custom element](#)<sup>p759</sup>.

#### 4.13.7.2 Shadow root access <sup>p772</sup>

For web developers (non-normative)

**[internals.shadowRoot](#)**<sup>p772</sup>

Returns the [ShadowRoot](#) for *internals*'s [target element](#)<sup>p772</sup>, if the [target element](#)<sup>p772</sup> is a [shadow host](#), or null otherwise.

The **shadowRoot** getter steps are:

1. Let *target* be *this*'s [target element](#)<sup>p772</sup>.
2. If *target* is not a [shadow host](#), then return null.
3. Let *shadow* be *target*'s [shadow root](#).
4. If *shadow*'s [available to element internals](#) is false, then return null.
5. Return *shadow*.

#### 4.13.7.3 Form-associated custom elements <sup>p772</sup>

For web developers (non-normative)

**[internals.setFormValue](#)**<sup>p773</sup>(*value*)

Sets both the [state](#)<sup>p773</sup> and [submission value](#)<sup>p773</sup> of *internals*'s [target element](#)<sup>p772</sup> to *value*.

If *value* is null, the element won't participate in form submission.

**[internals.setFormValue](#)**<sup>p773</sup>(*value*, *state*)

Sets the [submission value](#)<sup>p773</sup> of *internals*'s [target element](#)<sup>p772</sup> to *value*, and its [state](#)<sup>p773</sup> to *state*.

If *value* is null, the element won't participate in form submission.

**[internals.form](#)**<sup>p599</sup>

Returns the [form owner](#)<sup>p598</sup> of *internals*'s [target element](#)<sup>p772</sup>.

**[internals.setValidity](#)**<sup>p773</sup>(*flags*, *message* [, *anchor* ])

Marks *internals*'s [target element](#)<sup>p772</sup> as suffering from the constraints indicated by the *flags* argument, and sets the element's validation message to *message*. If *anchor* is specified, the user agent might use it to indicate problems with the constraints of *internals*'s [target element](#)<sup>p772</sup> when the [form owner](#)<sup>p598</sup> is validated interactively or [reportValidity\(\)](#)<sup>p627</sup> is called.

**[internals.setValidity](#)**<sup>p773</sup>({})

Marks *internals*'s [target element](#)<sup>p772</sup> as [satisfying its constraints](#)<sup>p623</sup>.

**[internals.willValidate](#)**<sup>p625</sup>

Returns true if *internals*'s [target element](#)<sup>p772</sup> will be validated when the form is submitted; false otherwise.

**[internals.validity](#)**<sup>p626</sup>

Returns the [ValidityState](#)<sup>p626</sup> object for *internals*'s [target element](#)<sup>p772</sup>.

**[internals.validationMessage](#)**<sup>p774</sup>

Returns the error message that would be shown to the user if *internals*'s [target element](#)<sup>p772</sup> was to be checked for validity.

***valid* = [internals.checkValidity\(\)](#)**<sup>p627</sup>

Returns true if *internals*'s [target element](#)<sup>p772</sup> has no validity problems; false otherwise. Fires an [invalid](#)<sup>p1471</sup> event at the element in the latter case.

***valid* = [internals.reportValidity\(\)](#)**<sup>p627</sup>

Returns true if *internals*'s [target element](#)<sup>p772</sup> has no validity problems; otherwise, returns false, fires an [invalid](#)<sup>p1471</sup> event at the element, and (if the event isn't canceled) reports the problem to the user.

## `internals.labels`<sup>p520</sup>

Returns a [NodeList](#) of all the [label](#)<sup>p518</sup> elements that *internals*'s [target element](#)<sup>p772</sup> is associated with.

Each [form-associated custom element](#)<sup>p760</sup> has **submission value**. It is used to provide one or more [entries](#)<sup>p632</sup> on form submission. The initial value of [submission value](#)<sup>p773</sup> is null, and [submission value](#)<sup>p773</sup> can be null, a string, a [File](#), or a [list](#) of [entries](#)<sup>p632</sup>.

Each [form-associated custom element](#)<sup>p760</sup> has **state**. It is information with which the user agent can restore a user's input for the element. The initial value of [state](#)<sup>p773</sup> is null, and [state](#)<sup>p773</sup> can be null, a string, a [File](#), or a [list](#) of [entries](#)<sup>p632</sup>.

The [setFormValue\(\)](#)<sup>p773</sup> method is used by the custom element author to set the element's [submission value](#)<sup>p773</sup> and [state](#)<sup>p773</sup>, thus communicating these to the user agent.

When the user agent believes it is a good idea to restore a [form-associated custom element](#)<sup>p760</sup>'s [state](#)<sup>p773</sup>, for example [after navigation](#)<sup>p1055</sup> or restarting the user agent, they may [enqueue a custom element callback reaction](#)<sup>p769</sup> with that element, callback name "formStateRestoreCallback", an argument list containing the state to be restored, and "restore".

If the user agent has a form-filling assist feature, then when the feature is invoked, it may [enqueue a custom element callback reaction](#)<sup>p769</sup> with a [form-associated custom element](#)<sup>p760</sup>, callback name "formStateRestoreCallback", an argument list containing the state value determined by history of state value and some heuristics, and "autocomplete".

In general, the [state](#)<sup>p773</sup> is information specified by a user, and the [submission value](#)<sup>p773</sup> is a value after canonicalization or sanitization, suitable for submission to the server. The following examples makes this concrete:

### Example

Suppose that we have a [form-associated custom element](#)<sup>p760</sup> which asks a user to specify a date. The user specifies "3/15/2019", but the control wishes to submit "2019-03-15" to the server. "3/15/2019" would be a [state](#)<sup>p773</sup> of the element, and "2019-03-15" would be a [submission value](#)<sup>p773</sup>.

### Example

Suppose you develop a custom element emulating a the behavior of the existing [checkbox](#)<sup>p542</sup> [input](#)<sup>p520</sup> type. Its [submission value](#)<sup>p773</sup> would be the value of its value content attribute, or the string "on". Its [state](#)<sup>p773</sup> would be one of "checked", "unchecked", "checked/indeterminate", or "unchecked/indeterminate".

The [setFormValue\(value, state\)](#) method steps are:

1. Let *element* be [this](#)'s [target element](#)<sup>p772</sup>.
2. If *element* is not a [form-associated custom element](#)<sup>p760</sup>, then throw a ["NotSupportedError"](#) [DOMException](#).
3. Set [target element](#)<sup>p772</sup>'s [submission value](#)<sup>p773</sup> to *value* if *value* is not a [FormData](#) object, or to a [clone](#) of *value*'s [entry list](#) otherwise.
4. If the *state* argument of the function is omitted, set *element*'s [state](#)<sup>p773</sup> to its [submission value](#)<sup>p773</sup>.
5. Otherwise, if *state* is a [FormData](#) object, set *element*'s [state](#)<sup>p773</sup> to a [clone](#) of *state*'s [entry list](#).
6. Otherwise, set *element*'s [state](#)<sup>p773</sup> to *state*.

Each [form-associated custom element](#)<sup>p760</sup> has validity flags named `valueMissing`, `typeMismatch`, `patternMismatch`, `tooLong`, `tooShort`, `rangeUnderflow`, `rangeOverflow`, `stepMismatch`, and `customError`. They are false initially.

Each [form-associated custom element](#)<sup>p760</sup> has a **validation message** string. It is the empty string initially.

Each [form-associated custom element](#)<sup>p760</sup> has a **validation anchor** element. It is null initially.

The [setValidity\(flags, message, anchor\)](#) method steps are:

1. Let *element* be [this](#)'s [target element](#)<sup>p772</sup>.
2. If *element* is not a [form-associated custom element](#)<sup>p760</sup>, then throw a ["NotSupportedError"](#) [DOMException](#).

3. If *flags* contains one or more true values and *message* is not given or is the empty string, then throw a [TypeError](#).
4. For each entry *flag* → *value* of *flags*, set *element*'s validity flag with the name *flag* to *value*.
5. Set *element*'s [validation message](#)<sup>p773</sup> to the empty string if *message* is not given or all of *element*'s validity flags are false, or to *message* otherwise.
6. If *element*'s `customError` validity flag is true, then set *element*'s [custom validity error message](#)<sup>p622</sup> to *element*'s [validation message](#)<sup>p773</sup>. Otherwise, set *element*'s [custom validity error message](#)<sup>p622</sup> to the empty string.
7. Set *element*'s [validation anchor](#)<sup>p773</sup> to null if *anchor* is not given. Otherwise, if *anchor* is not a [shadow-including descendant](#) of *element*, then throw a ["NotFoundError"](#) [DOMException](#). Otherwise, set *element*'s [validation anchor](#)<sup>p773</sup> to *anchor*.

The [validationMessage](#) getter steps are:

1. Let *element* be [this's target element](#)<sup>p772</sup>.
2. If *element* is not a [form-associated custom element](#)<sup>p760</sup>, then throw a ["NotSupportedError"](#) [DOMException](#).
3. Return *element*'s [validation message](#)<sup>p773</sup>.

The **entry construction algorithm** for a [form-associated custom element](#)<sup>p760</sup>, given an element *element* and an [entry list](#)<sup>p632</sup> *entry list*, consists of the following steps:

1. If *element*'s [submission value](#)<sup>p773</sup> is a [list](#) of [entries](#)<sup>p632</sup>, then [append](#) each item of *element*'s [submission value](#)<sup>p773</sup> to *entry list*, and return.

#### Note

*In this case, user agent does not refer to the [name](#)<sup>p599</sup> content attribute value. An implementation of [form-associated custom element](#)<sup>p760</sup> is responsible to decide names of [entries](#)<sup>p632</sup>. They can be the [name](#)<sup>p599</sup> content attribute value, they can be strings based on the [name](#)<sup>p599</sup> content attribute value, or they can be unrelated to the [name](#)<sup>p599</sup> content attribute.*

2. If the element does not have a [name](#)<sup>p599</sup> attribute specified, or its [name](#)<sup>p599</sup> attribute's value is the empty string, then return.
3. If the element's [submission value](#)<sup>p773</sup> is not null, [create an entry](#)<sup>p632</sup> with the [name](#)<sup>p599</sup> attribute value and the [submission value](#)<sup>p773</sup>, and [append](#) it to *entry list*.

### 4.13.7.4 Accessibility semantics <sup>§ p77</sup><sub>4</sub>

For web developers (non-normative)

**`internals.role`<sup>p0</sup> [ = *value* ]**

Sets or retrieves the default ARIA role for *internals*'s [target element](#)<sup>p772</sup>, which will be used unless the page author overrides it using the [role](#)<sup>p68</sup> attribute.

**`internals.aria`<sup>\*p0</sup> [ = *value* ]**

Sets or retrieves various default ARIA states or property values for *internals*'s [target element](#)<sup>p772</sup>, which will be used unless the page author overrides them using the [aria-\\*](#)<sup>p68</sup> attributes.

Each [custom element](#)<sup>p759</sup> has an **internal content attribute map**, which is a [map](#), initially empty. See the [Requirements related to ARIA and to platform accessibility APIs](#)<sup>p170</sup> section for information on how this impacts platform accessibility APIs.

### 4.13.7.5 Custom state pseudo-class <sup>§ p77</sup><sub>4</sub>

For web developers (non-normative)

**`internals.states`<sup>p775</sup>.`add`(*value*)**

Adds the string *value* to the element's [states set](#)<sup>p775</sup> to be exposed as a pseudo-class.

**`internals.states`<sup>p775</sup>.`has`(*value*)**

Returns true if *value* is in the element's [states set](#)<sup>p775</sup>, otherwise false.

**`internals.statesp775.delete(value)`**

If the element's [states set<sup>p775</sup>](#) has *value*, then it will be removed and true will be returned. Otherwise, false will be returned.

**`internals.statesp775.clear()`**

Removes all values from the element's [states set<sup>p775</sup>](#).

**`for (const stateName of internals.statesp775)`**

**`for (const stateName of internals.statesp775.entries())`**

**`for (const stateName of internals.statesp775.keys())`**

**`for (const stateName of internals.statesp775.values())`**

Iterates over all values in the element's [states set<sup>p775</sup>](#).

**`internals.statesp775.forEach(callback)`**

Iterates over all values in the element's [states set<sup>p775</sup>](#) by calling *callback* once for each value.

**`internals.statesp775.size`**

Returns the number of values in the element's [states set<sup>p775</sup>](#).

Each [custom element<sup>p759</sup>](#) has a **states set**, which is a [CustomStateSet<sup>p775</sup>](#), initially empty.

```
IDL [Exposed=Window]
interface CustomStateSet {
    setlike<DOMString>;
};
```

The **states** getter steps are to return [this's target element<sup>p772</sup>](#)'s [states set<sup>p775</sup>](#).

#### Example

The [states set<sup>p775</sup>](#) can expose boolean states represented by existence/non-existence of string values. If an author wants to expose a state which can have three values, it can be converted to three exclusive boolean states. For example, a state called `readyState` with "loading", "interactive", and "complete" values can be mapped to three exclusive boolean states, "loading", "interactive", and "complete":

```
// Change the readyState from anything to "complete".
this._readyState = "complete";
this._internals.states.delete("loading");
this._internals.states.delete("interactive");
this._internals.states.add("complete");
```

## 4.14 Common idioms without dedicated elements <sup>p77</sup><sub>5</sub>

### 4.14.1 Breadcrumb navigation <sup>p77</sup><sub>5</sub>

This specification does not provide a machine-readable way of describing breadcrumb navigation menus. Authors are encouraged to just use a series of links in a paragraph. The [nav<sup>p211</sup>](#) element can be used to mark the section containing these paragraphs as being navigation blocks.

#### Example

In the following example, the current page can be reached via two paths.

```
<nav>
  <p>
    <a href="/">Main</a> ►
    <a href="/products/">Products</a> ►
    <a href="/products/dishwashers/">Dishwashers</a> ►
```

```

    <a>Second hand</a>
  </p>
  <p>
    <a href="/">Main</a> ▶
    <a href="/second-hand/">Second hand</a> ▶
    <a>Dishwashers</a>
  </p>
</nav>

```

#### 4.14.2 Tag clouds §<sup>p77</sup><sub>6</sub>

This specification does not define any markup specifically for marking up lists of keywords that apply to a group of pages (also known as *tag clouds*). In general, authors are encouraged to either mark up such lists using [ul<sup>p239</sup>](#) elements with explicit inline counts that are then hidden and turned into a presentational effect using a style sheet, or to use SVG.

##### Example

Here, three tags are included in a short tag cloud:

```

<style>
.tag-cloud > li > span { display: none; }
.tag-cloud > li { display: inline; }
.tag-cloud-1 { font-size: 0.7em; }
.tag-cloud-2 { font-size: 0.9em; }
.tag-cloud-3 { font-size: 1.1em; }
.tag-cloud-4 { font-size: 1.3em; }
.tag-cloud-5 { font-size: 1.5em; }

@media speech {
.tag-cloud > li > span { display:inline }
}
</style>
...
<ul class="tag-cloud">
  <li class="tag-cloud-4"><a title="28 instances" href="/t/apple">apple</a> <span>(popular)</span>
  <li class="tag-cloud-2"><a title="6 instances" href="/t/kiwi">kiwi</a> <span>(rare)</span>
  <li class="tag-cloud-5"><a title="41 instances" href="/t/pear">pear</a> <span>(very
popular)</span>
</ul>

```

The actual frequency of each tag is given using the [title<sup>p157</sup>](#) attribute. A CSS style sheet is provided to convert the markup into a cloud of differently-sized words, but for user agents that do not support CSS or are not visual, the markup contains annotations like "(popular)" or "(rare)" to categorize the various tags by frequency, thus enabling all users to benefit from the information.

The [ul<sup>p239</sup>](#) element is used (rather than [ol<sup>p238</sup>](#)) because the order is not particularly important: while the list is in fact ordered alphabetically, it would convey the same information if ordered by, say, the length of the tag.

The [tag<sup>p334</sup>](#) [rel<sup>p303</sup>](#)-keyword is *not* used on these [a<sup>p257</sup>](#) elements because they do not represent tags that apply to the page itself; they are just part of an index listing the tags themselves.

#### 4.14.3 Conversations §<sup>p77</sup><sub>6</sub>

This specification does not define a specific element for marking up conversations, meeting minutes, chat transcripts, dialogues in screenplays, instant message logs, and other situations where different players take turns in discourse.

Instead, authors are encouraged to mark up conversations using [p<sup>p229</sup>](#) elements and punctuation. Authors who need to mark the

speaker for styling purposes are encouraged to use [span<sup>p298</sup>](#) or [b<sup>p292</sup>](#). Paragraphs with their text wrapped in the [i<sup>p291</sup>](#) element can be used for marking up stage directions.

#### Example

This example demonstrates this using an extract from Abbot and Costello's famous sketch, *Who's on first*:

```
<p> Costello: Look, you gotta first baseman?
<p> Abbott: Certainly.
<p> Costello: Who's playing first?
<p> Abbott: That's right.
<p> Costello becomes exasperated.
<p> Costello: When you pay off the first baseman every month, who gets the money?
<p> Abbott: Every dollar of it.
```

#### Example

The following extract shows how an IM conversation log could be marked up, using the [data<sup>p278</sup>](#) element to provide Unix timestamps for each line. Note that the timestamps are provided in a format that the [time<sup>p279</sup>](#) element does not support, so the [data<sup>p278</sup>](#) element is used instead (namely, Unix `time_t` timestamps). Had the author wished to mark up the data using one of the date and time formats supported by the [time<sup>p279</sup>](#) element, that element could have been used instead of [data<sup>p278</sup>](#). This could be advantageous as it would allow data analysis tools to detect the timestamps unambiguously, without coordination with the page author.

```
<p> <data value="1319898155">14:22</data> <b>egof</b> I'm not that nerdy, I've only seen 30% of the
star trek episodes
<p> <data value="1319898192">14:23</data> <b>kaj</b> if you know what percentage of the star trek
episodes you have seen, you are inarguably nerdy
<p> <data value="1319898200">14:23</data> <b>egof</b> it's unarguably
<p> <data value="1319898228">14:23</data> <i>* kaj blinks</i>
<p> <data value="1319898260">14:24</data> <b>kaj</b> you are not helping your case
```

#### Example

HTML does not have a good way to mark up graphs, so descriptions of interactive conversations from games are more difficult to mark up. This example shows one possible convention using [dl<sup>p244</sup>](#) elements to list the possible responses at each point in the conversation. Another option to consider is describing the conversation in the form of a DOT file, and outputting the result as an SVG image to place in the document. [\[DOT\]<sup>p1478</sup>](#)

```
<p> Next, you meet a fisher. You can say one of several greetings:
<dl>
<dt> "Hello there!"
<dd>
<p> She responds with "Hello, how may I help you?"; you can respond with:
<dl>
<dt> "I would like to buy a fish."
<dd> <p> She sells you a fish and the conversation finishes.
<dt> "Can I borrow your boat?"
<dd>
<p> She is surprised and asks "What are you offering in return?".
<dl>
<dt> "Five gold." (if you have enough)
<dt> "Ten gold." (if you have enough)
<dt> "Fifteen gold." (if you have enough)
<dd> <p> She lends you her boat. The conversation ends.
<dt> "A fish." (if you have one)
<dt> "A newspaper." (if you have one)
<dt> "A pebble." (if you have one)
<dd> <p> "No thanks", she replies. Your conversation options
at this point are the same as they were after asking to borrow
her boat, minus any options you've suggested before.
</dl>
```

```

    </dd>
  </dl>
</dd>
<dt> "Vote for me in the next election!"
<dd> <p> She turns away. The conversation finishes.
<dt> "Madam, are you aware that your fish are running away?"
<dd>
  <p> She looks at you skeptically and says "Fish cannot run, miss".
<dl>
  <dt> "You got me!"
  <dd> <p> The fisher sighs and the conversation ends.
  <dt> "Only kidding."
  <dd> <p> "Good one!" she retorts. Your conversation options at this
    point are the same as those following "Hello there!" above.
  <dt> "Oh, then what are they doing?"
  <dd> <p> She looks at her fish, giving you an opportunity to steal
    her boat, which you do. The conversation ends.
</dl>
</dd>
</dl>

```

### Example

In some games, conversations are simpler: each character merely has a fixed set of lines that they say. In this example, a game FAQ/walkthrough lists some of the known possible responses for each character:

```

<section>
<h1>Dialogue</h1>
<p><small>Some characters repeat their lines in order each time you interact
with them, others randomly pick from amongst their lines. Those who respond in
order have numbered entries in the lists below.</small>
<h2>The Shopkeeper</h2>
<ul>
  <li>How may I help you?
  <li>Fresh apples!
  <li>A loaf of bread for madam?
</ul>
<h2>The pilot</h2>
<p>Before the accident:
<ul>
  <li>I'm about to fly out, sorry!
  <li>Sorry, I'm just waiting for flight clearance and then I'll be off!
</ul>
<p>After the accident:
<ol>
  <li>I'm about to fly out, sorry!
  <li>Ok, I'm not leaving right now, my plane is being cleaned.
  <li>Ok, it's not being cleaned, it needs a minor repair first.
  <li>Ok, ok, stop bothering me! Truth is, I had a crash.
</ol>
<h2>Clan Leader</h2>
<p>During the first clan meeting:
<ul>
  <li>Hey, have you seen my daughter? I bet she's up to something nefarious again...
  <li>Nice weather we're having today, eh?
  <li>The name is Bailey, Jeff Bailey. How can I help you today?
  <li>A glass of water? Fresh from the well!
</ul>
<p>After the earthquake:
<ol>

```

```

<li>Everyone is safe in the shelter, we just have to put out the fire!
<li>I'll go and tell the fire brigade, you keep hosing it down!
</ol>
</section>

```

#### 4.14.4 Footnotes <sup>p77</sup><sub>9</sub>

HTML does not have a dedicated mechanism for marking up footnotes. Here are the suggested alternatives.

For short inline annotations, the [title<sup>p157</sup>](#) attribute could be used.

##### Example

In this example, two parts of a dialogue are annotated with footnote-like content using the [title<sup>p157</sup>](#) attribute.

```

<p> <b>Customer</b>: Hello! I wish to register a complaint. Hello. Miss?
<p> <b>Shopkeeper</b>: <span title="Colloquial pronunciation of 'What do you'"
>Watcha</span> mean, miss?
<p> <b>Customer</b>: Uh, I'm sorry, I have a cold. I wish to make a complaint.
<p> <b>Shopkeeper</b>: Sorry, <span title="This is, of course, a lie.">we're
closing for lunch</span>.

```

##### Note

Unfortunately, relying on the [title<sup>p157</sup>](#) attribute is currently discouraged as many user agents do not expose the attribute in an accessible manner as required by this specification (e.g. requiring a pointing device such as a mouse to cause a tooltip to appear, which excludes keyboard-only users and touch-only users, such as anyone with a modern phone or tablet).

##### Note

If the [title<sup>p157</sup>](#) attribute is used, CSS can be used to draw the reader's attention to the elements with the attribute.

##### Example

For example, the following CSS places a dashed line below elements that have a [title<sup>p157</sup>](#) attribute.

```

CSS [title] { border-bottom: thin dashed; }

```

For longer annotations, the [a<sup>p257</sup>](#) element should be used, pointing to an element later in the document. The convention is that the contents of the link be a number in square brackets.

##### Example

In this example, a footnote in the dialogue links to a paragraph below the dialogue. The paragraph then reciprocally links back to the dialogue, allowing the user to return to the location of the footnote.

```

<p> Announcer: Number 16: The <i>hand</i>.
<p> Interviewer: Good evening. I have with me in the studio tonight
Mr Norman St John Polevaulter, who for the past few years has been
contradicting people. Mr Polevaulter, why <em>do</em> you
contradict people?
<p> Norman: I don't. <sup><a href="#fn1" id="r1">[1]</a></sup>
<p> Interviewer: You told me you did!
...
<section>

```

```
<p id="fn1"><a href="#r1">[1]</a> This is, naturally, a lie,
but paradoxically if it were true he could not say so without
contradicting the interviewer and thus making it false.</p>
</section>
```

For side notes, longer annotations that apply to entire sections of the text rather than just specific words or sentences, the [aside<sup>p214</sup>](#) element should be used.

#### Example

In this example, a sidebar is given after a dialogue, giving it some context.

```
<p> <span class="speaker">Customer</span>: I will not buy this record, it is scratched.
<p> <span class="speaker">Shopkeeper</span>: I'm sorry?
<p> <span class="speaker">Customer</span>: I will not buy this record, it is scratched.
<p> <span class="speaker">Shopkeeper</span>: No no no, this's'a tobacconist's.
<aside>
  <p>In 1970, the British Empire lay in ruins, and foreign
  nationalists frequented the streets – many of them Hungarians
  (not the streets – the foreign nationals). Sadly, Alexander
  Yalt has been publishing incompetently-written phrase books.
</aside>
```

For figures or tables, footnotes can be included in the relevant [figcaption<sup>p252</sup>](#) or [caption<sup>p486</sup>](#) element, or in surrounding prose.

#### Example

In this example, a table has cells with footnotes that are given in prose. A [figure<sup>p249</sup>](#) element is used to give a single legend to the combination of the table and its footnotes.

```
<figure>
  <figcaption>Table 1. Alternative activities for knights.</figcaption>
  <table>
    <tr>
      <th> Activity
      <th> Location
      <th> Cost
    </tr>
    <tr>
      <td> Dance
      <td> Wherever possible
      <td> £0<sup><a href="#fn1">1</a></sup>
    </tr>
    <tr>
      <td> Routines, chorus scenes<sup><a href="#fn2">2</a></sup>
      <td> Undisclosed
      <td> Undisclosed
    </tr>
    <tr>
      <td> Dining<sup><a href="#fn3">3</a></sup>
      <td> Camelot
      <td> Cost of ham, jam, and spam<sup><a href="#fn4">4</a></sup>
    </tr>
  </table>
  <p id="fn1">1. Assumed.</p>
  <p id="fn2">2. Footwork impeccable.</p>
  <p id="fn3">3. Quality described as "well".</p>
  <p id="fn4">4. A lot.</p>
</figure>
```

## 4.15 Disabled elements §<sup>p78</sup><sub>1</sub>

An element is said to be **actually disabled** if it is one of the following:

- a [button<sup>p566</sup>](#) element that is [disabled<sup>p601</sup>](#)
- an [input<sup>p520</sup>](#) element that is [disabled<sup>p601</sup>](#)
- a [select<sup>p568</sup>](#) element that is [disabled<sup>p601</sup>](#)
- a [textarea<sup>p579</sup>](#) element that is [disabled<sup>p601</sup>](#)
- an [optgroup<sup>p576</sup>](#) element that has a [disabled<sup>p576</sup>](#) attribute
- an [option<sup>p577</sup>](#) element that is [disabled<sup>p578</sup>](#)
- a [fieldset<sup>p594</sup>](#) element that is a [disabled fieldset<sup>p594</sup>](#)
- a [form-associated custom element<sup>p760</sup>](#) that is [disabled<sup>p601</sup>](#)

### Note

*This definition is used to determine what elements are [focusable<sup>p837</sup>](#) and which elements match the [:enabled<sup>p784</sup>](#) and [:disabled<sup>p784</sup>](#) pseudo classes.*

## 4.16 Matching HTML elements using selectors and CSS §<sup>p78</sup><sub>1</sub>

### 4.16.1 Case-sensitivity of the CSS '[attr\(\)](#)' function §<sup>p78</sup><sub>1</sub>

*CSS Values and Units* leaves the case-sensitivity of attribute names for the purpose of the '[attr\(\)](#)' function to be defined by the host language. [\[CSSVALUES\]<sup>p1477</sup>](#)

When comparing the attribute name part of a CSS '[attr\(\)](#)' function to the names of namespace-less attributes on [HTML elements<sup>p45</sup>](#) in [HTML documents](#), the name part of the CSS '[attr\(\)](#)' function must first be [converted to ASCII lowercase](#). The same function when compared to other attributes must be compared according to its original case. In both cases, to match the values must be [identical to](#) each other (and therefore the comparison is case sensitive).

### Note

*This is the same as comparing the name part of a CSS [attribute selector](#), specified in the next section.*

### 4.16.2 Case-sensitivity of selectors §<sup>p78</sup><sub>1</sub>

*Selectors* leaves the case-sensitivity of element names, attribute names, and attribute values to be defined by the host language. [\[SELECTORS\]<sup>p1482</sup>](#)

When comparing a CSS element [type selector](#) to the names of [HTML elements<sup>p45</sup>](#) in [HTML documents](#), the CSS element [type selector](#) must first be [converted to ASCII lowercase](#). The same selector when compared to other elements must be compared according to its original case. In both cases, to match the values must be [identical to](#) each other (and therefore the comparison is case sensitive).

When comparing the name part of a CSS [attribute selector](#) to the names of attributes on [HTML elements<sup>p45</sup>](#) in [HTML documents](#), the name part of the CSS [attribute selector](#) must first be [converted to ASCII lowercase](#). The same selector when compared to other attributes must be compared according to its original case. In both cases, the comparison is case-sensitive.

[Attribute selectors](#) on an [HTML element<sup>p45</sup>](#) in an [HTML document](#) must treat the *values* of attributes with the following names as [ASCII case-insensitive](#):

- accept
- accept-charset
- align
- alink
- axis
- bgcolor

- charset
- checked
- clear
- codetype
- color
- compact
- declare
- defer
- dir
- direction
- disabled
- enctype
- face
- frame
- hreflang
- http-equiv
- lang
- language
- link
- media
- method
- multiple
- nohref
- noresize
- noshade
- nowrap
- readonly
- rel
- rev
- rules
- scope
- scrolling
- selected
- shape
- target
- text
- type
- valign
- valuetype
- vlink

#### Example

For example, the selector `[bgcolor="#ffffff"]` will match any HTML element with a `bgcolor` attribute with values including `#ffffff`, `#FFFFFF` and `#fffFFF`. This happens even if `bgcolor` has no effect for a given element (e.g., `div`<sup>p256</sup>).

The selector `[type=a s]` will match any HTML element with a `type` attribute whose value is `a`, but not whose value is `A`, due to the `s` flag.

All other attribute values and everything else must be treated as entirely [identical to](#) each other for the purposes of selector matching. This includes:

- [IDs](#) and [classes](#) in [no-quirks mode](#) and [limited-quirks mode](#)
- the names of elements not in the [HTML namespace](#)
- the names of [HTML elements](#)<sup>p45</sup> in [XML documents](#)
- the names of attributes of elements not in the [HTML namespace](#)
- the names of attributes of [HTML elements](#)<sup>p45</sup> in [XML documents](#)
- the names of attributes that themselves have namespaces

#### Note

*Selectors defines that ID and class selectors (such as `#foo` and `.bar`), when matched against elements in documents that are in [quirks mode](#), will be matched in an [ASCII case-insensitive](#) manner. However, this does not apply for attribute selectors with `"id"` or `"class"` as the name part. The selector `[class="foobar"]` will treat its value as case-sensitive even in [quirks mode](#).*

### 4.16.3 Pseudo-classes <sup>§ p78</sup> <sub>2</sub>

There are a number of dynamic selectors that can be used with HTML. This section defines when these selectors match HTML

elements. [\[SELECTORS\]](#)<sup>p1482</sup> [\[CSSUI\]](#)<sup>p1477</sup>

## :defined

The [:defined](#)<sup>p783</sup> [pseudo-class](#) must match any element that is [defined](#).

## :link

## :visited

All [a](#)<sup>p257</sup> elements that have an [href](#)<sup>p303</sup> attribute, and all [area](#)<sup>p471</sup> elements that have an [href](#)<sup>p303</sup> attribute, must match one of [:link](#)<sup>p783</sup> and [:visited](#)<sup>p783</sup>.

Other specifications might apply more specific rules regarding how these elements are to match these [pseudo-classes](#), to mitigate some privacy concerns that apply with straightforward implementations of this requirement.

## :active

The [:active](#)<sup>p783</sup> [pseudo-class](#) is defined to match an element “while an element is **being activated** by the user”.

To determine whether a particular element is [being activated](#)<sup>p783</sup> for the purposes of defining the [:active](#)<sup>p783</sup> [pseudo-class](#) only, an HTML user agent must use the first relevant entry in the following list.

If the element is a [button](#)<sup>p566</sup> element

If the element is an [input](#)<sup>p520</sup> element whose [type](#)<sup>p523</sup> attribute is in the [Submit Button](#)<sup>p546</sup>, [Image Button](#)<sup>p547</sup>, [Reset Button](#)<sup>p549</sup>, or [Button](#)<sup>p550</sup> state

If the element is an [a](#)<sup>p257</sup> element that has an [href](#)<sup>p303</sup> attribute

If the element is an [area](#)<sup>p471</sup> element that has an [href](#)<sup>p303</sup> attribute

If the element is [focusable](#)<sup>p837</sup>

The element is [being activated](#)<sup>p783</sup> if it is [in a formal activation state](#)<sup>p783</sup>.

### Example

For example, if the user is using a keyboard to push a [button](#)<sup>p566</sup> element by pressing the space bar, the element would match this [pseudo-class](#) in between the time that the element received the [keydown](#) event and the time the element received the [keyup](#) event.

If the element is [being actively pointed at](#)<sup>p783</sup>

The element is [being activated](#)<sup>p783</sup>.

An element is said to be **in a formal activation state** between the time the user begins to indicate an intent to trigger the element's [activation behavior](#) and either the time the user stops indicating an intent to trigger the element's [activation behavior](#), or the time the element's [activation behavior](#) has finished running, whichever comes first.

An element is said to be **being actively pointed at** while the user indicates the element using a pointing device while that pointing device is in the “down” state (e.g. for a mouse, between the time the mouse button is pressed and the time it is depressed; for a finger in a multitouch environment, while the finger is touching the display surface).

### Note

Per the definition in Selectors, [:active](#)<sup>p783</sup> also matches [flat tree](#) ancestors of elements that are [being activated](#)<sup>p783</sup>.  
[\[SELECTORS\]](#)<sup>p1482</sup>

Additionally, any element that is the [labeled control](#)<sup>p518</sup> of a [label](#)<sup>p518</sup> element that is currently matching [:active](#)<sup>p783</sup>, also matches [:active](#)<sup>p783</sup>. (But, it does not count as being [being activated](#)<sup>p783</sup>.)

## :hover

The [:hover](#)<sup>p783</sup> [pseudo-class](#) is defined to match an element “while the user **designates** an element with a pointing device”. For the purposes of defining the [:hover](#)<sup>p783</sup> [pseudo-class](#) only, an HTML user agent must consider an element as being one that the user [designates](#)<sup>p783</sup> if it is an element that the user indicates using a pointing device.

### Note

Per the definition in Selectors, [:hover](#)<sup>p783</sup> also matches [flat tree](#) ancestors of elements that are [designated](#)<sup>p783</sup>.  
[\[SELECTORS\]](#)<sup>p1482</sup>

Additionally, any element that is the [labeled control](#)<sup>p518</sup> of a [label](#)<sup>p518</sup> element that is currently matching [:hover](#)<sup>p783</sup>, also matches

[:hover](#)<sup>p783</sup>. (But, it does not count as being [designated](#)<sup>p783</sup>.)

#### Example

Consider in particular a fragment such as:

```
<p> <label for=c> <input id=a> </label> <span id=b> <input id=c> </span> </p>
```

If the user designates the element with ID "a" with their pointing device, then the [p](#)<sup>p229</sup> element (and all its ancestors not shown in the snippet above), the [label](#)<sup>p518</sup> element, the element with ID "a", and the element with ID "c" will match the [:hover](#)<sup>p783</sup> [pseudo-class](#). The element with ID "a" matches it by being [designated](#)<sup>p783</sup>; the [label](#)<sup>p518</sup> and [p](#)<sup>p229</sup> elements match it because of the condition in *Selectors* about flat tree ancestors; and the element with ID "c" matches it through the additional condition above on [labeled controls](#)<sup>p518</sup> (i.e., its [label](#)<sup>p518</sup> element matches [:hover](#)<sup>p783</sup>). However, the element with ID "b" does *not* match [:hover](#)<sup>p783</sup>: its flat tree descendant is not designated, even though that flat tree descendant matches [:hover](#)<sup>p783</sup>.

#### :focus

For the purposes of the CSS [:focus](#)<sup>p784</sup> [pseudo-class](#), an **element has the focus** when:

- it is not itself a [navigable container](#)<sup>p991</sup>; and
- any of the following are true:
  - it is one of the elements listed in the [current focus chain of the top-level traversable](#)<sup>p836</sup>; or
  - its [shadow root](#) *shadowRoot* is not null and *shadowRoot* is the [root](#) of at least one element that [has the focus](#)<sup>p784</sup>.

#### :target

For the purposes of the CSS [:target](#)<sup>p784</sup> [pseudo-class](#), the [Document](#)<sup>p130</sup>'s *target elements* are a list containing the [Document](#)<sup>p130</sup>'s [target element](#)<sup>p1054</sup>, if it is not null, or containing no elements, if it is. [\[SELECTORS\]](#)<sup>p1482</sup>

#### :popover-open

The [:popover-open](#)<sup>p784</sup> [pseudo-class](#) is defined to match any [HTML element](#)<sup>p45</sup> whose [popover](#)<sup>p886</sup> attribute is not in the [no popover state](#)<sup>p887</sup> and whose [popover visibility state](#)<sup>p887</sup> is [showing](#)<sup>p887</sup>.

#### :enabled

The [:enabled](#)<sup>p784</sup> [pseudo-class](#) must match any [button](#)<sup>p566</sup>, [input](#)<sup>p520</sup>, [select](#)<sup>p568</sup>, [textarea](#)<sup>p579</sup>, [optgroup](#)<sup>p576</sup>, [option](#)<sup>p577</sup>, [fieldset](#)<sup>p594</sup> element, or [form-associated custom element](#)<sup>p760</sup> that is not [actually disabled](#)<sup>p781</sup>.

#### :disabled

The [:disabled](#)<sup>p784</sup> [pseudo-class](#) must match any element that is [actually disabled](#)<sup>p781</sup>.

#### :checked

The [:checked](#)<sup>p784</sup> [pseudo-class](#) must match any element falling into one of the following categories:

- [input](#)<sup>p520</sup> elements whose [type](#)<sup>p523</sup> attribute is in the [Checkbox](#)<sup>p542</sup> state and whose [checkedness](#)<sup>p597</sup> state is true
- [input](#)<sup>p520</sup> elements whose [type](#)<sup>p523</sup> attribute is in the [Radio Button](#)<sup>p543</sup> state and whose [checkedness](#)<sup>p597</sup> state is true
- [option](#)<sup>p577</sup> elements whose [selectedness](#)<sup>p578</sup> is true

#### :indeterminate

The [:indeterminate](#)<sup>p784</sup> [pseudo-class](#) must match any element falling into one of the following categories:

- [input](#)<sup>p520</sup> elements whose [type](#)<sup>p523</sup> attribute is in the [Checkbox](#)<sup>p542</sup> state and whose [indeterminate](#)<sup>p526</sup> IDL attribute is set to true
- [input](#)<sup>p520</sup> elements whose [type](#)<sup>p523</sup> attribute is in the [Radio Button](#)<sup>p543</sup> state and whose [radio button group](#)<sup>p543</sup> contains no [input](#)<sup>p520</sup> elements whose [checkedness](#)<sup>p597</sup> state is true.
- [progress](#)<sup>p587</sup> elements with no [value](#)<sup>p587</sup> content attribute

#### :default

The [:default](#)<sup>p784</sup> [pseudo-class](#) must match any element falling into one of the following categories:

- [Submit buttons](#)<sup>p514</sup> that are [default buttons](#)<sup>p628</sup> of their [form owner](#)<sup>p598</sup>.
- [input](#)<sup>p520</sup> elements to which the [checked](#)<sup>p525</sup> attribute applies and that have a [checked](#)<sup>p525</sup> attribute
- [option](#)<sup>p577</sup> elements that have a [selected](#)<sup>p578</sup> attribute

### **:placeholder-shown**

The [:placeholder-shown](#)<sup>p785</sup> [pseudo-class](#) must match any element falling into one of the following categories:

- [input](#)<sup>p520</sup> elements that have a [placeholder](#)<sup>p559</sup> attribute whose value is currently being presented to the user
- [textarea](#)<sup>p579</sup> elements that have a [placeholder](#)<sup>p583</sup> attribute whose value is currently being presented to the user

### **:valid**

The [:valid](#)<sup>p785</sup> [pseudo-class](#) must match any element falling into one of the following categories:

- elements that are [candidates for constraint validation](#)<sup>p622</sup> and that [satisfy their constraints](#)<sup>p623</sup>
- [form](#)<sup>p514</sup> elements that are not the [form owner](#)<sup>p598</sup> of any elements that themselves are [candidates for constraint validation](#)<sup>p622</sup> but do not [satisfy their constraints](#)<sup>p623</sup>
- [fieldset](#)<sup>p594</sup> elements that have no descendant elements that themselves are [candidates for constraint validation](#)<sup>p622</sup> but do not [satisfy their constraints](#)<sup>p623</sup>

### **:invalid**

The [:invalid](#)<sup>p785</sup> [pseudo-class](#) must match any element falling into one of the following categories:

- elements that are [candidates for constraint validation](#)<sup>p622</sup> but that do not [satisfy their constraints](#)<sup>p623</sup>
- [form](#)<sup>p514</sup> elements that are the [form owner](#)<sup>p598</sup> of one or more elements that themselves are [candidates for constraint validation](#)<sup>p622</sup> but do not [satisfy their constraints](#)<sup>p623</sup>
- [fieldset](#)<sup>p594</sup> elements that have one or more descendant elements that themselves are [candidates for constraint validation](#)<sup>p622</sup> but do not [satisfy their constraints](#)<sup>p623</sup>

### **:user-valid**

The [:user-valid](#)<sup>p785</sup> [pseudo-class](#) must match [input](#)<sup>p520</sup>, [textarea](#)<sup>p579</sup>, and [select](#)<sup>p568</sup> elements whose [user validity](#)<sup>p597</sup> is true, are [candidates for constraint validation](#)<sup>p622</sup>, and that [satisfy their constraints](#)<sup>p623</sup>.

### **:user-invalid**

The [:user-invalid](#)<sup>p785</sup> [pseudo-class](#) must match [input](#)<sup>p520</sup>, [textarea](#)<sup>p579</sup>, and [select](#)<sup>p568</sup> elements whose [user validity](#)<sup>p597</sup> is true, are [candidates for constraint validation](#)<sup>p622</sup> but do not [satisfy their constraints](#)<sup>p623</sup>.

### **:in-range**

The [:in-range](#)<sup>p785</sup> [pseudo-class](#) must match all elements that are [candidates for constraint validation](#)<sup>p622</sup>, [have range limitations](#)<sup>p556</sup>, and that are neither [suffering from an underflow](#)<sup>p623</sup> nor [suffering from an overflow](#)<sup>p623</sup>.

### **:out-of-range**

The [:out-of-range](#)<sup>p785</sup> [pseudo-class](#) must match all elements that are [candidates for constraint validation](#)<sup>p622</sup>, [have range limitations](#)<sup>p556</sup>, and that are either [suffering from an underflow](#)<sup>p623</sup> or [suffering from an overflow](#)<sup>p623</sup>.

### **:required**

The [:required](#)<sup>p785</sup> [pseudo-class](#) must match any element falling into one of the following categories:

- [input](#)<sup>p520</sup> elements that are [required](#)<sup>p552</sup>
- [select](#)<sup>p568</sup> elements that have a [required](#)<sup>p570</sup> attribute
- [textarea](#)<sup>p579</sup> elements that have a [required](#)<sup>p582</sup> attribute

### **:optional**

The [:optional](#)<sup>p785</sup> [pseudo-class](#) must match any element falling into one of the following categories:

- [input](#)<sup>p520</sup> elements to which the [required](#)<sup>p552</sup> attribute applies that are not [required](#)<sup>p552</sup>
- [select](#)<sup>p568</sup> elements that do not have a [required](#)<sup>p570</sup> attribute

- [textarea<sup>p579</sup>](#) elements that do not have a [required<sup>p582</sup>](#) attribute

MDN

## :autofill

### :-webkit-autofill

The [:autofill<sup>p786</sup>](#) and [:-webkit-autofill<sup>p786</sup>](#) [pseudo-classes](#) must match [input<sup>p520</sup>](#) elements which have been autofilled by user agent. These pseudo-classes must stop matching if the user edits the autofilled field.

#### Note

*One way such autofilling might happen is via the [autocomplete<sup>p604</sup>](#) attribute, but user agents could autofill even without that attribute being involved.*

## :read-only

### :read-write

The [:read-write<sup>p786</sup>](#) [pseudo-class](#) must match any element falling into one of the following categories, which for the purposes of Selectors are thus considered *user-alterable*: [\[SELECTORS\]<sup>p1482</sup>](#)

- [input<sup>p520</sup>](#) elements to which the [readonly<sup>p551</sup>](#) attribute applies, and that are [mutable<sup>p597</sup>](#) (i.e. that do not have the [readonly<sup>p551</sup>](#) attribute specified and that are not [disabled<sup>p601</sup>](#))
- [textarea<sup>p579</sup>](#) elements that do not have a [readonly<sup>p581</sup>](#) attribute, and that are not [disabled<sup>p601</sup>](#)
- elements that are [editing hosts<sup>p855</sup>](#) or [editable](#) and are neither [input<sup>p520</sup>](#) elements nor [textarea<sup>p579</sup>](#) elements

The [:read-only<sup>p786</sup>](#) [pseudo-class](#) must match all other [HTML elements<sup>p45</sup>](#).

## :modal

The [:modal<sup>p786</sup>](#) [pseudo-class](#) must match any element falling into one of the following categories:

- [dialog<sup>p646</sup>](#) elements whose [is modal<sup>p652</sup>](#) flag is true
- elements whose [fullscreen flag](#) is true

MDN

## :dir(ltr)

The [:dir\(ltr\)<sup>p786</sup>](#) [pseudo-class](#) must match all elements whose [directionality<sup>p160</sup>](#) is 'ltr<sup>p160</sup>'.

## :dir(rtl)

The [:dir\(rtl\)<sup>p786</sup>](#) [pseudo-class](#) must match all elements whose [directionality<sup>p160</sup>](#) is 'rtl<sup>p160</sup>'.

## Custom state pseudo-class

The [:state\(identifier\)<sup>p786</sup>](#) [pseudo-class](#) must match all [custom element<sup>p759</sup>](#)s whose [states set<sup>p775</sup>](#)'s [set entries](#) contains *identifier*.

## :playing

The [:playing<sup>p786</sup>](#) [pseudo-class](#) must match all [media elements<sup>p414</sup>](#) whose [paused<sup>p436</sup>](#) attribute is false.

## :paused

The [:paused<sup>p786</sup>](#) [pseudo-class](#) must match all [media elements<sup>p414</sup>](#) whose [paused<sup>p436</sup>](#) attribute is true.

## :seeking

The [:seeking<sup>p786</sup>](#) [pseudo-class](#) must match all [media elements<sup>p414</sup>](#) whose [seeking<sup>p443</sup>](#) attribute is true.

## :buffering

The [:buffering<sup>p786</sup>](#) [pseudo-class](#) must match all [media elements<sup>p414</sup>](#) whose [paused<sup>p436</sup>](#) attribute is false, [networkState<sup>p418</sup>](#) attribute is [NETWORK\\_LOADING<sup>p418</sup>](#), and ready state is [HAVE\\_CURRENT\\_DATA<sup>p433</sup>](#) or less.

## :stalled

The [:stalled<sup>p786</sup>](#) [pseudo-class](#) must match all [media elements<sup>p414</sup>](#) that match the [:buffering<sup>p786</sup>](#) [pseudo-class](#) and whose [is currently stalled<sup>p419</sup>](#) is true.

## :muted

The [:muted<sup>p786</sup>](#) [pseudo-class](#) must match all [media elements<sup>p414</sup>](#) that are [muted<sup>p465</sup>](#).

### **:volume-locked**

The [:volume-locked](#)<sup>p787</sup> [pseudo-class](#) must match all [media elements](#)<sup>p414</sup> when the user agent's [volume locked](#)<sup>p465</sup> is true.

#### Note

*This specification does not define when an element matches the `:lang()` dynamic [pseudo-class](#), as it is defined in sufficient detail in a language-agnostic fashion in [Selectors](#). [\[SELECTORS\]](#)<sup>p1482</sup>*

## 5 Microdata <sup>§ p78</sup><sub>8</sub>

### 5.1 Introduction <sup>§ p78</sup><sub>8</sub>

#### 5.1.1 Overview <sup>§ p78</sup><sub>8</sub>

*This section is non-normative.*

Sometimes, it is desirable to annotate content with specific machine-readable labels, e.g. to allow generic scripts to provide services that are customized to the page, or to enable content from a variety of cooperating authors to be processed by a single script in a consistent manner.

For this purpose, authors can use the microdata features described in this section. Microdata allows nested groups of name-value pairs to be added to documents, in parallel with the existing content.

#### 5.1.2 The basic syntax <sup>§ p78</sup><sub>8</sub>

*This section is non-normative.*

At a high level, microdata consists of a group of name-value pairs. The groups are called [items](#)<sup>p793</sup>, and each name-value pair is a property. Items and properties are represented by regular elements.

To create an item, the [itemscope](#)<sup>p793</sup> attribute is used.

To add a property to an item, the [itemprop](#)<sup>p795</sup> attribute is used on one of the [item's](#)<sup>p793</sup> descendants.

#### Example

Here there are two items, each of which has the property "name":

```
<div itemscope>
  <p>My name is <span itemprop="name">Elizabeth</span>.</p>
</div>

<div itemscope>
  <p>My name is <span itemprop="name">Daniel</span>.</p>
</div>
```

Markup without the microdata-related attributes does not have any effect on the microdata model.

#### Example

These two examples are exactly equivalent, at a microdata level, as the previous two examples respectively:

```
<div itemscope>
  <p>My <em>name</em> is <span itemprop="name">E<strong>liz</strong>abeth</span>.</p>
</div>

<section>
  <div itemscope>
    <aside>
      <p>My name is <span itemprop="name"><a href="/?user=daniel">Daniel</a></span>.</p>
    </aside>
  </div>
</section>
```

Properties generally have values that are strings.

#### Example

Here the item has three properties:

```
<div itemscope>
  <p>My name is <span itemprop="name">Neil</span>.</p>
  <p>My band is called <span itemprop="band">Four Parts Water</span>.</p>
  <p>I am <span itemprop="nationality">British</span>.</p>
</div>
```

When a string value is a [URL](#), it is expressed using the [a<sup>p257</sup>](#) element and its [href<sup>p303</sup>](#) attribute, the [img<sup>p346</sup>](#) element and its [src<sup>p347</sup>](#) attribute, or other elements that link to or embed external resources.

#### Example

In this example, the item has one property, "image", whose value is a URL:

```
<div itemscope>
  
</div>
```

When a string value is in some machine-readable format unsuitable for human consumption, it is expressed using the [value<sup>p279</sup>](#) attribute of the [data<sup>p278</sup>](#) element, with the human-readable version given in the element's contents.

#### Example

Here, there is an item with a property whose value is a product ID. The ID is not human-friendly, so the product's name is used the human-visible text instead of the ID.

```
<h1 itemscope>
  <data itemprop="product-id" value="9678A0U879">The Instigator 2000</data>
</h1>
```

For numeric data, the [meter<sup>p589</sup>](#) element and its [value<sup>p590</sup>](#) attribute can be used instead.

#### Example

Here a rating is given using a [meter<sup>p589</sup>](#) element.

```
<div itemscope itemtype="http://schema.org/Product">
  <span itemprop="name">Panasonic White 60L Refrigerator</span>
  
  <div itemprop="aggregateRating"
    itemscope itemtype="http://schema.org/AggregateRating">
    <meter itemprop="ratingValue" min=0 value=3.5 max=5>Rated 3.5/5</meter>
    (based on <span itemprop="reviewCount">11</span> customer reviews)
  </div>
</div>
```

Similarly, for date- and time-related data, the [time<sup>p279</sup>](#) element and its [datetime<sup>p280</sup>](#) attribute can be used instead.

#### Example

In this example, the item has one property, "birthday", whose value is a date:

```
<div itemscope>
  I was born on <time itemprop="birthday" datetime="2009-05-10">May 10th 2009</time>.
</div>
```

Properties can also themselves be groups of name-value pairs, by putting the [itemscope<sup>p793</sup>](#) attribute on the element that declares the property.

Items that are not part of others are called [top-level microdata items](#)<sup>p798</sup>.

#### Example

In this example, the outer item represents a person, and the inner one represents a band:

```
<div itemscope>
  <p>Name: <span itemprop="name">Amanda</span></p>
  <p>Band: <span itemprop="band" itemscope> <span itemprop="name">Jazz Band</span> (<span
itemprop="size">12</span> players)</span></p>
</div>
```

The outer item here has two properties, "name" and "band". The "name" is "Amanda", and the "band" is an item in its own right, with two properties, "name" and "size". The "name" of the band is "Jazz Band", and the "size" is "12".

The outer item in this example is a top-level microdata item.

Properties that are not descendants of the element with the [itemscope](#)<sup>p793</sup> attribute can be associated with the [item](#)<sup>p793</sup> using the [itemref](#)<sup>p794</sup> attribute. This attribute takes a list of IDs of elements to crawl in addition to crawling the children of the element with the [itemscope](#)<sup>p793</sup> attribute.

#### Example

This example is the same as the previous one, but all the properties are separated from their [items](#)<sup>p793</sup>:

```
<div itemscope id="amanda" itemref="a b"></div>
<p id="a">Name: <span itemprop="name">Amanda</span></p>
<div id="b" itemprop="band" itemscope itemref="c"></div>
<div id="c">
  <p>Band: <span itemprop="name">Jazz Band</span></p>
  <p>Size: <span itemprop="size">12</span> players</p>
</div>
```

This gives the same result as the previous example. The first item has two properties, "name", set to "Amanda", and "band", set to another item. That second item has two further properties, "name", set to "Jazz Band", and "size", set to "12".

An [item](#)<sup>p793</sup> can have multiple properties with the same name and different values.

#### Example

This example describes an ice cream, with two flavors:

```
<div itemscope>
  <p>Flavors in my favorite ice cream:</p>
  <ul>
    <li itemprop="flavor">Lemon sorbet</li>
    <li itemprop="flavor">Apricot sorbet</li>
  </ul>
</div>
```

This thus results in an item with two properties, both "flavor", having the values "Lemon sorbet" and "Apricot sorbet".

An element introducing a property can also introduce multiple properties at once, to avoid duplication when some of the properties have the same value.

#### Example

Here we see an item with two properties, "favorite-color" and "favorite-fruit", both set to the value "orange":

```
<div itemscope>
  <span itemprop="favorite-color favorite-fruit">orange</span>
</div>
```

It's important to note that there is no relationship between the microdata and the content of the document where the microdata is marked up.

#### Example

There is no semantic difference, for instance, between the following two examples:

```
<figure>
  
  <figcaption><span itemscope><span itemprop="name">The Castle</span></span> (1986)</figcaption>
</figure>
```

```
<span itemscope><meta itemprop="name" content="The Castle"></span>
<figure>
  
  <figcaption>The Castle (1986)</figcaption>
</figure>
```

Both have a figure with a caption, and both, completely unrelated to the figure, have an item with a name-value pair with the name "name" and the value "The Castle". The only difference is that if the user drags the caption out of the document, in the former case, the item will be included in the drag-and-drop data. In neither case is the image in any way associated with the item.

### 5.1.3 Typed items <sup>§ p791</sup>

*This section is non-normative.*

The examples in the previous section show how information could be marked up on a page that doesn't expect its microdata to be re-used. Microdata is most useful, though, when it is used in contexts where other authors and readers are able to cooperate to make new uses of the markup.

For this purpose, it is necessary to give each [item](#)<sup>p793</sup> a type, such as "https://example.com/person", or "https://example.org/cat", or "https://band.example.net/". Types are identified as [URLs](#).

The type for an [item](#)<sup>p793</sup> is given as the value of an [itemtype](#)<sup>p793</sup> attribute on the same element as the [itemscope](#)<sup>p793</sup> attribute.

#### Example

Here, the item's type is "https://example.org/animals#cat":

```
<section itemscope itemtype="https://example.org/animals#cat">
  <h1 itemprop="name">Hedral</h1>
  <p itemprop="desc">Hedral is a male american domestic
  shorthair, with a fluffy black fur with white paws and belly.</p>
  
</section>
```

In this example the "https://example.org/animals#cat" item has three properties, a "name" ("Hedral"), a "desc" ("Hedral is..."), and an "img" ("hedral.jpeg").

The type gives the context for the properties, thus selecting a vocabulary: a property named "class" given for an item with the type "https://census.example/person" might refer to the economic class of an individual, while a property named "class" given for an item with the type "https://example.com/school/teacher" might refer to the classroom a teacher has been assigned. Several types can share a vocabulary. For example, the types "https://example.org/people/teacher" and "https://example.org/people/engineer" could be defined to use the same vocabulary (though maybe some properties would not be especially useful in both cases, e.g. maybe the "https://example.org/people/engineer" type might not typically be used with the "classroom" property). Multiple types defined to use the same vocabulary can be given for a single item by listing the URLs as a space-separated list in the attribute's value. An item cannot be given two types if they do not use the same vocabulary, however.

#### 5.1.4 Global identifiers for items §<sup>p79</sup><sub>2</sub>

*This section is non-normative.*

Sometimes, an [item](#)<sup>p793</sup> gives information about a topic that has a global identifier. For example, books can be identified by their ISBN number.

Vocabularies (as identified by the [itemtype](#)<sup>p793</sup> attribute) can be designed such that [items](#)<sup>p793</sup> get associated with their global identifier in an unambiguous way by expressing the global identifiers as [URLs](#) given in an [itemid](#)<sup>p794</sup> attribute.

The exact meaning of the [URLs](#) given in [itemid](#)<sup>p794</sup> attributes depends on the vocabulary used.

##### Example

Here, an item is talking about a particular book:

```
<dl itemscope
  itemtype="https://vocab.example.net/book"
  itemid="urn:isbn:0-330-34032-8">
  <dt>Title
  <dd itemprop="title">The Reality Dysfunction
  <dt>Author
  <dd itemprop="author">Peter F. Hamilton
  <dt>Publication date
  <dd><time itemprop="pubdate" datetime="1996-01-26">26 January 1996</time>
</dl>
```

The "https://vocab.example.net/book" vocabulary in this example would define that the [itemid](#)<sup>p794</sup> attribute takes a [urn: URL](#) pointing to the ISBN of the book.

#### 5.1.5 Selecting names when defining vocabularies §<sup>p79</sup><sub>2</sub>

*This section is non-normative.*

Using microdata means using a vocabulary. For some purposes, an ad-hoc vocabulary is adequate. For others, a vocabulary will need to be designed. Where possible, authors are encouraged to re-use existing vocabularies, as this makes content re-use easier.

When designing new vocabularies, identifiers can be created either using [URLs](#), or, for properties, as plain words (with no dots or colons). For [URLs](#), conflicts with other vocabularies can be avoided by only using identifiers that correspond to pages that the author has control over.

##### Example

For instance, if Jon and Adam both write content at example.com, at https://example.com/~jon/... and https://example.com/~adam/... respectively, then they could select identifiers of the form "https://example.com/~jon/name" and "https://example.com/~adam/name" respectively.

Properties whose names are just plain words can only be used within the context of the types for which they are intended; properties named using [URLs](#) can be reused in items of any type. If an item has no type, and is not part of another item, then if its properties have names that are just plain words, they are not intended to be globally unique, and are instead only intended for limited use. Generally speaking, authors are encouraged to use either properties with globally unique names ([URLs](#)) or ensure that their items are typed.

##### Example

Here, an item is an "https://example.org/animals#cat", and most of the properties have names that are words defined in the context of that type. There are also a few additional properties whose names come from other vocabularies.

```
<section itemscope itemtype="https://example.org/animals#cat">
  <h1 itemprop="name https://example.com/fn">Hedral</h1>
  <p itemprop="desc">Hedral is a male American domestic
```

```

shorthair, with a fluffy <span
itemprop="https://example.com/color">black</span> fur with <span
itemprop="https://example.com/color">white</span> paws and belly.</p>

</section>

```

This example has one item with the type "https://example.org/animals#cat" and the following properties:

Property	Value
name	Hedral
https://example.com/fn	Hedral
desc	Hedral is a male American domestic shorthair, with a fluffy black fur with white paws and belly.
https://example.com/color	black
https://example.com/color	white
img	.../hedral.jpeg

## 5.2 Encoding microdata §<sup>p79</sup><sub>3</sub>

### 5.2.1 The microdata model §<sup>p79</sup><sub>3</sub>

The microdata model consists of groups of name-value pairs known as [items](#)<sup>p793</sup>.

Each group is known as an [item](#)<sup>p793</sup>. Each [item](#)<sup>p793</sup> can have [item types](#)<sup>p793</sup>, a [global identifier](#)<sup>p794</sup> (if the vocabulary specified by the [item types](#)<sup>p793</sup> [support global identifiers for items](#)<sup>p794</sup>), and a list of name-value pairs. Each name in the name-value pair is known as a [property](#)<sup>p798</sup>, and each [property](#)<sup>p798</sup> has one or more [values](#)<sup>p797</sup>. Each [value](#)<sup>p797</sup> is either a string or itself a group of name-value pairs (an [item](#)<sup>p793</sup>). The names are unordered relative to each other, but if a particular name has multiple values, they do have a relative order.

### 5.2.2 Items §<sup>p79</sup><sub>3</sub>

Every [HTML element](#)<sup>p45</sup> may have an **itemscope** attribute specified. The **itemscope**<sup>p793</sup> attribute is a [boolean attribute](#)<sup>p75</sup>. ✓ MDN

An element with the **itemscope**<sup>p793</sup> attribute specified creates a new **item**, a group of name-value pairs.

Elements with an **itemscope**<sup>p793</sup> attribute may have an **itemtype** attribute specified, to give the [item types](#)<sup>p793</sup> of the [item](#)<sup>p793</sup>. ✓ MDN

The **itemtype**<sup>p793</sup> attribute, if specified, must have a value that is an [unordered set of unique space-separated tokens](#)<sup>p95</sup>, none of which are [identical to](#) another token and each of which is a [valid URL string](#) that is an [absolute URL](#), and all of which are defined to use the same vocabulary. The attribute's value must have at least one token.

The **item types** of an [item](#)<sup>p793</sup> are the tokens obtained by [splitting the element's itemtype attribute's value on ASCII whitespace](#). If the **itemtype**<sup>p793</sup> attribute is missing or parsing it in this way finds no tokens, the [item](#)<sup>p793</sup> is said to have no [item types](#)<sup>p793</sup>.

The [item types](#)<sup>p793</sup> must all be types defined in [applicable specifications](#)<sup>p73</sup> and must all be defined to use the same vocabulary.

Except if otherwise specified by that specification, the [URLs](#) given as the [item types](#)<sup>p793</sup> should not be automatically dereferenced.

#### Note

*A specification could define that its [item type](#)<sup>p793</sup> can be dereferenced to provide the user with help information, for example. In fact, vocabulary authors are encouraged to provide useful information at the given [URL](#).*

[Item types](#)<sup>p793</sup> are opaque identifiers, and user agents must not dereference unknown [item types](#)<sup>p793</sup>, or otherwise deconstruct them, in order to determine how to process [items](#)<sup>p793</sup> that use them.

The **itemtype**<sup>p793</sup> attribute must not be specified on elements that do not have an **itemscope**<sup>p793</sup> attribute specified.

An [item](#)<sup>p793</sup> is said to be a **typed item** when either it has an [item type](#)<sup>p793</sup>, or it is the [value](#)<sup>p797</sup> of a [property](#)<sup>p798</sup> of a [typed item](#)<sup>p794</sup>. The **relevant types** for a [typed item](#)<sup>p794</sup> is the [item](#)<sup>p793</sup>'s [item types](#)<sup>p793</sup>, if it has any, or else is the [relevant types](#)<sup>p794</sup> of the [item](#)<sup>p793</sup> for which it is a [property](#)<sup>p798</sup>'s [value](#)<sup>p797</sup>.

Elements with an [itemscope](#)<sup>p793</sup> attribute and an [itemtype](#)<sup>p793</sup> attribute that references a vocabulary that is defined to **support global identifiers for items** may also have an **itemid** attribute specified, to give a global identifier for the [item](#)<sup>p793</sup>, so that it can be related to other [items](#)<sup>p793</sup> on pages elsewhere on the web.

The [itemid](#)<sup>p794</sup> attribute, if specified, must have a value that is a [valid URL potentially surrounded by spaces](#)<sup>p96</sup>.

The **global identifier** of an [item](#)<sup>p793</sup> is the value of its element's [itemid](#)<sup>p794</sup> attribute, if it has one, [parsed](#)<sup>p97</sup> relative to the [node document](#) of the element on which the attribute is specified. If the [itemid](#)<sup>p794</sup> attribute is missing or if parsing it returns failure, it is said to have no [global identifier](#)<sup>p794</sup>.

The [itemid](#)<sup>p794</sup> attribute must not be specified on elements that do not have both an [itemscope](#)<sup>p793</sup> attribute and an [itemtype](#)<sup>p793</sup> attribute specified, and must not be specified on elements with an [itemscope](#)<sup>p793</sup> attribute whose [itemtype](#)<sup>p793</sup> attribute specifies a vocabulary that does not [support global identifiers for items](#)<sup>p794</sup>, as defined by that vocabulary's specification.

The exact meaning of a [global identifier](#)<sup>p794</sup> is determined by the vocabulary's specification. It is up to such specifications to define whether multiple items with the same global identifier (whether on the same page or on different pages) are allowed to exist, and what the processing rules for that vocabulary are with respect to handling the case of multiple items with the same ID.

Elements with an [itemscope](#)<sup>p793</sup> attribute may have an **itemref** attribute specified, to give a list of additional elements to crawl to find the name-value pairs of the [item](#)<sup>p793</sup>.

The [itemref](#)<sup>p794</sup> attribute, if specified, must have a value that is an [unordered set of unique space-separated tokens](#)<sup>p95</sup> none of which are [identical to](#) another token and consisting of [IDs](#) of elements in the same [tree](#).

The [itemref](#)<sup>p794</sup> attribute must not be specified on elements that do not have an [itemscope](#)<sup>p793</sup> attribute specified.

#### Note

The [itemref](#)<sup>p794</sup> attribute is not part of the microdata data model. It is merely a syntactic construct to aid authors in adding annotations to pages where the data to be annotated does not follow a convenient tree structure. For example, it allows authors to mark up data in a table so that each column defines a separate [item](#)<sup>p793</sup>, while keeping the properties in the cells.

#### Example

This example shows a simple vocabulary used to describe the products of a model railway manufacturer. The vocabulary has just five property names:

##### product-code

An integer that names the product in the manufacturer's catalog.

##### name

A brief description of the product.

##### scale

One of "HO", "1", or "Z" (potentially with leading or trailing whitespace), indicating the scale of the product.

##### digital

If present, one of "Digital", "Delta", or "Systems" (potentially with leading or trailing whitespace) indicating that the product has a digital decoder of the given type.

##### track-type

For track-specific products, one of "K", "M", "C" (potentially with leading or trailing whitespace) indicating the type of track for which the product is intended.

This vocabulary has four defined [item types](#)<sup>p793</sup>:

##### <https://md.example.com/loco>

Rolling stock with an engine

**https://md.example.com/passengers**

Passenger rolling stock

**https://md.example.com/track**

Track pieces

**https://md.example.com/lighting**

Equipment with lighting

Each [item](#)<sup>p793</sup> that uses this vocabulary can be given one or more of these types, depending on what the product is.

Thus, a locomotive might be marked up as:

```
<dl itemscope itemtype="https://md.example.com/loco
                        https://md.example.com/lighting">
  <dt>Name:
  <dd itemprop="name">Tank Locomotive (DB 80)
  <dt>Product code:
  <dd itemprop="product-code">33041
  <dt>Scale:
  <dd itemprop="scale">H0
  <dt>Digital:
  <dd itemprop="digital">Delta
</dl>
```

A turnout lantern retrofit kit might be marked up as:

```
<dl itemscope itemtype="https://md.example.com/track
                        https://md.example.com/lighting">
  <dt>Name:
  <dd itemprop="name">Turnout Lantern Kit
  <dt>Product code:
  <dd itemprop="product-code">74470
  <dt>Purpose:
  <dd>For retrofitting 2 <span itemprop="track-type">C</span> Track
    turnouts. <meta itemprop="scale" content="H0">
</dl>
```

A passenger car with no lighting might be marked up as:

```
<dl itemscope itemtype="https://md.example.com/passengers">
  <dt>Name:
  <dd itemprop="name">Express Train Passenger Car (DB Am 203)
  <dt>Product code:
  <dd itemprop="product-code">8710
  <dt>Scale:
  <dd itemprop="scale">Z
</dl>
```

Great care is necessary when creating new vocabularies. Often, a hierarchical approach to types can be taken that results in a vocabulary where each item only ever has a single type, which is generally much simpler to manage.

### 5.2.3 Names: the **itemprop** attribute <sup>p79</sup><sub>5</sub>

Every [HTML element](#)<sup>p45</sup> may have an **itemprop**<sup>p795</sup> attribute specified, if doing so [adds one or more properties](#)<sup>p798</sup> to one or more [items](#)<sup>p793</sup> (as defined below).

The **itemprop**<sup>p795</sup> attribute, if specified, must have a value that is an [unordered set of unique space-separated tokens](#)<sup>p95</sup> none of which

are [identical to](#) another token, representing the names of the name-value pairs that it adds. The attribute's value must have at least one token.

Each token must be either:

- If the item is a [typed item](#)<sup>p794</sup>: a **defined property name** allowed in this situation according to the specification that defines the [relevant types](#)<sup>p794</sup> for the item, or
- A [valid URL string](#) that is an [absolute URL](#) defined as an item property name allowed in this situation by a vocabulary specification, or
- A [valid URL string](#) that is an [absolute URL](#), used as a proprietary item property name (i.e. one used by the author for private purposes, not defined in a public specification), or
- If the item is not a [typed item](#)<sup>p794</sup>: a string that contains no U+002E FULL STOP characters (.) and no U+003A COLON characters (:), used as a proprietary item property name (i.e. one used by the author for private purposes, not defined in a public specification).

Specifications that introduce [defined property names](#)<sup>p796</sup> must ensure all such property names contain no U+002E FULL STOP characters (.), no U+003A COLON characters (:), and no [ASCII whitespace](#).

#### Note

*The rules above disallow U+003A COLON characters (:) in non-URL values because otherwise they could not be distinguished from URLs. Values with U+002E FULL STOP characters (.) are reserved for future extensions. [ASCII whitespace](#) are disallowed because otherwise the values would be parsed as multiple tokens.*

When an element with an [itemprop](#)<sup>p795</sup> attribute [adds a property](#)<sup>p798</sup> to multiple [items](#)<sup>p793</sup>, the requirement above regarding the tokens applies for each [item](#)<sup>p793</sup> individually.

The **property names** of an element are the tokens that the element's [itemprop](#)<sup>p795</sup> attribute is found to contain when its value is [split on ASCII whitespace](#), with the order preserved but with duplicates removed (leaving only the first occurrence of each name).

Within an [item](#)<sup>p793</sup>, the properties are unordered with respect to each other, except for properties with the same name, which are ordered in the order they are given by the algorithm that defines [the properties of an item](#)<sup>p798</sup>.

#### Example

In the following example, the "a" property has the values "1" and "2", *in that order*, but whether the "a" property comes before the "b" property or not is not important:

```
<div itemscope>
  <p itemprop="a">1</p>
  <p itemprop="a">2</p>
  <p itemprop="b">test</p>
</div>
```

Thus, the following is equivalent:

```
<div itemscope>
  <p itemprop="b">test</p>
  <p itemprop="a">1</p>
  <p itemprop="a">2</p>
</div>
```

As is the following:

```
<div itemscope>
  <p itemprop="a">1</p>
  <p itemprop="b">test</p>
  <p itemprop="a">2</p>
</div>
```

And the following:

```
<div id="x">
  <p itemprop="a">1</p>
</div>
<div itemscope itemref="x">
  <p itemprop="b">test</p>
  <p itemprop="a">2</p>
</div>
```

## 5.2.4 Values <sup>§<sup>p79</sup></sup><sub>7</sub>

The **property value** of a name-value pair added by an element with an `itempropp795` attribute is as given for the first matching case in the following list:

↪ **If the element also has an `itemscopep793` attribute**

The value is the `itemp793` created by the element.

↪ **If the element is a `metap189` element**

The value is the value of the element's `contentp198` attribute, if any, or the empty string if there is no such attribute.

↪ **If the element is an `audiop410`, `embedp399`, `iframep390`, `imgp346`, `sourcep343`, `trackp411`, or `videop406` element**

The value is the result of `encoding-parsing-and-serializing a URLp97` given the element's `src` attribute's value, relative to the element's `node document`, at the time the attribute is set, or the empty string if there is no such attribute or the result is failure.

↪ **If the element is an `ap257`, `areap471`, or `linkp177` element**

The value is the result of `encoding-parsing-and-serializing a URLp97` given the element's `href` attribute's value, relative to the element's `node document`, at the time the attribute is set, or the empty string if there is no such attribute or the result is failure.

↪ **If the element is an `objectp402` element**

The value is the result of `encoding-parsing-and-serializing a URLp97` given the element's `data` attribute's value, relative to the element's `node document`, at the time the attribute is set, or the empty string if there is no such attribute or the result is failure.

↪ **If the element is a `datap278` element**

The value is the value of the element's `valuep279` attribute, if it has one, or the empty string otherwise.

↪ **If the element is a `meterp589` element**

The value is the value of the element's `valuep590` attribute, if it has one, or the empty string otherwise.

↪ **If the element is a `timep279` element**

The value is the element's `datetime valuep280`.

↪ **Otherwise**

The value is the element's `descendant text content`.

The **URL property elements** are the `ap257`, `areap471`, `audiop410`, `embedp399`, `iframep390`, `imgp346`, `linkp177`, `objectp402`, `sourcep343`, `trackp411`, and `videop406` elements.

If a property's `valuep797`, as defined by the property's definition, is an **absolute URL**, the property must be specified using a **URL property element<sup>p797</sup>**.

### Note

*These requirements do not apply just because a property value happens to match the syntax for a URL. They only apply if the property is explicitly defined as taking such a value.*

## Example

For example, a book about the first moon landing could be called "mission:moon". A "title" property from a vocabulary that defines a title as being a string would not expect the title to be given in an [a<sup>p257</sup>](#) element, even though it looks like a [URL](#). On the other hand, if there was a (rather narrowly scoped!) vocabulary for "books whose titles look like URLs" which had a "title" property defined to take a URL, then the property *would* expect the title to be given in an [a<sup>p257</sup>](#) element (or one of the other [URL property elements<sup>p797</sup>](#)), because of the requirement above.

### 5.2.5 Associating names with items <sup>§<sup>p79</sup></sup><sub>8</sub>

To find **the properties of an item** defined by the element *root*, the user agent must run the following steps. These steps are also used to flag [microdata errors<sup>p798</sup>](#).

1. Let *results*, *memory*, and *pending* be empty lists of elements.
2. Add the element *root* to *memory*.
3. Add the child elements of *root*, if any, to *pending*.
4. If *root* has an [itemref<sup>p794</sup>](#) attribute, [split the value of that itemref attribute on ASCII whitespace](#). For each resulting token *ID*, if there is an element in the [tree](#) of *root* with the [ID](#) *ID*, then add the first such element to *pending*.
5. While *pending* is not empty:
  1. Remove an element from *pending* and let *current* be that element.
  2. If *current* is already in *memory*, there is a [microdata error<sup>p798</sup>](#); [continue](#).
  3. Add *current* to *memory*.
  4. If *current* does not have an [itemscope<sup>p793</sup>](#) attribute, then: add all the child elements of *current* to *pending*.
  5. If *current* has an [itemprop<sup>p795</sup>](#) attribute specified and has one or more [property names<sup>p796</sup>](#), then add *current* to *results*.
6. Sort *results* in [tree order](#).
7. Return *results*.

A document must not contain any [items<sup>p793</sup>](#) for which the algorithm to find [the properties of an item<sup>p798</sup>](#) finds any **microdata errors**.

An [item<sup>p793</sup>](#) is a **top-level microdata item** if its element does not have an [itemprop<sup>p795</sup>](#) attribute.

All [itemref<sup>p794</sup>](#) attributes in a [Document<sup>p130</sup>](#) must be such that there are no cycles in the graph formed from representing each [item<sup>p793</sup>](#) in the [Document<sup>p130</sup>](#) as a node in the graph and each [property<sup>p798</sup>](#) of an item whose [value<sup>p797</sup>](#) is another item as an edge in the graph connecting those two items.

A document must not contain any elements that have an [itemprop<sup>p795</sup>](#) attribute that would not be found to be a property of any of the [items<sup>p793</sup>](#) in that document were their [properties<sup>p798</sup>](#) all to be determined.

## Example

In this example, a single license statement is applied to two works, using [itemref<sup>p794</sup>](#) from the items representing the works:

```
<!DOCTYPE HTML>
<html lang="en">
  <head>
    <title>Photo gallery</title>
  </head>
  <body>
    <h1>My photos</h1>
    <figure itemscope itemtype="http://n.whatwg.org/work" itemref="licenses">
      
      <figcaption itemprop="title">The house I found.</figcaption>
    </figure>
  </body>
</html>
```

```

</figure>
<figure itemscope itemtype="http://n.whatwg.org/work" itemref="licenses">
  
  <figcaption itemprop="title">The mailbox.</figcaption>
</figure>
<footer>
  <p id="licenses">All images licensed under the <a itemprop="license"
href="http://www.opensource.org/licenses/mit-license.php">MIT
license</a>.</p>
</footer>
</body>
</html>

```

The above results in two items with the type "http://n.whatwg.org/work", one with:

```

work
  images/house.jpeg
title
  The house I found.
license
  http://www.opensource.org/licenses/mit-license.php

```

...and one with:

```

work
  images/mailbox.jpeg
title
  The mailbox.
license
  http://www.opensource.org/licenses/mit-license.php

```

### 5.2.6 Microdata and other namespaces §<sup>p79</sup><sub>9</sub>

Currently, the [itemscope<sup>p793</sup>](#), [itemprop<sup>p795</sup>](#), and other microdata attributes are only defined for [HTML elements<sup>p45</sup>](#). This means that attributes with the literal names "itemscope", "itemprop", etc, do not cause microdata processing to occur on elements in other namespaces, such as SVG.

#### Example

Thus, in the following example there is only one item, not two.

```

<p itemscope></p> <!-- this is an item (with no properties and no type) -->
<svg itemscope></svg> <!-- this is not, it's just an SVG svg element with an invalid unknown
attribute -->

```

## 5.3 Sample microdata vocabularies §<sup>p79</sup><sub>9</sub>

The vocabularies in this section are primarily intended to demonstrate how a vocabulary is specified, though they are also usable in their own right.

### 5.3.1 vCard § p800

An item with the [item type](#)<sup>p793</sup> <http://microformats.org/profile/hcard> represents a person's or organization's contact information.

This vocabulary does not [support global identifiers for items](#)<sup>p794</sup>.

The following are the type's [defined property names](#)<sup>p796</sup>. They are based on the vocabulary defined in *vCard Format Specification* (vCard) and its extensions, where more information on how to interpret the values can be found. [\[RFC6350\]](#)<sup>p1481</sup>

#### kind

Describes what kind of contact the item represents.

The [value](#)<sup>p797</sup> must be text that is [identical to](#) one of the [kind strings](#)<sup>p807</sup>.

A single property with the name [kind](#)<sup>p800</sup> may be present within each [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcard><sup>p800</sup>.

#### fn

Gives the formatted text corresponding to the name of the person or organization.

The [value](#)<sup>p797</sup> must be text.

Exactly one property with the name [fn](#)<sup>p800</sup> must be present within each [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcard><sup>p800</sup>.

#### n

Gives the structured name of the person or organization.

The [value](#)<sup>p797</sup> must be an [item](#)<sup>p793</sup> with zero or more of each of the [family-name](#)<sup>p800</sup>, [given-name](#)<sup>p800</sup>, [additional-name](#)<sup>p800</sup>, [honorific-prefix](#)<sup>p800</sup>, and [honorific-suffix](#)<sup>p801</sup> properties.

Exactly one property with the name [n](#)<sup>p800</sup> must be present within each [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcard><sup>p800</sup>.

#### family-name (inside [n](#)<sup>p800</sup>)

Gives the family name of the person, or the full name of the organization.

The [value](#)<sup>p797</sup> must be text.

Any number of properties with the name [family-name](#)<sup>p800</sup> may be present within the [item](#)<sup>p793</sup> that forms the [value](#)<sup>p797</sup> of the [n](#)<sup>p800</sup> property of an [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcard><sup>p800</sup>.

#### given-name (inside [n](#)<sup>p800</sup>)

Gives the given-name of the person.

The [value](#)<sup>p797</sup> must be text.

Any number of properties with the name [given-name](#)<sup>p800</sup> may be present within the [item](#)<sup>p793</sup> that forms the [value](#)<sup>p797</sup> of the [n](#)<sup>p800</sup> property of an [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcard><sup>p800</sup>.

#### additional-name (inside [n](#)<sup>p800</sup>)

Gives the any additional names of the person.

The [value](#)<sup>p797</sup> must be text.

Any number of properties with the name [additional-name](#)<sup>p800</sup> may be present within the [item](#)<sup>p793</sup> that forms the [value](#)<sup>p797</sup> of the [n](#)<sup>p800</sup> property of an [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcard><sup>p800</sup>.

#### honorific-prefix (inside [n](#)<sup>p800</sup>)

Gives the honorific prefix of the person.

The [value](#)<sup>p797</sup> must be text.

Any number of properties with the name [honorific-prefix](#)<sup>p800</sup> may be present within the [item](#)<sup>p793</sup> that forms the [value](#)<sup>p797</sup> of the

**n**<sup>p800</sup> property of an **item**<sup>p793</sup> with the type <http://microformats.org/profile/hcard><sup>p800</sup>.

### **honorific-suffix (inside n<sup>p800</sup>)**

Gives the honorific suffix of the person.

The **value**<sup>p797</sup> must be text.

Any number of properties with the name **honorific-suffix**<sup>p801</sup> may be present within the **item**<sup>p793</sup> that forms the **value**<sup>p797</sup> of the **n**<sup>p800</sup> property of an **item**<sup>p793</sup> with the type <http://microformats.org/profile/hcard><sup>p800</sup>.

### **nickname**

Gives the nickname of the person or organization.

#### **Note**

*The nickname is the descriptive name given instead of or in addition to the one belonging to a person, place, or thing. It can also be used to specify a familiar form of a proper name specified by the **fn**<sup>p800</sup> or **n**<sup>p800</sup> properties.*

The **value**<sup>p797</sup> must be text.

Any number of properties with the name **nickname**<sup>p801</sup> may be present within each **item**<sup>p793</sup> with the type <http://microformats.org/profile/hcard><sup>p800</sup>.

### **photo**

Gives a photograph of the person or organization.

The **value**<sup>p797</sup> must be an [absolute URL](#).

Any number of properties with the name **photo**<sup>p801</sup> may be present within each **item**<sup>p793</sup> with the type <http://microformats.org/profile/hcard><sup>p800</sup>.

### **bday**

Gives the birth date of the person or organization.

The **value**<sup>p797</sup> must be a [valid date string](#)<sup>p83</sup>.

A single property with the name **bday**<sup>p801</sup> may be present within each **item**<sup>p793</sup> with the type <http://microformats.org/profile/hcard><sup>p800</sup>.

### **anniversary**

Gives the birth date of the person or organization.

The **value**<sup>p797</sup> must be a [valid date string](#)<sup>p83</sup>.

A single property with the name **anniversary**<sup>p801</sup> may be present within each **item**<sup>p793</sup> with the type <http://microformats.org/profile/hcard><sup>p800</sup>.

### **sex**

Gives the biological sex of the person.

The **value**<sup>p797</sup> must be one of F, meaning "female", M, meaning "male", N, meaning "none or not applicable", O, meaning "other", or U, meaning "unknown".

A single property with the name **sex**<sup>p801</sup> may be present within each **item**<sup>p793</sup> with the type <http://microformats.org/profile/hcard><sup>p800</sup>.

### **gender-identity**

Gives the gender identity of the person.

The **value**<sup>p797</sup> must be text.

A single property with the name **gender-identity**<sup>p801</sup> may be present within each **item**<sup>p793</sup> with the type <http://microformats.org/profile/hcard><sup>p800</sup>.

## adr

Gives the delivery address of the person or organization.

The [value](#)<sup>p797</sup> must be an [item](#)<sup>p793</sup> with zero or more [type](#)<sup>p802</sup>, [post-office-box](#)<sup>p802</sup>, [extended-address](#)<sup>p802</sup>, and [street-address](#)<sup>p802</sup> properties, and optionally a [locality](#)<sup>p802</sup> property, optionally a [region](#)<sup>p802</sup> property, optionally a [postal-code](#)<sup>p803</sup> property, and optionally a [country-name](#)<sup>p803</sup> property.

If no [type](#)<sup>p802</sup> properties are present within an [item](#)<sup>p793</sup> that forms the [value](#)<sup>p797</sup> of an [adr](#)<sup>p802</sup> property of an [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcard><sup>p800</sup>, then the [address type string](#)<sup>p807</sup> [work](#)<sup>p807</sup> is implied.

Any number of properties with the name [adr](#)<sup>p802</sup> may be present within each [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcard><sup>p800</sup>.

### type (inside [adr](#)<sup>p802</sup>)

Gives the type of delivery address.

The [value](#)<sup>p797</sup> must be text that is [identical to](#) one of the [address type strings](#)<sup>p807</sup>.

Any number of properties with the name [type](#)<sup>p802</sup> may be present within the [item](#)<sup>p793</sup> that forms the [value](#)<sup>p797</sup> of an [adr](#)<sup>p802</sup> property of an [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcard><sup>p800</sup>, but within each such [adr](#)<sup>p802</sup> property [item](#)<sup>p793</sup> there must only be one [type](#)<sup>p802</sup> property per distinct value.

### post-office-box (inside [adr](#)<sup>p802</sup>)

Gives the post office box component of the delivery address of the person or organization.

The [value](#)<sup>p797</sup> must be text.

Any number of properties with the name [post-office-box](#)<sup>p802</sup> may be present within the [item](#)<sup>p793</sup> that forms the [value](#)<sup>p797</sup> of an [adr](#)<sup>p802</sup> property of an [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcard><sup>p800</sup>.

#### Note

*vCard urges authors not to use this field.*

### extended-address (inside [adr](#)<sup>p802</sup>)

Gives an additional component of the delivery address of the person or organization.

The [value](#)<sup>p797</sup> must be text.

Any number of properties with the name [extended-address](#)<sup>p802</sup> may be present within the [item](#)<sup>p793</sup> that forms the [value](#)<sup>p797</sup> of an [adr](#)<sup>p802</sup> property of an [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcard><sup>p800</sup>.

#### Note

*vCard urges authors not to use this field.*

### street-address (inside [adr](#)<sup>p802</sup>)

Gives the street address component of the delivery address of the person or organization.

The [value](#)<sup>p797</sup> must be text.

Any number of properties with the name [street-address](#)<sup>p802</sup> may be present within the [item](#)<sup>p793</sup> that forms the [value](#)<sup>p797</sup> of an [adr](#)<sup>p802</sup> property of an [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcard><sup>p800</sup>.

### locality (inside [adr](#)<sup>p802</sup>)

Gives the locality component (e.g. city) of the delivery address of the person or organization.

The [value](#)<sup>p797</sup> must be text.

A single property with the name [locality](#)<sup>p802</sup> may be present within the [item](#)<sup>p793</sup> that forms the [value](#)<sup>p797</sup> of an [adr](#)<sup>p802</sup> property of an [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcard><sup>p800</sup>.

### region (inside [adr](#)<sup>p802</sup>)

Gives the region component (e.g. state or province) of the delivery address of the person or organization.

The [value<sup>p797</sup>](#) must be text.

A single property with the name [region<sup>p802</sup>](#) may be present within the [item<sup>p793</sup>](#) that forms the [value<sup>p797</sup>](#) of an [adr<sup>p802</sup>](#) property of an [item<sup>p793</sup>](#) with the type [http://microformats.org/profile/hcard<sup>p800</sup>](http://microformats.org/profile/hcard).

#### **postal-code (inside [adr<sup>p802</sup>](#))**

Gives the postal code component of the delivery address of the person or organization.

The [value<sup>p797</sup>](#) must be text.

A single property with the name [postal-code<sup>p803</sup>](#) may be present within the [item<sup>p793</sup>](#) that forms the [value<sup>p797</sup>](#) of an [adr<sup>p802</sup>](#) property of an [item<sup>p793</sup>](#) with the type [http://microformats.org/profile/hcard<sup>p800</sup>](http://microformats.org/profile/hcard).

#### **country-name (inside [adr<sup>p802</sup>](#))**

Gives the country name component of the delivery address of the person or organization.

The [value<sup>p797</sup>](#) must be text.

A single property with the name [country-name<sup>p803</sup>](#) may be present within the [item<sup>p793</sup>](#) that forms the [value<sup>p797</sup>](#) of an [adr<sup>p802</sup>](#) property of an [item<sup>p793</sup>](#) with the type [http://microformats.org/profile/hcard<sup>p800</sup>](http://microformats.org/profile/hcard).

#### **tel**

Gives the telephone number of the person or organization.

The [value<sup>p797</sup>](#) must be either text that can be interpreted as a telephone number as defined in the CCITT specifications E.163 and X.121, or an [item<sup>p793</sup>](#) with zero or more [type<sup>p803</sup>](#) properties and exactly one [value<sup>p803</sup>](#) property. [\[E163\]<sup>p1478</sup>](#) [\[X121\]<sup>p1484</sup>](#)

If no [type<sup>p803</sup>](#) properties are present within an [item<sup>p793</sup>](#) that forms the [value<sup>p797</sup>](#) of a [tel<sup>p803</sup>](#) property of an [item<sup>p793</sup>](#) with the type [http://microformats.org/profile/hcard<sup>p800</sup>](http://microformats.org/profile/hcard), or if the [value<sup>p797</sup>](#) of such a [tel<sup>p803</sup>](#) property is text, then the [telephone type string<sup>p807</sup>](#) [voice<sup>p807</sup>](#) is implied.

Any number of properties with the name [tel<sup>p803</sup>](#) may be present within each [item<sup>p793</sup>](#) with the type [http://microformats.org/profile/hcard<sup>p800</sup>](http://microformats.org/profile/hcard).

#### **type (inside [tel<sup>p803</sup>](#))**

Gives the type of telephone number.

The [value<sup>p797</sup>](#) must be text that is [identical to](#) one of the [telephone type strings<sup>p807</sup>](#).

Any number of properties with the name [type<sup>p803</sup>](#) may be present within the [item<sup>p793</sup>](#) that forms the [value<sup>p797</sup>](#) of a [tel<sup>p803</sup>](#) property of an [item<sup>p793</sup>](#) with the type [http://microformats.org/profile/hcard<sup>p800</sup>](http://microformats.org/profile/hcard), but within each such [tel<sup>p803</sup>](#) property [item<sup>p793</sup>](#) there must only be one [type<sup>p803</sup>](#) property per distinct value.

#### **value (inside [tel<sup>p803</sup>](#))**

Gives the actual telephone number of the person or organization.

The [value<sup>p797</sup>](#) must be text that can be interpreted as a telephone number as defined in the CCITT specifications E.163 and X.121. [\[E163\]<sup>p1478</sup>](#) [\[X121\]<sup>p1484</sup>](#)

Exactly one property with the name [value<sup>p803</sup>](#) must be present within the [item<sup>p793</sup>](#) that forms the [value<sup>p797</sup>](#) of a [tel<sup>p803</sup>](#) property of an [item<sup>p793</sup>](#) with the type [http://microformats.org/profile/hcard<sup>p800</sup>](http://microformats.org/profile/hcard).

#### **email**

Gives the email address of the person or organization.

The [value<sup>p797</sup>](#) must be text.

Any number of properties with the name [email<sup>p803</sup>](#) may be present within each [item<sup>p793</sup>](#) with the type [http://microformats.org/profile/hcard<sup>p800</sup>](http://microformats.org/profile/hcard).

#### **impp**

Gives a [URL](#) for instant messaging and presence protocol communications with the person or organization.

The [value<sup>p797</sup>](#) must be an [absolute URL](#).

Any number of properties with the name [impp<sup>p803</sup>](#) may be present within each [item<sup>p793</sup>](#) with the type <http://microformats.org/profile/hcard<sup>p800</sup>>.

## lang

Gives a language understood by the person or organization.

The [value<sup>p797</sup>](#) must be a valid BCP 47 language tag. [\[BCP47\]<sup>p1475</sup>](#)

Any number of properties with the name [lang<sup>p804</sup>](#) may be present within each [item<sup>p793</sup>](#) with the type <http://microformats.org/profile/hcard<sup>p800</sup>>.

## tz

Gives the time zone of the person or organization.

The [value<sup>p797</sup>](#) must be text and must match the following syntax:

1. Either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
2. A [valid non-negative integer<sup>p77</sup>](#) that is exactly two digits long and that represents a number in the range 00..23.
3. A U+003A COLON character (:).
4. A [valid non-negative integer<sup>p77</sup>](#) that is exactly two digits long and that represents a number in the range 00..59.

Any number of properties with the name [tz<sup>p804</sup>](#) may be present within each [item<sup>p793</sup>](#) with the type <http://microformats.org/profile/hcard<sup>p800</sup>>.

## geo

Gives the geographical position of the person or organization.

The [value<sup>p797</sup>](#) must be text and must match the following syntax:

1. Optionally, either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
2. One or more [ASCII digits](#).
3. Optionally\*, a U+002E FULL STOP character (.) followed by one or more [ASCII digits](#).
4. A U+003B SEMICOLON character (;).
5. Optionally, either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
6. One or more [ASCII digits](#).
7. Optionally\*, a U+002E FULL STOP character (.) followed by one or more [ASCII digits](#).

The optional components marked with an asterisk (\*) should be included, and should have six digits each.

### Note

*The value specifies latitude and longitude, in that order (i.e., "LAT LON" ordering), in decimal degrees. The longitude represents the location east and west of the prime meridian as a positive or negative real number, respectively. The latitude represents the location north and south of the equator as a positive or negative real number, respectively.*

Any number of properties with the name [geo<sup>p804</sup>](#) may be present within each [item<sup>p793</sup>](#) with the type <http://microformats.org/profile/hcard<sup>p800</sup>>.

## title

Gives the job title, functional position or function of the person or organization.

The [value<sup>p797</sup>](#) must be text.

Any number of properties with the name [title<sup>p804</sup>](#) may be present within each [item<sup>p793</sup>](#) with the type <http://microformats.org/profile/hcard<sup>p800</sup>>.

## role

Gives the role, occupation, or business category of the person or organization.

The [value<sup>p797</sup>](#) must be text.

Any number of properties with the name [role<sup>p804</sup>](#) may be present within each [item<sup>p793</sup>](#) with the type <http://microformats.org/profile/hcard<sup>p800</sup>>.

## logo

Gives the logo of the person or organization.

The [value<sup>p797</sup>](#) must be an [absolute URL](#).

Any number of properties with the name [logo<sup>p805</sup>](#) may be present within each [item<sup>p793</sup>](#) with the type <http://microformats.org/profile/hcard<sup>p800</sup>>.

## agent

Gives the contact information of another person who will act on behalf of the person or organization.

The [value<sup>p797</sup>](#) must be either an [item<sup>p793</sup>](#) with the type <http://microformats.org/profile/hcard<sup>p800</sup>>, or an [absolute URL](#), or text.

Any number of properties with the name [agent<sup>p805</sup>](#) may be present within each [item<sup>p793</sup>](#) with the type <http://microformats.org/profile/hcard<sup>p800</sup>>.

## org

Gives the name and units of the organization.

The [value<sup>p797</sup>](#) must be either text or an [item<sup>p793</sup>](#) with one [organization-name<sup>p805</sup>](#) property and zero or more [organization-unit<sup>p805</sup>](#) properties.

Any number of properties with the name [org<sup>p805</sup>](#) may be present within each [item<sup>p793</sup>](#) with the type <http://microformats.org/profile/hcard<sup>p800</sup>>.

### organization-name (inside [org<sup>p805</sup>](#))

Gives the name of the organization.

The [value<sup>p797</sup>](#) must be text.

Exactly one property with the name [organization-name<sup>p805</sup>](#) must be present within the [item<sup>p793</sup>](#) that forms the [value<sup>p797</sup>](#) of an [org<sup>p805</sup>](#) property of an [item<sup>p793</sup>](#) with the type <http://microformats.org/profile/hcard<sup>p800</sup>>.

### organization-unit (inside [org<sup>p805</sup>](#))

Gives the name of the organization unit.

The [value<sup>p797</sup>](#) must be text.

Any number of properties with the name [organization-unit<sup>p805</sup>](#) may be present within the [item<sup>p793</sup>](#) that forms the [value<sup>p797</sup>](#) of the [org<sup>p805</sup>](#) property of an [item<sup>p793</sup>](#) with the type <http://microformats.org/profile/hcard<sup>p800</sup>>.

## member

Gives a [URL](#) that represents a member of the group.

The [value<sup>p797</sup>](#) must be an [absolute URL](#).

Any number of properties with the name [member<sup>p805</sup>](#) may be present within each [item<sup>p793</sup>](#) with the type <http://microformats.org/profile/hcard<sup>p800</sup>> if the [item<sup>p793</sup>](#) also has a property with the name [kind<sup>p800</sup>](#) whose value is ["group<sup>p807</sup>"](#).

## related

Gives a relationship to another entity.

The [value<sup>p797</sup>](#) must be an [item<sup>p793</sup>](#) with one [url<sup>p805</sup>](#) property and one [rel<sup>p806</sup>](#) properties.

Any number of properties with the name [related<sup>p805</sup>](#) may be present within each [item<sup>p793</sup>](#) with the type <http://microformats.org/profile/hcard<sup>p800</sup>>.

### url (inside [related<sup>p805</sup>](#))

Gives the [URL](#) for the related entity.

The [value<sup>p797</sup>](#) must be an [absolute URL](#).

Exactly one property with the name [url<sup>p805</sup>](#) must be present within the [item<sup>p793</sup>](#) that forms the [value<sup>p797</sup>](#) of a [related<sup>p805</sup>](#) property of an [item<sup>p793</sup>](#) with the type [http://microformats.org/profile/hcard<sup>p800</sup>](#).

### **rel (inside [related<sup>p805</sup>](#))**

Gives the relationship between the entity and the related entity.

The [value<sup>p797</sup>](#) must be text that is [identical to](#) one of the [relationship strings<sup>p807</sup>](#).

Exactly one property with the name [rel<sup>p806</sup>](#) must be present within the [item<sup>p793</sup>](#) that forms the [value<sup>p797</sup>](#) of a [related<sup>p805</sup>](#) property of an [item<sup>p793</sup>](#) with the type [http://microformats.org/profile/hcard<sup>p800</sup>](#).

### **categories**

Gives the name of a category or tag that the person or organization could be classified as.

The [value<sup>p797</sup>](#) must be text.

Any number of properties with the name [categories<sup>p806</sup>](#) may be present within each [item<sup>p793</sup>](#) with the type [http://microformats.org/profile/hcard<sup>p800</sup>](#).

### **note**

Gives supplemental information or a comment about the person or organization.

The [value<sup>p797</sup>](#) must be text.

Any number of properties with the name [note<sup>p806</sup>](#) may be present within each [item<sup>p793</sup>](#) with the type [http://microformats.org/profile/hcard<sup>p800</sup>](#).

### **rev**

Gives the revision date and time of the contact information.

The [value<sup>p797</sup>](#) must be text that is a [valid global date and time string<sup>p87</sup>](#).

### **Note**

*The value distinguishes the current revision of the information for other renditions of the information.*

Any number of properties with the name [rev<sup>p806</sup>](#) may be present within each [item<sup>p793</sup>](#) with the type [http://microformats.org/profile/hcard<sup>p800</sup>](#).

### **sound**

Gives a sound file relating to the person or organization.

The [value<sup>p797</sup>](#) must be an [absolute URL](#).

Any number of properties with the name [sound<sup>p806</sup>](#) may be present within each [item<sup>p793</sup>](#) with the type [http://microformats.org/profile/hcard<sup>p800</sup>](#).

### **uid**

Gives a globally unique identifier corresponding to the person or organization.

The [value<sup>p797</sup>](#) must be text.

A single property with the name [uid<sup>p806</sup>](#) may be present within each [item<sup>p793</sup>](#) with the type [http://microformats.org/profile/hcard<sup>p800</sup>](#).

### **url**

Gives a [URL](#) relating to the person or organization.

The [value<sup>p797</sup>](#) must be an [absolute URL](#).

Any number of properties with the name [url<sup>p806</sup>](#) may be present within each [item<sup>p793</sup>](#) with the type [http://microformats.org/profile/hcard<sup>p800</sup>](#).

The **kind strings** are:

**individual**

Indicates a single entity (e.g. a person).

**group**

Indicates multiple entities (e.g. a mailing list).

**org**

Indicates a single entity that is not a person (e.g. a company).

**location**

Indicates a geographical place (e.g. an office building).

The **address type strings** are:

**home**

Indicates a delivery address for a residence.

**work**

Indicates a delivery address for a place of work.

The **telephone type strings** are:

**home**

Indicates a residential number.

**work**

Indicates a telephone number for a place of work.

**text**

Indicates that the telephone number supports text messages (SMS).

**voice**

Indicates a voice telephone number.

**fax**

Indicates a facsimile telephone number.

**cell**

Indicates a cellular telephone number.

**video**

Indicates a video conferencing telephone number.

**pager**

Indicates a paging device telephone number.

**textphone**

Indicates a telecommunication device for people with hearing or speech difficulties.

The **relationship strings** are:

**emergency**

An emergency contact.

**agent**

Another entity that acts on behalf of this entity.

**contact**  
**acquaintance**  
**friend**  
**met**  
**worker**  
**colleague**  
**resident**  
**neighbor**  
**child**  
**parent**  
**sibling**  
**spouse**  
**kin**  
**muse**  
**crush**  
**date**  
**sweetheart**  
**me**

Has the meaning defined in XFN. [\[XFN\]<sup>p1484</sup>](#)

#### 5.3.1.1 Conversion to vCard <sup>p800</sup>

Given a list of nodes *nodes* in a [Document<sup>p130</sup>](#), a user agent must run the following algorithm to **extract any vCard data represented by those nodes** (only the first vCard is returned):

1. If none of the nodes in *nodes* are [items<sup>p793</sup>](#) with the [item type<sup>p793</sup>](#) [<sup>p800</sup>http://microformats.org/profile/hcard](http://microformats.org/profile/hcard), then there is no vCard. Abort the algorithm, returning nothing.
2. Let *node* be the first node in *nodes* that is an [item<sup>p793</sup>](#) with the [item type<sup>p793</sup>](#) [<sup>p800</sup>http://microformats.org/profile/hcard](http://microformats.org/profile/hcard).
3. Let *output* be an empty string.
4. [Add a vCard line<sup>p810</sup>](#) with the type "BEGIN" and the value "VCARD" to *output*.
5. [Add a vCard line<sup>p810</sup>](#) with the type "PROFILE" and the value "VCARD" to *output*.
6. [Add a vCard line<sup>p810</sup>](#) with the type "VERSION" and the value "4.0" to *output*.
7. [Add a vCard line<sup>p810</sup>](#) with the type "SOURCE" and the result of [escaping the vCard text string<sup>p811</sup>](#) that is the document's [URL](#) as the value to *output*.
8. If [the title element<sup>p135</sup>](#) is not null, [add a vCard line<sup>p810</sup>](#) with the type "NAME" and with the result of [escaping the vCard text string<sup>p811</sup>](#) obtained from [the title element<sup>p135</sup>](#)'s [descendant text content](#) as the value to *output*.
9. Let *sex* be the empty string.
10. Let *gender-identity* be the empty string.
11. For each element *element* that is [a property of the item<sup>p798</sup>](#) node: for each name *name* in *element*'s [property names<sup>p796</sup>](#), run the following substeps:
  1. Let *parameters* be an empty set of name-value pairs.
  2. Run the appropriate set of substeps from the following list. The steps will set a variable *value*, which is used in the next step.

**If the property's [value<sup>p797</sup>](#) is an [item<sup>p793</sup>](#) *subitem* and *name* is [n<sup>p800</sup>](#)**

1. Let *value* be the empty string.
2. Append to *value* the result of [collecting the first vCard subproperty<sup>p811</sup>](#) named [family-name<sup>p800</sup>](#) in *subitem*.

3. Append a U+003B SEMICOLON character (;) to *value*.
4. Append to *value* the result of [collecting the first vCard subproperty<sup>p811</sup>](#) named [given-name<sup>p800</sup>](#) in *subitem*.
5. Append a U+003B SEMICOLON character (;) to *value*.
6. Append to *value* the result of [collecting the first vCard subproperty<sup>p811</sup>](#) named [additional-name<sup>p800</sup>](#) in *subitem*.
7. Append a U+003B SEMICOLON character (;) to *value*.
8. Append to *value* the result of [collecting the first vCard subproperty<sup>p811</sup>](#) named [honorific-prefix<sup>p800</sup>](#) in *subitem*.
9. Append a U+003B SEMICOLON character (;) to *value*.
10. Append to *value* the result of [collecting the first vCard subproperty<sup>p811</sup>](#) named [honorific-suffix<sup>p801</sup>](#) in *subitem*.

**If the property's [value<sup>p797</sup>](#) is an [item<sup>p793</sup>](#) *subitem* and *name* is [adr<sup>p802</sup>](#)**

1. Let *value* be the empty string.
2. Append to *value* the result of [collecting vCard subproperties<sup>p811</sup>](#) named [post-office-box<sup>p802</sup>](#) in *subitem*.
3. Append a U+003B SEMICOLON character (;) to *value*.
4. Append to *value* the result of [collecting vCard subproperties<sup>p811</sup>](#) named [extended-address<sup>p802</sup>](#) in *subitem*.
5. Append a U+003B SEMICOLON character (;) to *value*.
6. Append to *value* the result of [collecting vCard subproperties<sup>p811</sup>](#) named [street-address<sup>p802</sup>](#) in *subitem*.
7. Append a U+003B SEMICOLON character (;) to *value*.
8. Append to *value* the result of [collecting the first vCard subproperty<sup>p811</sup>](#) named [locality<sup>p802</sup>](#) in *subitem*.
9. Append a U+003B SEMICOLON character (;) to *value*.
10. Append to *value* the result of [collecting the first vCard subproperty<sup>p811</sup>](#) named [region<sup>p802</sup>](#) in *subitem*.
11. Append a U+003B SEMICOLON character (;) to *value*.
12. Append to *value* the result of [collecting the first vCard subproperty<sup>p811</sup>](#) named [postal-code<sup>p803</sup>](#) in *subitem*.
13. Append a U+003B SEMICOLON character (;) to *value*.
14. Append to *value* the result of [collecting the first vCard subproperty<sup>p811</sup>](#) named [country-name<sup>p803</sup>](#) in *subitem*.
15. If there is a property named [type<sup>p802</sup>](#) in *subitem*, and the first such property has a [value<sup>p797</sup>](#) that is not an [item<sup>p793</sup>](#) and whose value consists only of [ASCII alphanumerics](#), then add a parameter named "TYPE" whose value is the [value<sup>p797</sup>](#) of that property to *parameters*.

**If the property's [value<sup>p797</sup>](#) is an [item<sup>p793</sup>](#) *subitem* and *name* is [org<sup>p805</sup>](#)**

1. Let *value* be the empty string.
2. Append to *value* the result of [collecting the first vCard subproperty<sup>p811</sup>](#) named [organization-name<sup>p805</sup>](#) in *subitem*.
3. For each property named [organization-unit<sup>p805</sup>](#) in *subitem*, run the following steps:
  1. If the [value<sup>p797</sup>](#) of the property is an [item<sup>p793</sup>](#), then skip this property.

2. Append a U+003B SEMICOLON character (;) to *value*.
3. Append the result of [escaping the vCard text string](#)<sup>p811</sup> given by the [value](#)<sup>p797</sup> of the property to *value*.

**If the property's [value](#)<sup>p797</sup> is an [item](#)<sup>p793</sup> *subitem* with the [item type](#)<sup>p793</sup> <http://microformats.org/profile/hcard><sup>p800</sup> and [name](#) is [related](#)<sup>p805</sup>**

1. Let *value* be the empty string.
2. If there is a property named [url](#)<sup>p805</sup> in *subitem*, and its element is a [URL property element](#)<sup>p797</sup>, then append the result of [escaping the vCard text string](#)<sup>p811</sup> given by the [value](#)<sup>p797</sup> of the first such property to *value*, and add a parameter with the name "VALUE" and the value "URI" to *parameters*.
3. If there is a property named [rel](#)<sup>p806</sup> in *subitem*, and the first such property has a [value](#)<sup>p797</sup> that is not an [item](#)<sup>p793</sup> and whose value consists only of [ASCII alphanumerics](#), then add a parameter named "RELATION" whose value is the [value](#)<sup>p797</sup> of that property to *parameters*.

**If the property's [value](#)<sup>p797</sup> is an [item](#)<sup>p793</sup> and [name](#) is none of the above**

1. Let *value* be the result of [collecting the first vCard subproperty](#)<sup>p811</sup> named *value* in *subitem*.
2. If there is a property named *type* in *subitem*, and the first such property has a [value](#)<sup>p797</sup> that is not an [item](#)<sup>p793</sup> and whose value consists only of [ASCII alphanumerics](#), then add a parameter named "TYPE" whose value is the [value](#)<sup>p797</sup> of that property to *parameters*.

**If the property's [value](#)<sup>p797</sup> is not an [item](#)<sup>p793</sup> and its [name](#) is [sex](#)<sup>p801</sup>**

If this is the first such property to be found, set *sex* to the property's [value](#)<sup>p797</sup>.

**If the property's [value](#)<sup>p797</sup> is not an [item](#)<sup>p793</sup> and its [name](#) is [gender-identity](#)<sup>p801</sup>**

If this is the first such property to be found, set *gender-identity* to the property's [value](#)<sup>p797</sup>.

**Otherwise (the property's [value](#)<sup>p797</sup> is not an [item](#)<sup>p793</sup>)**

1. Let *value* be the property's [value](#)<sup>p797</sup>.
2. If *element* is one of the [URL property elements](#)<sup>p797</sup>, add a parameter with the name "VALUE" and the value "URI" to *parameters*.
3. Otherwise, if *name* is [bday](#)<sup>p801</sup> or [anniversary](#)<sup>p801</sup> and the *value* is a [valid date string](#)<sup>p83</sup>, add a parameter with the name "VALUE" and the value "DATE" to *parameters*.
4. Otherwise, if *name* is [rev](#)<sup>p806</sup> and the *value* is a [valid global date and time string](#)<sup>p87</sup>, add a parameter with the name "VALUE" and the value "DATE-TIME" to *parameters*.
5. Prefix every U+005C REVERSE SOLIDUS character (\) in *value* with another U+005C REVERSE SOLIDUS character (\).
6. Prefix every U+002C COMMA character (,) in *value* with a U+005C REVERSE SOLIDUS character (\).
7. Unless *name* is [geo](#)<sup>p804</sup>, prefix every U+003B SEMICOLON character (;) in *value* with a U+005C REVERSE SOLIDUS character (\).
8. Replace every U+000D CARRIAGE RETURN U+000A LINE FEED character pair (CRLF) in *value* with a U+005C REVERSE SOLIDUS character (\) followed by a U+006E LATIN SMALL LETTER N character (n).
9. Replace every remaining U+000D CARRIAGE RETURN (CR) or U+000A LINE FEED (LF) character in *value* with a U+005C REVERSE SOLIDUS character (\) followed by a U+006E LATIN SMALL LETTER N character (n).

3. [Add a vCard line](#)<sup>p810</sup> with the type *name*, the parameters *parameters*, and the value *value* to *output*.

12. If either *sex* or *gender-identity* has a value that is not the empty string, [add a vCard line](#)<sup>p810</sup> with the type "GENDER" and the value consisting of the concatenation of *sex*, a U+003B SEMICOLON character (;), and *gender-identity* to *output*.

13. [Add a vCard line](#)<sup>p810</sup> with the type "END" and the value "VCARD" to *output*.

When the above algorithm says that the user agent is to **add a vCard line** consisting of a type *type*, optionally some parameters, and a value *value* to a string *output*, it must run the following steps:

1. Let *line* be an empty string.
2. Append *type*, [converted to ASCII uppercase](#), to *line*.
3. If there are any parameters, then for each parameter, in the order that they were added, run these substeps:
  1. Append a U+003B SEMICOLON character (;) to *line*.
  2. Append the parameter's name to *line*.
  3. Append a U+003D EQUALS SIGN character (=) to *line*.
  4. Append the parameter's value to *line*.
4. Append a U+003A COLON character (:) to *line*.
5. Append *value* to *line*.
6. Let *maximum length* be 75.
7. While *line*'s [code point length](#) is greater than *maximum length*:
  1. Append the first *maximum length* code points of *line* to *output*.
  2. Remove the first *maximum length* code points from *line*.
  3. Append a U+000D CARRIAGE RETURN character (CR) to *output*.
  4. Append a U+000A LINE FEED character (LF) to *output*.
  5. Append a U+0020 SPACE character to *output*.
  6. Let *maximum length* be 74.
8. Append (what remains of) *line* to *output*.
9. Append a U+000D CARRIAGE RETURN character (CR) to *output*.
10. Append a U+000A LINE FEED character (LF) to *output*.

When the steps above require the user agent to obtain the result of **collecting vCard subproperties** named *subname* in *subitem*, the user agent must run the following steps:

1. Let *value* be the empty string.
2. For each property named *subname* in the item *subitem*, run the following substeps:
  1. If the [value](#)<sup>p797</sup> of the property is itself an [item](#)<sup>p793</sup>, then skip this property.
  2. If this is not the first property named *subname* in *subitem* (ignoring any that were skipped by the previous step), then append a U+002C COMMA character (,) to *value*.
  3. Append the result of [escaping the vCard text string](#)<sup>p811</sup> given by the [value](#)<sup>p797</sup> of the property to *value*.
3. Return *value*.

When the steps above require the user agent to obtain the result of **collecting the first vCard subproperty** named *subname* in *subitem*, the user agent must run the following steps:

1. If there are no properties named *subname* in *subitem*, then return the empty string.
2. If the [value](#)<sup>p797</sup> of the first property named *subname* in *subitem* is an [item](#)<sup>p793</sup>, then return the empty string.
3. Return the result of [escaping the vCard text string](#)<sup>p811</sup> given by the [value](#)<sup>p797</sup> of the first property named *subname* in *subitem*.

When the above algorithms say the user agent is to **escape the vCard text string** *value*, the user agent must use the following steps:

1. Prefix every U+005C REVERSE SOLIDUS character (\) in *value* with another U+005C REVERSE SOLIDUS character (\).
2. Prefix every U+002C COMMA character (,) in *value* with a U+005C REVERSE SOLIDUS character (\).

3. Prefix every U+003B SEMICOLON character (;) in *value* with a U+005C REVERSE SOLIDUS character (\).
4. Replace every U+000D CARRIAGE RETURN U+000A LINE FEED character pair (CRLF) in *value* with a U+005C REVERSE SOLIDUS character (\) followed by a U+006E LATIN SMALL LETTER N character (n).
5. Replace every remaining U+000D CARRIAGE RETURN (CR) or U+000A LINE FEED (LF) character in *value* with a U+005C REVERSE SOLIDUS character (\) followed by a U+006E LATIN SMALL LETTER N character (n).
6. Return the mutated *value*.

#### Note

*This algorithm can generate invalid vCard output, if the input does not conform to the rules described for the <http://microformats.org/profile/hcard><sup>p800</sup> [item type](#)<sup>p793</sup> and [defined property names](#)<sup>p796</sup>.*

### 5.3.1.2 Examples <sup>p81</sup><sub>2</sub>

*This section is non-normative.*

#### Example

Here is a long example vCard for a fictional character called "Jack Bauer":

```
<section id="jack" itemscope itemtype="http://microformats.org/profile/hcard">
  <h1 itemprop="fn">
    <span itemprop="n" itemscope>
      <span itemprop="given-name">Jack</span>
      <span itemprop="family-name">Bauer</span>
    </span>
  </h1>
  
  <p itemprop="org" itemscope>
    <span itemprop="organization-name">Counter-Terrorist Unit</span>
    (<span itemprop="organization-unit">Los Angeles Division</span>)
  </p>
  <p>
    <span itemprop="adr" itemscope>
      <span itemprop="street-address">10201 W. Pico Blvd.</span><br>
      <span itemprop="locality">Los Angeles</span>,
      <span itemprop="region">CA</span>
      <span itemprop="postal-code">90064</span><br>
      <span itemprop="country-name">United States</span><br>
    </span>
    <span itemprop="geo">34.052339; -118.410623</span>
  </p>
  <h2>Assorted Contact Methods</h2>
  <ul>
    <li itemprop="tel" itemscope>
      <span itemprop="value">+1 (310) 597 3781</span> <span itemprop="type">work</span>
      <meta itemprop="type" content="voice">
    </li>
    <li><a itemprop="url" href="https://en.wikipedia.org/wiki/Jack_Bauer">I'm on Wikipedia</a>
    so you can leave a message on my user talk page.</li>
    <li><a itemprop="url" href="http://www.jackbauerfacts.com/">Jack Bauer Facts</a></li>
    <li itemprop="email"><a
href="mailto:j.bauer@la.ctu.gov.invalid">j.bauer@la.ctu.gov.invalid</a></li>
    <li itemprop="tel" itemscope>
      <span itemprop="value">+1 (310) 555 3781</span> <span>
      <meta itemprop="type" content="cell">mobile phone</span>
    </li>
  </ul>
  <ins datetime="2008-07-20 21:00:00+01:00">
```

```

<meta itemprop="rev" content="2008-07-20 21:00:00+01:00">
<p itemprop="tel" itemscope><strong>Update!</strong>
My new <span itemprop="type">home</span> phone number is
<span itemprop="value">01632 960 123</span>.</p>
</ins>
</section>

```

The odd line wrapping is needed because newlines are meaningful in microdata: newlines would be preserved in a conversion to, for example, the vCard format.

#### Example

This example shows a site's contact details (using the [address](#)<sup>p222</sup> element) containing an address with two street components:

```

<address itemscope itemType="http://microformats.org/profile/hcard">
<strong itemprop="fn"><span itemprop="n" itemscope><span itemprop="given-name">Alfred</span>
<span itemprop="family-name">Person</span></span></strong> <br>
<span itemprop="adr" itemscope>
<span itemprop="street-address">1600 Amphitheatre Parkway</span> <br>
<span itemprop="street-address">Building 43, Second Floor</span> <br>
<span itemprop="locality">Mountain View</span>,
<span itemprop="region">CA</span> <span itemprop="postal-code">94043</span>
</span>
</address>

```

#### Example

The vCard vocabulary can be used to just mark up people's names:

```

<span itemscope itemType="http://microformats.org/profile/hcard"
><span itemprop="fn"><span itemprop="n" itemscope><span itemprop="given-name"
>George</span> <span itemprop="family-name">Washington</span></span></span>
</span></span>

```

This creates a single item with a two name-value pairs, one with the name "fn" and the value "George Washington", and the other with the name "n" and a second item as its value, the second item having the two name-value pairs "given-name" and "family-name" with the values "George" and "Washington" respectively. This is defined to map to the following vCard:

```

BEGIN:VCARD
PROFILE:VCARD
VERSION:4.0
SOURCE:document's address
FN:George Washington
N:Washington;George;;
END:VCARD

```

### 5.3.2 vEvent <sup>p81</sup><sub>3</sub>

An item with the [item type](#)<sup>p793</sup> <http://microformats.org/profile/hcalendar#vevent> represents an event.

This vocabulary does not [support global identifiers for items](#)<sup>p794</sup>.

The following are the type's [defined property names](#)<sup>p796</sup>. They are based on the vocabulary defined in *Internet Calendaring and Scheduling Core Object Specification (iCalendar)*, where more information on how to interpret the values can be found. [\[RFC5545\]](#)<sup>p1481</sup>

#### Note

*Only the parts of the iCalendar vocabulary relating to events are used here; this vocabulary cannot express a complete iCalendar instance.*

## attach

Gives the address of an associated document for the event.

The [value<sup>p797</sup>](#) must be an [absolute URL](#).

Any number of properties with the name [attach<sup>p814</sup>](#) may be present within each [item<sup>p793</sup>](#) with the type [http://microformats.org/profile/hcalendar#vevent<sup>p813</sup>](http://microformats.org/profile/hcalendar#vevent).

## categories

Gives the name of a category or tag that the event could be classified as.

The [value<sup>p797</sup>](#) must be text.

Any number of properties with the name [categories<sup>p814</sup>](#) may be present within each [item<sup>p793</sup>](#) with the type [http://microformats.org/profile/hcalendar#vevent<sup>p813</sup>](http://microformats.org/profile/hcalendar#vevent).

## class

Gives the access classification of the information regarding the event.

The [value<sup>p797</sup>](#) must be text with one of the following values:

- public
- private
- confidential

### ⚠Warning!

***This is merely advisory and cannot be considered a confidentiality measure.***

A single property with the name [class<sup>p814</sup>](#) may be present within each [item<sup>p793</sup>](#) with the type [http://microformats.org/profile/hcalendar#vevent<sup>p813</sup>](http://microformats.org/profile/hcalendar#vevent).

## comment

Gives a comment regarding the event.

The [value<sup>p797</sup>](#) must be text.

Any number of properties with the name [comment<sup>p814</sup>](#) may be present within each [item<sup>p793</sup>](#) with the type [http://microformats.org/profile/hcalendar#vevent<sup>p813</sup>](http://microformats.org/profile/hcalendar#vevent).

## description

Gives a detailed description of the event.

The [value<sup>p797</sup>](#) must be text.

A single property with the name [description<sup>p814</sup>](#) may be present within each [item<sup>p793</sup>](#) with the type [http://microformats.org/profile/hcalendar#vevent<sup>p813</sup>](http://microformats.org/profile/hcalendar#vevent).

## geo

Gives the geographical position of the event.

The [value<sup>p797</sup>](#) must be text and must match the following syntax:

1. Optionally, either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
2. One or more [ASCII digits](#).
3. Optionally\*, a U+002E FULL STOP character (.) followed by one or more [ASCII digits](#).
4. A U+003B SEMICOLON character (;).
5. Optionally, either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
6. One or more [ASCII digits](#).
7. Optionally\*, a U+002E FULL STOP character (.) followed by one or more [ASCII digits](#).

The optional components marked with an asterisk (\*) should be included, and should have six digits each.

#### Note

*The value specifies latitude and longitude, in that order (i.e., "LAT LON" ordering), in decimal degrees. The longitude represents the location east and west of the prime meridian as a positive or negative real number, respectively. The latitude represents the location north and south of the equator as a positive or negative real number, respectively.*

A single property with the name [geo](#)<sup>p814</sup> may be present within each [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcalendar#vevent><sup>p813</sup>.

### location

Gives the location of the event.

The [value](#)<sup>p797</sup> must be text.

A single property with the name [location](#)<sup>p815</sup> may be present within each [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcalendar#vevent><sup>p813</sup>.

### resources

Gives a resource that will be needed for the event.

The [value](#)<sup>p797</sup> must be text.

Any number of properties with the name [resources](#)<sup>p815</sup> may be present within each [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcalendar#vevent><sup>p813</sup>.

### status

Gives the confirmation status of the event.

The [value](#)<sup>p797</sup> must be text with one of the following values:

- tentative
- confirmed
- canceled

A single property with the name [status](#)<sup>p815</sup> may be present within each [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcalendar#vevent><sup>p813</sup>.

### summary

Gives a short summary of the event.

The [value](#)<sup>p797</sup> must be text.

User agents should replace U+000A LINE FEED (LF) characters in the [value](#)<sup>p797</sup> by U+0020 SPACE characters when using the value.

A single property with the name [summary](#)<sup>p815</sup> may be present within each [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcalendar#vevent><sup>p813</sup>.

### dtend

Gives the date and time by which the event ends.

If the property with the name [dtend](#)<sup>p815</sup> is present within an [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcalendar#vevent><sup>p813</sup> that has a property with the name [dtstart](#)<sup>p816</sup> whose value is a [valid date string](#)<sup>p83</sup>, then the [value](#)<sup>p797</sup> of the property with the name [dtend](#)<sup>p815</sup> must be text that is a [valid date string](#)<sup>p83</sup> also. Otherwise, the [value](#)<sup>p797</sup> of the property must be text that is a [valid global date and time string](#)<sup>p87</sup>.

In either case, the [value](#)<sup>p797</sup> be later in time than the value of the [dtstart](#)<sup>p816</sup> property of the same [item](#)<sup>p793</sup>.

#### Note

*The time given by the [dtend](#)<sup>p815</sup> property is not inclusive. For day-long events, therefore, the [dtend](#)<sup>p815</sup> property's [value](#)<sup>p797</sup> will be the day after the end of the event.*

A single property with the name [dtend](#)<sup>p815</sup> may be present within each [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/>

[hcalendar#vevent](#)<sup>p813</sup>, so long as that <http://microformats.org/profile/hcalendar#vevent><sup>p813</sup> does not have a property with the name [duration](#)<sup>p816</sup>.

### dtstart

Gives the date and time at which the event starts.

The [value](#)<sup>p797</sup> must be text that is either a [valid date string](#)<sup>p83</sup> or a [valid global date and time string](#)<sup>p87</sup>.

Exactly one property with the name [dtstart](#)<sup>p816</sup> must be present within each [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcalendar#vevent><sup>p813</sup>.

### duration

Gives the duration of the event.

The [value](#)<sup>p797</sup> must be text that is a [valid vevent duration string](#)<sup>p817</sup>.

The duration represented is the sum of all the durations represented by integers in the value.

A single property with the name [duration](#)<sup>p816</sup> may be present within each [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcalendar#vevent><sup>p813</sup>, so long as that <http://microformats.org/profile/hcalendar#vevent><sup>p813</sup> does not have a property with the name [dtend](#)<sup>p815</sup>.

### transp

Gives whether the event is to be considered as consuming time on a calendar, for the purpose of free-busy time searches.

The [value](#)<sup>p797</sup> must be text with one of the following values:

- opaque
- transparent

A single property with the name [transp](#)<sup>p816</sup> may be present within each [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcalendar#vevent><sup>p813</sup>.

### contact

Gives the contact information for the event.

The [value](#)<sup>p797</sup> must be text.

Any number of properties with the name [contact](#)<sup>p816</sup> may be present within each [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcalendar#vevent><sup>p813</sup>.

### url

Gives a [URL](#) for the event.

The [value](#)<sup>p797</sup> must be an [absolute URL](#).

A single property with the name [url](#)<sup>p816</sup> may be present within each [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcalendar#vevent><sup>p813</sup>.

### uid

Gives a globally unique identifier corresponding to the event.

The [value](#)<sup>p797</sup> must be text.

A single property with the name [uid](#)<sup>p816</sup> may be present within each [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcalendar#vevent><sup>p813</sup>.

### exdate

Gives a date and time at which the event does not occur despite the recurrence rules.

The [value](#)<sup>p797</sup> must be text that is either a [valid date string](#)<sup>p83</sup> or a [valid global date and time string](#)<sup>p87</sup>.

Any number of properties with the name [exdate](#)<sup>p816</sup> may be present within each [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcalendar#vevent><sup>p813</sup>.

## rdate

Gives a date and time at which the event recurs.

The [value](#)<sup>p797</sup> must be text that is one of the following:

- A [valid date string](#)<sup>p83</sup>.
- A [valid global date and time string](#)<sup>p87</sup>.
- A [valid global date and time string](#)<sup>p87</sup> followed by a U+002F SOLIDUS character (/) followed by a second [valid global date and time string](#)<sup>p87</sup> representing a later time.
- A [valid global date and time string](#)<sup>p87</sup> followed by a U+002F SOLIDUS character (/) followed by a [valid vevent duration string](#)<sup>p817</sup>.

Any number of properties with the name [rdate](#)<sup>p817</sup> may be present within each [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcalendar#vevent><sup>p813</sup>.

## rrule

Gives a rule for finding dates and times at which the event occurs.

The [value](#)<sup>p797</sup> must be text that matches the RECUR value type defined in *iCalendar*. [\[RFC5545\]](#)<sup>p1481</sup>

A single property with the name [rrule](#)<sup>p817</sup> may be present within each [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcalendar#vevent><sup>p813</sup>.

## created

Gives the date and time at which the event information was first created in a calendaring system.

The [value](#)<sup>p797</sup> must be text that is a [valid global date and time string](#)<sup>p87</sup>.

A single property with the name [created](#)<sup>p817</sup> may be present within each [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcalendar#vevent><sup>p813</sup>.

## last-modified

Gives the date and time at which the event information was last modified in a calendaring system.

The [value](#)<sup>p797</sup> must be text that is a [valid global date and time string](#)<sup>p87</sup>.

A single property with the name [last-modified](#)<sup>p817</sup> may be present within each [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcalendar#vevent><sup>p813</sup>.

## sequence

Gives a revision number for the event information.

The [value](#)<sup>p797</sup> must be text that is a [valid non-negative integer](#)<sup>p77</sup>.

A single property with the name [sequence](#)<sup>p817</sup> may be present within each [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcalendar#vevent><sup>p813</sup>.

A string is a **valid vevent duration string** if it matches the following pattern:

1. A U+0050 LATIN CAPITAL LETTER P character (P).
2. One of the following:
  - A [valid non-negative integer](#)<sup>p77</sup> followed by a U+0057 LATIN CAPITAL LETTER W character (W). The integer represents a duration of that number of weeks.
  - At least one, and possible both in this order, of the following:
    1. A [valid non-negative integer](#)<sup>p77</sup> followed by a U+0044 LATIN CAPITAL LETTER D character (D). The integer represents a duration of that number of days.
    2. A U+0054 LATIN CAPITAL LETTER T character (T) followed by any one of the following, or the first and second of the following in that order, or the second and third of the following in that order, or all three of

the following in this order:

1. A [valid non-negative integer](#)<sup>p77</sup> followed by a U+0048 LATIN CAPITAL LETTER H character (H). The integer represents a duration of that number of hours.
2. A [valid non-negative integer](#)<sup>p77</sup> followed by a U+004D LATIN CAPITAL LETTER M character (M). The integer represents a duration of that number of minutes.
3. A [valid non-negative integer](#)<sup>p77</sup> followed by a U+0053 LATIN CAPITAL LETTER S character (S). The integer represents a duration of that number of seconds.

### 5.3.2.1 Conversion to iCalendar <sup>p81</sup><sub>8</sub>

Given a list of nodes *nodes* in a [Document](#)<sup>p130</sup>, a user agent must run the following algorithm to **extract any vEvent data represented by those nodes**:

1. If none of the nodes in *nodes* are [items](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcalendar#vevent><sup>p813</sup>, then there is no vEvent data. Abort the algorithm, returning nothing.
2. Let *output* be an empty string.
3. [Add an iCalendar line](#)<sup>p819</sup> with the type "BEGIN" and the value "VCALENDAR" to *output*.
4. [Add an iCalendar line](#)<sup>p819</sup> with the type "PRODID" and the value equal to a user-agent-specific string representing the user agent to *output*.
5. [Add an iCalendar line](#)<sup>p819</sup> with the type "VERSION" and the value "2.0" to *output*.
6. For each node *node* in *nodes* that is an [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcalendar#vevent><sup>p813</sup>, run the following steps:

1. [Add an iCalendar line](#)<sup>p819</sup> with the type "BEGIN" and the value "VEVENT" to *output*.
2. [Add an iCalendar line](#)<sup>p819</sup> with the type "DTSTAMP" and a value consisting of an iCalendar DATE-TIME string representing the current date and time, with the annotation "VALUE=DATE-TIME", to *output*. [\[RFC5545\]](#)<sup>p1481</sup>
3. For each element *element* that is [a property of the item](#)<sup>p798</sup> *node*: for each name *name* in *element*'s [property names](#)<sup>p796</sup>, run the appropriate set of substeps from the following list:

**If the property's [value](#)<sup>p797</sup> is an [item](#)<sup>p793</sup>**

Skip the property.

**If the property is [dtend](#)<sup>p815</sup>**

**If the property is [dtstart](#)<sup>p816</sup>**

**If the property is [exdate](#)<sup>p816</sup>**

**If the property is [rdate](#)<sup>p817</sup>**

**If the property is [created](#)<sup>p817</sup>**

**If the property is [last-modified](#)<sup>p817</sup>**

Let *value* be the result of stripping all U+002D HYPHEN-MINUS (-) and U+003A COLON (:) characters from the property's [value](#)<sup>p797</sup>.

If the property's [value](#)<sup>p797</sup> is a [valid date string](#)<sup>p83</sup> then [add an iCalendar line](#)<sup>p819</sup> with the type *name* and the value *value* to *output*, with the annotation "VALUE=DATE".

Otherwise, if the property's [value](#)<sup>p797</sup> is a [valid global date and time string](#)<sup>p87</sup> then [add an iCalendar line](#)<sup>p819</sup> with the type *name* and the value *value* to *output*, with the annotation "VALUE=DATE-TIME".

Otherwise, skip the property.

**Otherwise**

[Add an iCalendar line](#)<sup>p819</sup> with the type *name* and the property's [value](#)<sup>p797</sup> to *output*.

4. [Add an iCalendar line](#)<sup>p819</sup> with the type "END" and the value "VEVENT" to *output*.

7. [Add an iCalendar line](#)<sup>p819</sup> with the type "END" and the value "VCALENDAR" to *output*.

When the above algorithm says that the user agent is to **add an iCalendar line** consisting of a type *type*, a value *value*, and optionally an annotation, to a string *output*, it must run the following steps:

1. Let *line* be an empty string.
2. Append *type*, [converted to ASCII uppercase](#), to *line*.
3. If there is an annotation:
  1. Append a U+003B SEMICOLON character (;) to *line*.
  2. Append the annotation to *line*.
4. Append a U+003A COLON character (:) to *line*.
5. Prefix every U+005C REVERSE SOLIDUS character (\) in *value* with another U+005C REVERSE SOLIDUS character (\).
6. Prefix every U+002C COMMA character (,) in *value* with a U+005C REVERSE SOLIDUS character (\).
7. Prefix every U+003B SEMICOLON character (;) in *value* with a U+005C REVERSE SOLIDUS character (\).
8. Replace every U+000D CARRIAGE RETURN U+000A LINE FEED character pair (CRLF) in *value* with a U+005C REVERSE SOLIDUS character (\) followed by a U+006E LATIN SMALL LETTER N character (n).
9. Replace every remaining U+000D CARRIAGE RETURN (CR) or U+000A LINE FEED (LF) character in *value* with a U+005C REVERSE SOLIDUS character (\) followed by a U+006E LATIN SMALL LETTER N character (n).
10. Append *value* to *line*.
11. Let *maximum length* be 75.
12. While *line*'s [code point length](#) is greater than *maximum length*:
  1. Append the first *maximum length* code points of *line* to *output*.
  2. Remove the first *maximum length* code points from *line*.
  3. Append a U+000D CARRIAGE RETURN character (CR) to *output*.
  4. Append a U+000A LINE FEED character (LF) to *output*.
  5. Append a U+0020 SPACE character to *output*.
  6. Let *maximum length* be 74.
13. Append (what remains of) *line* to *output*.
14. Append a U+000D CARRIAGE RETURN character (CR) to *output*.
15. Append a U+000A LINE FEED character (LF) to *output*.

#### Note

*This algorithm can generate invalid iCalendar output, if the input does not conform to the rules described for the <http://microformats.org/profile/hcalendar#vevent><sup>p813</sup> [item type](#)<sup>p793</sup> and [defined property names](#)<sup>p796</sup>.*

### 5.3.2.2 Examples <sup>p81</sup><sub>9</sub>

*This section is non-normative.*

#### Example

Here is an example of a page that uses the vEvent vocabulary to mark up an event:

```
<body itemscope itemtype="http://microformats.org/profile/hcalendar#vevent">
...
```

```

<h1 itemprop="summary">Bluesday Tuesday: Money Road</h1>
...
<time itemprop="dtstart" datetime="2009-05-05T19:00:00Z">May 5th @ 7pm</time>
(until <time itemprop="dtend" datetime="2009-05-05T21:00:00Z">9pm</time>)
...
<a href="http://livebrum.co.uk/2009/05/05/bluesday-tuesday-money-road"
  rel="bookmark" itemprop="url">Link to this page</a>
...
<p>Location: <span itemprop="location">The RoadHouse</span></p>
...
<p><input type="button" value="Add to Calendar"
  onclick="location = getCalendar(this)"></p>
...
<meta itemprop="description" content="via livebrum.co.uk">
</body>

```

The `getCalendar()` function is left as an exercise for the reader.

The same page could offer some markup, such as the following, for copy-and-pasting into blogs:

```

<div itemscope itemtype="http://microformats.org/profile/hcalendar#vevent">
  <p>I'm going to
  <strong itemprop="summary">Bluesday Tuesday: Money Road</strong>,
  <time itemprop="dtstart" datetime="2009-05-05T19:00:00Z">May 5th at 7pm</time>
  to <time itemprop="dtend" datetime="2009-05-05T21:00:00Z">9pm</time>,
  at <span itemprop="location">The RoadHouse</span>!</p>
  <p><a href="http://livebrum.co.uk/2009/05/05/bluesday-tuesday-money-road"
    itemprop="url">See this event on livebrum.co.uk</a>.</p>
  <meta itemprop="description" content="via livebrum.co.uk">
</div>

```

### 5.3.3 Licensing works <sup>p82</sup><sub>0</sub>

An item with the [item type](#)<sup>p793</sup> <http://n.whatwg.org/work> represents a work (e.g. an article, an image, a video, a song, etc.). This type is primarily intended to allow authors to include licensing information for works.

The following are the type's [defined property names](#)<sup>p796</sup>.

#### work

Identifies the work being described.

The [value](#)<sup>p797</sup> must be an [absolute URL](#).

Exactly one property with the name [work](#)<sup>p820</sup> must be present within each [item](#)<sup>p793</sup> with the type <http://n.whatwg.org/work><sup>p820</sup>.

#### title

Gives the name of the work.

A single property with the name [title](#)<sup>p820</sup> may be present within each [item](#)<sup>p793</sup> with the type <http://n.whatwg.org/work><sup>p820</sup>.

#### author

Gives the name or contact information of one of the authors or creators of the work.

The [value](#)<sup>p797</sup> must be either an [item](#)<sup>p793</sup> with the type <http://microformats.org/profile/hcard><sup>p800</sup>, or text.

Any number of properties with the name [author](#)<sup>p820</sup> may be present within each [item](#)<sup>p793</sup> with the type <http://n.whatwg.org/work><sup>p820</sup>.

## license

Identifies one of the licenses under which the work is available.

The [value](#)<sup>p797</sup> must be an [absolute URL](#).

Any number of properties with the name [license](#)<sup>p821</sup> may be present within each [item](#)<sup>p793</sup> with the type [http://n.whatwg.org/work](#)<sup>p820</sup>.

### 5.3.3.1 Examples § p821

*This section is non-normative.*

#### Example

This example shows an embedded image entitled *My Pond*, licensed under the Creative Commons Attribution-Share Alike 4.0 International License and the MIT license simultaneously.

```
<figure itemscope itemtype="http://n.whatwg.org/work">
  
  <figcaption>
    <p><cite itemprop="title">My Pond</cite></p>
    <p><small>Licensed under the <a itemprop="license"
      href="https://creativecommons.org/licenses/by-sa/4.0/">Creative
      Commons Attribution-Share Alike 4.0 International License</a>
      and the <a itemprop="license"
      href="http://www.opensource.org/licenses/mit-license.php">MIT
      license</a>.</small>
    </figcaption>
  </figure>
```

## 5.4 Converting HTML to other formats § p821

### 5.4.1 JSON § p821

Given a list of nodes *nodes* in a [Document](#)<sup>p130</sup>, a user agent must run the following algorithm to **extract the microdata from those nodes into a JSON form**:

1. Let *result* be an empty object.
2. Let *items* be an empty array.
3. For each *node* in *nodes*, check if the element is a [top-level microdata item](#)<sup>p798</sup>, and if it is then [get the object](#)<sup>p821</sup> for that element and add it to *items*.
4. Add an entry to *result* called "items" whose value is the array *items*.
5. Return the result of serializing *result* to JSON in the shortest possible way (meaning no whitespace between tokens, no unnecessary zero digits in numbers, and only using Unicode escapes in strings for characters that do not have a dedicated escape sequence), and with a lowercase "e" used, when appropriate, in the representation of any numbers. [\[JSON\]](#)<sup>p1479</sup>

#### Note

*This algorithm returns an object with a single property that is an array, instead of just returning an array, so that it is possible to extend the algorithm in the future if necessary.*

When the user agent is to **get the object** for an item *item*, optionally with a list of elements *memory*, it must run the following substeps:

1. Let *result* be an empty object.

2. If no *memory* was passed to the algorithm, let *memory* be an empty list.
3. Add *item* to *memory*.
4. If the *item* has any [item types](#)<sup>p793</sup>, add an entry to *result* called "type" whose value is an array listing the [item types](#)<sup>p793</sup> of *item*, in the order they were specified on the [itemtype](#)<sup>p793</sup> attribute.
5. If the *item* has a [global identifier](#)<sup>p794</sup>, add an entry to *result* called "id" whose value is the [global identifier](#)<sup>p794</sup> of *item*.
6. Let *properties* be an empty object.
7. For each element *element* that has one or more [property names](#)<sup>p796</sup> and is one of [the properties of the item](#)<sup>p798</sup> *item*, in the order those elements are given by the algorithm that returns [the properties of an item](#)<sup>p798</sup>, run the following substeps:
  1. Let *value* be the [property value](#)<sup>p797</sup> of *element*.
  2. If *value* is an [item](#)<sup>p793</sup>, then: If *value* is in *memory*, then let *value* be the string "ERROR". Otherwise, [get the object](#)<sup>p821</sup> for *value*, passing a copy of *memory*, and then replace *value* with the object returned from those steps.
  3. For each name *name* in *element*'s [property names](#)<sup>p796</sup>, run the following substeps:
    1. If there is no entry named *name* in *properties*, then add an entry named *name* to *properties* whose value is an empty array.
    2. Append *value* to the entry named *name* in *properties*.
8. Add an entry to *result* called "properties" whose value is the object *properties*.
9. Return *result*.

#### Example

For example, take this markup:

```
<!DOCTYPE HTML>
<html lang="en">
<title>My Blog</title>
<article itemscope itemtype="http://schema.org/BlogPosting">
  <header>
    <h1 itemprop="headline">Progress report</h1>
    <p><time itemprop="datePublished" datetime="2013-08-29">today</time></p>
    <link itemprop="url" href="?comments=0">
  </header>
  <p>All in all, he's doing well with his swim lessons. The biggest thing was he had trouble
  putting his head in, but we got it down.</p>
  <section>
    <h1>Comments</h1>
    <article itemprop="comment" itemscope itemtype="http://schema.org/UserComments" id="c1">
      <link itemprop="url" href="#c1">
      <footer>
        <p>Posted by: <span itemprop="creator" itemscope itemtype="http://schema.org/Person">
          <span itemprop="name">Greg</span>
        </span></p>
        <p><time itemprop="commentTime" datetime="2013-08-29">15 minutes ago</time></p>
      </footer>
      <p>Ha!</p>
    </article>
    <article itemprop="comment" itemscope itemtype="http://schema.org/UserComments" id="c2">
      <link itemprop="url" href="#c2">
      <footer>

6 User interaction § p82  
4

6.1 The **hidden** attribute § p824  
4

All [HTML elements](#)<sup>p45</sup> may have the **hidden** content attribute set. The **hidden**<sup>p824</sup> attribute is an [enumerated attribute](#)<sup>p76</sup> with the following keywords and states:

Keyword	State	Brief description
<b>hidden</b> (the empty string)	<b>hidden</b>	Will not be rendered.
<b>until-found</b>	<b>hidden until found</b>	Will not be rendered, but content inside will be accessible to <a href="#">find-in-page</a> <sup>p862</sup> and <a href="#">fragment navigation</a> <sup>p1021</sup> .

The attribute's [missing value default](#)<sup>p76</sup> is the **not hidden** state, and its [invalid value default](#)<sup>p76</sup> is the **hidden**<sup>p824</sup> state.

When an element has the **hidden**<sup>p824</sup> attribute in the **hidden**<sup>p824</sup> state, it indicates that the element is not yet, or is no longer, directly relevant to the page's current state, or that it is being used to declare content to be reused by other parts of the page as opposed to being directly accessed by the user. User agents should not render elements that are in the **hidden**<sup>p824</sup> state. This requirement may be implemented indirectly through the style layer. For example, a web browser could implement these requirements [using the rules suggested in the Rendering section](#)<sup>p1390</sup>.

When an element has the **hidden**<sup>p824</sup> attribute in the **hidden until found**<sup>p824</sup> state, it indicates that the element is hidden like the **hidden**<sup>p824</sup> state but the content inside the element will be accessible to [find-in-page](#)<sup>p862</sup> and [fragment navigation](#)<sup>p1021</sup>. When these features attempt to scroll to a target which is in the element's subtree, the user agent will remove the **hidden**<sup>p824</sup> attribute in order to reveal the content before scrolling to it. In addition to removing the **hidden**<sup>p824</sup> attribute, an event named [beforematch](#)<sup>p1471</sup> is also fired on the element before the **hidden**<sup>p824</sup> attribute is removed.

Web browsers will use 'content-visibility: hidden' instead of 'display: none' when the **hidden**<sup>p824</sup> attribute is in the **hidden until found**<sup>p824</sup> state, as specified in the [Rendering section](#)<sup>p1390</sup>.

Note

Because this attribute is typically implemented using CSS, it's also possible to override it using CSS. For instance, a rule that applies 'display: block' to all elements will cancel the effects of the **hidden**<sup>p824</sup> state. Authors therefore have to take care when writing their style sheets to make sure that the attribute is still styled as expected. In addition, legacy user agents which don't support the **hidden until found**<sup>p824</sup> state will have 'display: none' instead of 'content-visibility: hidden', so authors are encouraged to make sure that their style sheets don't change the 'display' or 'content-visibility' properties of **hidden until found**<sup>p824</sup> elements.

Since elements with the **hidden**<sup>p824</sup> attribute in the **hidden until found**<sup>p824</sup> state use 'content-visibility: hidden' instead of 'display: none', there are two caveats of the **hidden until found**<sup>p824</sup> state that make it different from the **hidden**<sup>p824</sup> state:

1. The element needs to be affected by [layout containment](#) in order to be revealed by find-in-page. This means that if the element in the **hidden until found**<sup>p824</sup> state has a 'display' value of 'none', 'contents', or 'inline', then the element will not be revealed by find-in-page.
2. The element will still have a [generated box](#) when in the **hidden until found**<sup>p824</sup> state, which means that borders, margin, and padding will still be rendered around the element.

Example

In the following skeletal example, the attribute is used to hide the web game's main screen until the user logs in:

```
<h1>The Example Game</h1>
<section id="login">
  <h2>Login</h2>
  <form>
    ...
    <!-- calls login() once the user's credentials have been checked -->
  </form>
</script>
```

```

function login() {
  // switch screens
  document.getElementById('login').hidden = true;
  document.getElementById('game').hidden = false;
}
</script>
</section>
<section id="game" hidden>
  ...
</section>

```

The [hidden](#)<sup>p824</sup> attribute must not be used to hide content that could legitimately be shown in another presentation. For example, it is incorrect to use [hidden](#)<sup>p824</sup> to hide panels in a tabbed dialog, because the tabbed interface is merely a kind of overflow presentation — one could equally well just show all the form controls in one big page with a scrollbar. It is similarly incorrect to use this attribute to hide content just from one presentation — if something is marked [hidden](#)<sup>p824</sup>, it is hidden from all presentations, including, for instance, screen readers.

Elements that are not themselves [hidden](#)<sup>p824</sup> must not [hyperlink](#)<sup>p302</sup> to elements that are [hidden](#)<sup>p824</sup>. The `for` attributes of [label](#)<sup>p518</sup> and [output](#)<sup>p584</sup> elements that are not themselves [hidden](#)<sup>p824</sup> must similarly not refer to elements that are [hidden](#)<sup>p824</sup>. In both cases, such references would cause user confusion.

Elements and scripts may, however, refer to elements that are [hidden](#)<sup>p824</sup> in other contexts.

#### Example

For example, it would be incorrect to use the [href](#)<sup>p303</sup> attribute to link to a section marked with the [hidden](#)<sup>p824</sup> attribute. If the content is not applicable or relevant, then there is no reason to link to it.

It would be fine, however, to use the ARIA [aria-describedby](#) attribute to refer to descriptions that are themselves [hidden](#)<sup>p824</sup>. While hiding the descriptions implies that they are not useful alone, they could be written in such a way that they are useful in the specific context of being referenced from the elements that they describe.

Similarly, a [canvas](#)<sup>p677</sup> element with the [hidden](#)<sup>p824</sup> attribute could be used by a scripted graphics engine as an off-screen buffer, and a form control could refer to a hidden [form](#)<sup>p514</sup> element using its [form](#)<sup>p598</sup> attribute.

Elements in a section hidden by the [hidden](#)<sup>p824</sup> attribute are still active, e.g. scripts and form controls in such sections still execute and submit respectively. Only their presentation to the user changes.

The [hidden](#) getter steps are:

1. If the [hidden](#)<sup>p824</sup> attribute is in the [hidden until found](#)<sup>p824</sup> state, then return "[until-found](#)<sup>p824</sup>".
2. If the [hidden](#)<sup>p824</sup> attribute is set, then return true.
3. Return false.

The [hidden](#)<sup>p825</sup> setter steps are:

1. If the given value is a string that is an [ASCII case-insensitive](#) match for "[until-found](#)<sup>p824</sup>", then set the [hidden](#)<sup>p824</sup> attribute to "[until-found](#)<sup>p824</sup>".
2. Otherwise, if the given value is false, then remove the [hidden](#)<sup>p824</sup> attribute.
3. Otherwise, if the given value is the empty string, then remove the [hidden](#)<sup>p824</sup> attribute.
4. Otherwise, if the given value is null, then remove the [hidden](#)<sup>p824</sup> attribute.
5. Otherwise, if the given value is 0, then remove the [hidden](#)<sup>p824</sup> attribute.
6. Otherwise, if the given value is NaN, then remove the [hidden](#)<sup>p824</sup> attribute.
7. Otherwise, set the [hidden](#)<sup>p824</sup> attribute to the empty string.

The **ancestor hidden-until-found revealing algorithm** is to run the following steps on *currentNode*:

1. While *currentNode* has a parent node within the [flat tree](#):
  1. If *currentNode* has the [hidden](#)<sup>p824</sup> attribute in the [hidden until found](#)<sup>p824</sup> state, then:
    1. [Fire an event](#) named [beforematch](#)<sup>p1471</sup> at *currentNode*.
    2. Remove the [hidden](#)<sup>p824</sup> attribute from *currentNode*.
  2. Set *currentNode* to the parent node of *currentNode* within the [flat tree](#).

## 6.2 Page visibility §<sup>p82</sup><sub>6</sub>

A [traversable navigable](#)<sup>p990</sup>'s [system visibility state](#)<sup>p990</sup>, including its initial value upon creation, is determined by the user agent. It represents, for example, whether the browser window is minimized, a browser tab is currently in the background, or a system element such as a task switcher obscures the page.

When a user-agent determines that the [system visibility state](#)<sup>p990</sup> for [traversable navigable](#)<sup>p990</sup> *traversable* has changed to *newState*, it must run the following steps:

1. Let *navigables* be the [inclusive descendant navigables](#)<sup>p994</sup> of *traversable*'s [active document](#)<sup>p989</sup>.
2. [For each](#) *navigable* of *navigables* **in what order?**:
  1. Let *document* be *navigable*'s [active document](#)<sup>p989</sup>.
  2. [Queue a global task](#)<sup>p1125</sup> on the [user interaction task source](#)<sup>p1134</sup> given *document*'s [relevant global object](#)<sup>p1083</sup> to [update the visibility state](#)<sup>p826</sup> of *document* with *newState*.

A [Document](#)<sup>p130</sup> has a **visibility state**, which is either "hidden" or "visible", initially set to "hidden".

The **visibilityState** getter steps are to return [this](#)'s [visibility state](#)<sup>p826</sup>.

The **hidden** getter steps are to return true if [this](#)'s [visibility state](#)<sup>p826</sup> is "hidden", otherwise false.

To **update the visibility state** of [Document](#)<sup>p130</sup> *document* to *visibilityState*:

1. If *document*'s [visibility state](#)<sup>p826</sup> equals *visibilityState*, then return.
2. Set *document*'s [visibility state](#)<sup>p826</sup> to *visibilityState*.
3. [Queue](#) a new [VisibilityStateEntry](#)<sup>p827</sup> whose [visibility state](#)<sup>p827</sup> is *visibilityState* and whose [timestamp](#)<sup>p827</sup> is the [current high resolution time](#) given *document*'s [relevant global object](#)<sup>p1083</sup>.
4. Run the [screen orientation change steps](#) with *document*. [\[SCREENORIENTATION\]](#)<sup>p1482</sup>
5. Run the [view transition page visibility change steps](#) with *document*.
6. Run any **page visibility change steps** which may be defined in other specifications, with [visibility state](#)<sup>p826</sup> and *document*.

It would be better if specification authors sent a pull request to add calls from here into their specifications directly, instead of using the [page visibility change steps](#)<sup>p826</sup> hook, to ensure well-defined cross-specification call order. As of the time of this writing the following specifications are known to have [page visibility change steps](#)<sup>p826</sup>, which will be run in an unspecified order: *Device Posture API* and *Web NFC*. [\[DEVICEPOSTURE\]](#)<sup>p1478</sup> [\[WEBNFC\]](#)<sup>p1484</sup>

7. Fire an event named [visibilitychange](#)<sup>p1472</sup> at *document*, with its **bubbles** attribute initialized to true.

### 6.2.1 The [VisibilityStateEntry](#)<sup>p827</sup> interface §<sup>p82</sup><sub>6</sub>

The [VisibilityStateEntry](#)<sup>p827</sup> interface exposes visibility changes to the document, from the moment the document becomes active.

### Example

For example, this allows JavaScript code in the page to examine correlation between visibility changes and paint timing:

```
function wasHiddenBeforeFirstContentfulPaint() {
  const fcpEntry = performance.getEntriesByName("first-contentful-paint")[0];
  const visibilityStateEntries = performance.getEntriesByType("visibility-state");
  return visibilityStateEntries.some(e =>
    e.startTime < fcpEntry.startTime &&
    e.name === "hidden");
}
```

### Note

Since hiding a page can cause throttling of rendering and other user-agent operations, it is common to use visibility changes as an indication that such throttling has occurred. However, other things could also cause throttling in different browsers, such as long periods of inactivity.

IDL [Exposed=(Window)]

```
interface VisibilityStateEntry : PerformanceEntry {
  readonly attribute DOMString name;           // shadows inherited name
  readonly attribute DOMString entryType;       // shadows inherited entryType
  readonly attribute DOMHighResTimeStamp startTime; // shadows inherited startTime
  readonly attribute unsigned long duration;    // shadows inherited duration
};
```

The [VisibilityStateEntry](#)<sup>p827</sup> has an associated [DOMHighResTimeStamp](#) **timestamp**.

The [VisibilityStateEntry](#)<sup>p827</sup> has an associated "visible" or "hidden" **visibility state**.

The **name** getter steps are to return [this's visibility state](#)<sup>p827</sup>.

The **entryType** getter steps are to return "visibility-state".

The **startTime** getter steps are to return [this's timestamp](#)<sup>p827</sup>.

The **duration** getter steps are to return zero.

## 6.3 Inert subtrees §<sup>p82</sup> 7

### Note

See also [inert](#)<sup>p828</sup> for an explanation of the attribute of the same name.

A node (in particular elements and text nodes) can be **inert**. When a node is [inert](#)<sup>p827</sup>:

- Hit-testing must act as if the '[pointer-events](#)' CSS property were set to 'none'.
- Text selection functionality must act as if the '[user-select](#)' CSS property were set to 'none'.
- If it is [editable](#), the node behaves as if it were non-editable.
- The user agent should ignore the node for the purposes of [find-in-page](#)<sup>p862</sup>.

### Note

Inert nodes generally cannot be focused, and user agents do not expose the inert nodes to accessibility APIs or assistive technologies. Inert nodes that are [commands](#)<sup>p643</sup> will become inoperable to users, in the manner described above.

User agents may allow the user to override the restrictions on [find-in-page](#)<sup>p862</sup> and text selection, however.

By default, a node is not [inert](#)<sup>p827</sup>.

### 6.3.1 Modal dialogs and inert subtrees <sup>§ p82</sup><sub>8</sub>

A [Document](#)<sup>p130</sup> *document* is **blocked by a modal dialog** *subject* if *subject* is the topmost [dialog](#)<sup>p646</sup> element in *document*'s [top layer](#). While *document* is so blocked, every node that is [connected](#) to *document*, with the exception of the *subject* element and its [flat tree](#) descendants, must become [inert](#)<sup>p827</sup>.

*subject* can additionally become [inert](#)<sup>p827</sup> via the [inert](#)<sup>p828</sup> attribute, but only if specified on *subject* itself (i.e., *subject* escapes inertness of ancestors); *subject*'s [flat tree](#) descendants can become [inert](#)<sup>p827</sup> in a similar fashion.

#### Note

The [dialog](#)<sup>p646</sup> element's [showModal\(\)](#)<sup>p649</sup> method causes this mechanism to trigger, by adding the [dialog](#)<sup>p646</sup> element to its [node document's top layer](#).

### 6.3.2 The [inert](#) attribute <sup>§ p82</sup><sub>8</sub>

The [inert](#)<sup>p828</sup> attribute is a [boolean attribute](#)<sup>p75</sup> that indicates, by its presence, that the element and all its [flat tree](#) descendants which don't otherwise escape inertness (such as modal dialogs) are to be made [inert](#)<sup>p827</sup> by the user agent.

An inert subtree should not contain any content or controls which are critical to understanding or using aspects of the page which are not in the inert state. Content in an inert subtree will not be perceivable by all users, or interactive. Authors should not specify elements as inert unless the content they represent are also visually obscured in some way. In most cases, authors should not specify the [inert](#)<sup>p827</sup> attribute on individual form controls. In these instances, the [disabled](#)<sup>p601</sup> attribute is probably more appropriate.

#### Example

The following example shows how to mark partially loaded content, visually obscured by a "loading" message, as inert.

```
<section aria-labelledby=s1>
  <h3 id=s1>Population by City</h3>
  <div class=container>
    <div class=loading><p>Loading...</p></div>
    <div inert>
      <form>
        <fieldset>
          <legend>Date range</legend>
          <div>
            <label for=start>Start</label>
            <input type=date id=start>
          </div>
          <div>
            <label for=end>End</label>
            <input type=date id=end>
          </div>
          <div>
            <button>Apply</button>
          </div>
        </fieldset>
      </form>
      <table>
        <caption>From 20-- to 20--</caption>
        <thead>
          <tr>
            <th>City</th>
            <th>State</th>
            <th>20-- Population</th>
            <th>20-- Population</th>
            <th>Percentage change</th>
          </tr>
        </thead>
        <tbody>
```

```

<!-- ... -->
</tbody>
</table>
</div>
</div>
</section>

```

## Population by City

Date range

Start  End

From 20-- to 20--

City	State	20-- Population	Loading...	Percentage change

The "loading" overlay obscures the inert content, making it visually apparent that the inert content is not presently accessible. Notice that the heading and "loading" text are not descendants of the element with the [inert](#)<sup>p827</sup> attribute. This will ensure this text is accessible to all users, while the inert content cannot be interacted with by anyone.

### Note

By default, there is no persistent visual indication of an element or its subtree being inert. Appropriate visual styles for such content is often context-dependent. For instance, an inert off-screen navigation panel would not require a default style, as its off-screen position visually obscures the content. Similarly, a modal [dialog](#)<sup>p646</sup> element's backdrop will serve as the means to visually obscure the inert content of the web page, rather than styling the inert content specifically.

However, for many other situations authors are strongly encouraged to clearly mark what parts of their document are active and which are inert, to avoid user confusion. In particular, it is worth remembering that not all users can see all parts of a page at once; for example, users of screen readers, users on small devices or with magnifiers, and even users using particularly small windows might not be able to see the active part of a page and might get frustrated if inert sections are not obviously inert.

The [inert](#) IDL attribute must [reflect](#)<sup>p104</sup> the content attribute of the same name.

## 6.4 Tracking user activation § p829

To prevent abuse of certain APIs that could be annoying to users (e.g., opening popups or vibrating phones), user agents allow these APIs only when the user is actively interacting with the web page or has interacted with the page at least once. This "active interaction" state is maintained through the mechanisms defined in this section.

### 6.4.1 Data model § p829

For the purpose of tracking user activation, each [Window](#)<sup>p922</sup> *W* has two relevant values:

- A **last activation timestamp**, which is either a [DOMHighResTimeStamp](#), positive infinity (indicating that *W* has never been activated), or negative infinity (indicating that the activation has been [consumed](#)<sup>p831</sup>). Initially positive infinity.
- A **last history-action activation timestamp**, which is either a [DOMHighResTimeStamp](#) or positive infinity, initially positive infinity.

A user agent also defines a **transient activation duration**, which is a constant number indicating how long a user activation is available for certain [user activation-gated APIs](#)<sup>p831</sup> (e.g., for opening popups).

## Note

The [transient activation duration](#)<sup>p829</sup> is expected be at most a few seconds, so that the user can possibly perceive the link between an interaction with the page and the page calling the activation-gated API.

We then have the following boolean user activation states for  $W$ :

### Sticky activation

When the [current high resolution time](#) given  $W$  is greater than or equal to the [last activation timestamp](#)<sup>p829</sup> in  $W$ ,  $W$  is said to have [sticky activation](#)<sup>p830</sup>.

This is  $W$ 's historical activation state, indicating whether the user has ever interacted in  $W$ . It starts false, then changes to true (and never changes back to false) when  $W$  gets the very first [activation notification](#)<sup>p830</sup>.

### Transient activation

When the [current high resolution time](#) given  $W$  is greater than or equal to the [last activation timestamp](#)<sup>p829</sup> in  $W$ , and less than the [last activation timestamp](#)<sup>p829</sup> in  $W$  plus the [transient activation duration](#)<sup>p829</sup>, then  $W$  is said to have [transient activation](#)<sup>p830</sup>.

This is  $W$ 's current activation state, indicating whether the user has interacted in  $W$  recently. This starts with a false value, and remains true for a limited time after every [activation notification](#)<sup>p830</sup>  $W$  gets.

The [transient activation](#)<sup>p830</sup> state is considered **expired** if it becomes false because the [transient activation duration](#)<sup>p829</sup> time has elapsed since the last user activation. Note that it can become false even before the expiry time through an [activation consumption](#)<sup>p831</sup>.

### History-action activation

When the [last history-action activation timestamp](#)<sup>p829</sup> of  $W$  is not equal to the [last activation timestamp](#)<sup>p829</sup> of  $W$ , then  $W$  is said to have [history-action activation](#)<sup>p830</sup>.

This is a special variant of user activation, used to allow access to certain session history APIs which, if used too frequently, would make it harder for the user to traverse back using [browser UI](#)<sup>p1069</sup>. It starts with a false value, and becomes true whenever the user interacts with  $W$ , but is reset to false through [history-action activation consumption](#)<sup>p831</sup>. This ensures such APIs cannot be used multiple times in a row without an intervening user activation. But unlike [transient activation](#)<sup>p830</sup>, there is no time limit within which such APIs must be used.

## Note

The [last activation timestamp](#)<sup>p829</sup> and [last history-action activation timestamp](#)<sup>p829</sup> are retained even after the [Document](#)<sup>p130</sup> changes its [fully active](#)<sup>p1003</sup> status (e.g., after navigating away from a [Document](#)<sup>p130</sup>, or navigating to a cached [Document](#)<sup>p130</sup>). This means [sticky activation](#)<sup>p830</sup> state spans multiple navigations as long as the same [Document](#)<sup>p130</sup> gets reused. For the transient activation state, the original [expiry](#)<sup>p830</sup> time remains unchanged (i.e., the state still expires within the [transient activation duration](#)<sup>p829</sup> limit from the original [activation triggering input event](#)<sup>p831</sup>). It is important to consider this when deciding whether to base certain things off [sticky activation](#)<sup>p830</sup> or [transient activation](#)<sup>p830</sup>.

## 6.4.2 Processing model §<sup>p83</sup><sub>0</sub>

When a user interaction causes firing of an [activation triggering input event](#)<sup>p831</sup> in a [Document](#)<sup>p130</sup> document, the user agent must perform the following **activation notification** steps *before dispatching* the event:

1. **Assert:** document is [fully active](#)<sup>p1003</sup>.
2. Let *windows* be « document's [relevant global object](#)<sup>p1083</sup> ».
3. **Extend** *windows* with the [active window](#)<sup>p989</sup> of each of document's [ancestor navigables](#)<sup>p994</sup>.
4. **Extend** *windows* with the [active window](#)<sup>p989</sup> of each of document's [descendant navigables](#)<sup>p994</sup>, filtered to include only those [navigables](#)<sup>p989</sup> whose [active document](#)<sup>p989</sup>'s [origin](#) is [same origin](#)<sup>p899</sup> with document's [origin](#).
5. **For each** *window* in *windows*:
  1. Set *window*'s [last activation timestamp](#)<sup>p829</sup> to the [current high resolution time](#).
  2. **Notify the close watcher manager about user activation**<sup>p865</sup> given *window*.

An **activation triggering input event** is any event whose `isTrusted` attribute is true and whose `type` is one of:

- `"keydown"`, provided the key is neither the Esc key nor a shortcut key reserved by the user agent;
- `"mousedown"`;
- `"pointerdown"`, provided the event's `pointerType` is `"mouse"`;
- `"pointerup"`, provided the event's `pointerType` is not `"mouse"`; or
- `"touchend"`.

[Activation consuming APIs](#)<sup>p831</sup> defined in this and other specifications can **consume user activation** by performing the following steps, given a [Window](#)<sup>p922</sup> *W*:

1. If *W*'s [navigable](#)<sup>p923</sup> is null, then return.
2. Let *top* be *W*'s [navigable](#)<sup>p923</sup>'s [top-level traversable](#)<sup>p990</sup>.
3. Let *navigables* be the [inclusive descendant navigables](#)<sup>p994</sup> of *top*'s [active document](#)<sup>p989</sup>.
4. Let *windows* be the list of [Window](#)<sup>p922</sup> objects constructed by taking the [active window](#)<sup>p989</sup> of each item in *navigables*.
5. **For each** *window* in *windows*, if *window*'s [last activation timestamp](#)<sup>p829</sup> is not positive infinity, then set *window*'s [last activation timestamp](#)<sup>p829</sup> to negative infinity.

[History-action activation-consuming APIs](#)<sup>p831</sup> can **consume history-action user activation** by performing the following steps, given a [Window](#)<sup>p922</sup> *W*:

1. If *W*'s [navigable](#)<sup>p923</sup> is null, then return.
2. Let *top* be *W*'s [navigable](#)<sup>p923</sup>'s [top-level traversable](#)<sup>p990</sup>.
3. Let *navigables* be the [inclusive descendant navigables](#)<sup>p994</sup> of *top*'s [active document](#)<sup>p989</sup>.
4. Let *windows* be the list of [Window](#)<sup>p922</sup> objects constructed by taking the [active window](#)<sup>p989</sup> of each item in *navigables*.
5. **For each** *window* in *windows*, set *window*'s [last history-action activation timestamp](#)<sup>p829</sup> to *window*'s [last activation timestamp](#)<sup>p829</sup>.

#### Note

Note the asymmetry in the sets of [browsing contexts](#)<sup>p998</sup> in the page that are affected by an [activation notification](#)<sup>p830</sup> vs an [activation consumption](#)<sup>p831</sup>: an activation consumption changes (to false) the [transient activation](#)<sup>p830</sup> states for all browsing contexts in the page, but an activation notification changes (to true) the states for a subset of those browsing contexts. The exhaustive nature of consumption here is deliberate: it prevents malicious sites from making multiple calls to an [activation consuming API](#)<sup>p831</sup> from a single user activation (possibly by exploiting a deep hierarchy of [iframe](#)<sup>p390</sup>s).

### 6.4.3 APIs gated by user activation § p831

APIs that are dependent on user activation are classified into different levels:

#### Sticky activation-gated APIs

These APIs require the [sticky activation](#)<sup>p830</sup> state to be true, so they are blocked until the very first user activation.

#### Transient activation-gated APIs

These APIs require the [transient activation](#)<sup>p830</sup> state to be true, but they don't [consume](#)<sup>p831</sup> it, so multiple calls are allowed per user activation until the transient state [expires](#)<sup>p830</sup>.

#### Transient activation-consuming APIs

These APIs require the [transient activation](#)<sup>p830</sup> state to be true, and they [consume user activation](#)<sup>p831</sup> in each call to prevent multiple calls per user activation.

#### History-action activation-consuming APIs

These APIs require the [history-action activation](#)<sup>p830</sup> state to be true, and they [consume history-action user activation](#)<sup>p831</sup> in each call

to prevent multiple calls per user activation.

6.4.4 The **UserActivation**<sup>p832</sup> interface §<sup>p83</sup><sub>2</sub>

Each **Window**<sup>p922</sup> has an **associated UserActivation**, which is a **UserActivation**<sup>p832</sup> object. Upon creation of the **Window**<sup>p922</sup> object, its **associated UserActivation**<sup>p832</sup> must be set to a **new UserActivation**<sup>p832</sup> object created in the **Window**<sup>p922</sup> object's **relevant realm**<sup>p1083</sup>.

IDL

```
[Exposed=Window]
interface UserActivation {
  readonly attribute boolean hasBeenActive;
  readonly attribute boolean isActive;
};

partial interface Navigator {
  [SameObject] readonly attribute UserActivation userActivation;
};
```

For web developers (non-normative)

**navigator**<sup>p1170</sup>.**userActivation**<sup>p832</sup>.**hasBeenActive**<sup>p832</sup>  
Returns whether the window has **sticky activation**<sup>p830</sup>.

**navigator**<sup>p1170</sup>.**userActivation**<sup>p832</sup>.**isActive**<sup>p832</sup>  
Returns whether the window has **transient activation**<sup>p830</sup>.

The **userActivation** getter steps are to return **this**'s **relevant global object**<sup>p1083</sup>'s **associated UserActivation**<sup>p832</sup>.

The **hasBeenActive** getter steps are to return true if **this**'s **relevant global object**<sup>p1083</sup> has **sticky activation**<sup>p830</sup>, and false otherwise.

The **isActive** getter steps are to return true if **this**'s **relevant global object**<sup>p1083</sup> has **transient activation**<sup>p830</sup>, and false otherwise.

6.4.5 User agent automation §<sup>p83</sup><sub>2</sub>

For the purposes of user-agent automation and application testing, this specification defines the following **extension command** for the *Web Driver* specification. It is optional for a user agent to support the following **extension command**. **[WEBDRIVER]**<sup>p1483</sup>

HTTP Method	URI Template
POST	/session/{session id}/window/consume-user-activation

The **remote end steps** are:

- Let *window* be **current browsing context**'s **active window**<sup>p998</sup>.
- Let *consume* be true if *window* has **transient activation**<sup>p830</sup>; otherwise false.
- If *consume* is true, then **consume user activation**<sup>p831</sup> of *window*.
- Return **success** with data *consume*.

6.5 Activation behavior of elements §<sup>p83</sup><sub>2</sub>

Certain elements in HTML have an **activation behavior**, which means that the user can activate them. This is always caused by a **click** event.

The user agent should allow the user to manually trigger elements that have an **activation behavior**, for instance using keyboard or voice input, or through mouse clicks. When the user triggers an element with a defined **activation behavior** in a manner other than

clicking it, the default action of the interaction event must be to [fire a click event](#)<sup>p1148</sup> at the element.

For web developers (non-normative)

**`element.click`**<sup>p833</sup>()

Acts as if the element was clicked.

Each element has an associated **click in progress flag**, which is initially unset.

The **`click()`** method must run the following steps:

1. If this element is a form control that is [disabled](#)<sup>p601</sup>, then return.
2. If this element's [click in progress flag](#)<sup>p833</sup> is set, then return.
3. Set this element's [click in progress flag](#)<sup>p833</sup>.
4. [Fire a synthetic pointer event](#)<sup>p1147</sup> named **click** at this element, with the *not trusted flag* set.
5. Unset this element's [click in progress flag](#)<sup>p833</sup>.

### 6.5.1 The **`ToggleEvent`**<sup>p833</sup> interface §<sup>p83</sup><sub>3</sub>

IDL [Exposed=Window]

```
interface ToggleEvent : Event {
  constructor(DOMString type, optional ToggleEventInit eventInitDict = {});
  readonly attribute DOMString oldState;
  readonly attribute DOMString newState;
};

dictionary ToggleEventInit : EventInit {
  DOMString oldState = "";
  DOMString newState = "";
};
```

For web developers (non-normative)

**`event.oldState`**<sup>p833</sup>

Set to "closed" when transitioning from closed to open, or set to "open" when transitioning from open to closed.

**`event.newState`**<sup>p833</sup>

Set to "open" when transitioning from closed to open, or set to "closed" when transitioning from open to closed.

The **oldState** and **newState** attributes must return the values they are initialized to.

A **toggle task tracker** is a [struct](#) which has:

**task**

A [task](#)<sup>p1124</sup> which fires a **`ToggleEvent`**<sup>p833</sup>.

**old state**

A string which represents the [task](#)<sup>p833</sup>'s event's value for the **oldState**<sup>p833</sup> attribute.

## 6.6 Focus §<sup>p83</sup><sub>3</sub>

### 6.6.1 Introduction §<sup>p83</sup><sub>3</sub>

*This section is non-normative.*

An HTML user interface typically consists of multiple interactive widgets, such as form controls, scrollable regions, links, dialog boxes,

browser tabs, and so forth. These widgets form a hierarchy, with some (e.g. browser tabs, dialog boxes) containing others (e.g. links, form controls).

When interacting with an interface using a keyboard, key input is channeled from the system, through the hierarchy of interactive widgets, to an active widget, which is said to be [focused](#)<sup>p836</sup>.

#### Example

Consider an HTML application running in a browser tab running in a graphical environment. Suppose this application had a page with some text controls and links, and was currently showing a modal dialog, which itself had a text control and a button.

The hierarchy of focusable widgets, in this scenario, would include the browser window, which would have, amongst its children, the browser tab containing the HTML application. The tab itself would have as its children the various links and text controls, as well as the dialog. The dialog itself would have as its children the text control and the button.

If the widget with [focus](#)<sup>p836</sup> in this example was the text control in the dialog box, then key input would be channeled from the graphical system to ① the web browser, then to ② the tab, then to ③ the dialog, and finally to ④ the text control.

Keyboard events are always targeted at this [focused](#)<sup>p836</sup> element.

#### 6.6.2 Data model §<sup>p83</sup><sub>4</sub>

A [top-level traversable](#)<sup>p990</sup> has **system focus** when it can receive keyboard input channeled from the operating system, possibly targeted at one of its [active document](#)<sup>p989</sup>'s [descendant navigables](#)<sup>p994</sup>.

A [top-level traversable](#)<sup>p990</sup> has **user attention** when its [system visibility state](#)<sup>p990</sup> is "visible", and it either has [system focus](#)<sup>p834</sup> or user agent widgets directly related to it can receive keyboard input channeled from the operating system.

#### Note

*User attention is lost when a browser window loses focus, whereas system focus might also be lost to other system widgets in the browser window such as a location bar.*

A [Document](#)<sup>p130</sup> *d* is a **fully active descendant of a top-level traversable with user attention** when *d* is [fully active](#)<sup>p1003</sup> and *d*'s [node navigable](#)<sup>p989</sup>'s [top-level traversable](#)<sup>p990</sup> has [user attention](#)<sup>p834</sup>.

The term **focusable area** is used to refer to regions of the interface that can further become the target of such keyboard input. Focusable areas can be elements, parts of elements, or other regions managed by the user agent.

Each [focusable area](#)<sup>p835</sup> has a **DOM anchor**, which is a [Node](#) object that represents the position of the [focusable area](#)<sup>p835</sup> in the DOM. (When the [focusable area](#)<sup>p835</sup> is itself a [Node](#), it is its own [DOM anchor](#)<sup>p835</sup>.) The [DOM anchor](#)<sup>p835</sup> is used in some APIs as a substitute for the [focusable area](#)<sup>p835</sup> when there is no other DOM object to represent the [focusable area](#)<sup>p835</sup>.

The following table describes what objects can be [focusable areas](#)<sup>p835</sup>. The cells in the left column describe objects that can be [focusable areas](#)<sup>p835</sup>; the cells in the right column describe the [DOM anchors](#)<sup>p835</sup> for those elements. (The cells that span both columns are non-normative examples.)

<a href="#">Focusable area</a> <sup>p835</sup>	<a href="#">DOM anchor</a> <sup>p835</sup>
Examples	
<b>Elements that meet all the following criteria:</b> <ul style="list-style-type: none"><li>the element's <a href="#">tabindex value</a><sup>p839</sup> is non-null, or the element is determined by the user agent to be focusable;</li><li>the element is either not a <a href="#">shadow host</a>, or has a <a href="#">shadow root</a> whose <a href="#">delegates focus</a> is false;</li><li>the element is not <a href="#">actually disabled</a><sup>p781</sup>;</li><li>the element is not <a href="#">inert</a><sup>p827</sup>;</li><li>the element is either <a href="#">being rendered</a><sup>p1388</sup>, <a href="#">delegating its rendering to its children</a><sup>p1388</sup>, or <a href="#">being used as relevant canvas fallback content</a><sup>p678</sup>.</li></ul>	The element itself.
<b>Example</b> <a href="#">iframe</a> <sup>p390</sup> , <a href="#">dialog</a> <sup>p646</sup> , <a href="#">&lt;input type=</a> <a href="#">text</a> <a href="#">&gt;</a> <sup>p527</sup> , sometimes <a href="#">&lt;a href=</a> <a href="#">" "&gt;</a> <sup>p257</sup> (depending on platform conventions).	
<b>The shapes of <a href="#">area</a><sup>p471</sup> elements in an <a href="#">image map</a><sup>p473</sup> associated with an <a href="#">img</a><sup>p346</sup> element that is <a href="#">being rendered</a><sup>p1388</sup> and is not <a href="#">inert</a><sup>p827</sup>.</b>	The <a href="#">img</a> <sup>p346</sup> element.
<b>Example</b> In the following example, the <a href="#">area</a> <sup>p471</sup> element creates two shapes, one on each image. The <a href="#">DOM anchor</a> <sup>p835</sup> of the first shape is the first <a href="#">img</a> <sup>p346</sup> element, and the <a href="#">DOM anchor</a> <sup>p835</sup> of the second shape is the second <a href="#">img</a> <sup>p346</sup> element. <pre>&lt;map id=wallmap&gt;&lt;area alt="Enter Door" coords="10,10,100,200" href="door.html"&gt;&lt;/map&gt; ... &lt;img src="images/innerwall.jpeg" alt="There is a white wall here, with a door." usemap="#wallmap"&gt; ... &lt;img src="images/outerwall.jpeg" alt="There is a red wall here, with a door." usemap="#wallmap"&gt;</pre>	
<b>The user-agent provided subwidgets of elements that are <a href="#">being rendered</a><sup>p1388</sup> and are not <a href="#">actually disabled</a><sup>p781</sup> or <a href="#">inert</a><sup>p827</sup>.</b>	The element for which the <a href="#">focusable area</a> <sup>p835</sup> is a subwidget.
<b>Example</b> The <a href="#">controls in the user interface</a> <sup>p464</sup> for a <a href="#">video</a> <sup>p406</sup> element, the up and down buttons in a spin-control version of <a href="#">&lt;input type=</a> <a href="#">number</a> <a href="#">&gt;</a> <sup>p537</sup> , the part of a <a href="#">details</a> <sup>p637</sup> element's rendering that enables the element to be opened or closed using keyboard input.	
<b>The scrollable regions of elements that are <a href="#">being rendered</a><sup>p1388</sup> and are not <a href="#">inert</a><sup>p827</sup>.</b>	The element for which the box that the scrollable region scrolls was created.
<b>Example</b> The CSS <a href="#">'overflow'</a> property's 'scroll' value typically creates a scrollable region.	
<b>The <a href="#">viewport</a> of a <a href="#">Document</a><sup>p130</sup> that has a non-null <a href="#">browsing context</a><sup>p999</sup> and is not <a href="#">inert</a><sup>p827</sup>.</b>	The <a href="#">Document</a> <sup>p130</sup> for which the <a href="#">viewport</a> was created.
<b>Example</b> The contents of an <a href="#">iframe</a> <sup>p390</sup> .	
<b>Any other element or part of an element determined by the user agent to be a focusable area, especially to aid with accessibility or to better match platform conventions.</b>	The element.

<a href="#">Focusable area</a> <sup>p835</sup>	<a href="#">DOM anchor</a> <sup>p835</sup>
Examples	
<p><b>Example</b></p> <p>A user agent could make all list item bullets <a href="#">sequentially focusable</a><sup>p837</sup>, so that a user can more easily navigate lists.</p>	
<p><b>Example</b></p> <p>Similarly, a user agent could make all elements with <a href="#">title</a><sup>p157</sup> attributes <a href="#">sequentially focusable</a><sup>p837</sup>, so that their advisory information can be accessed.</p>	

**Note**

A [navigable container](#)<sup>p991</sup> (e.g. an [iframe](#)<sup>p390</sup>) is a [focusable area](#)<sup>p835</sup>, but key events routed to a [navigable container](#)<sup>p991</sup> get immediately routed to its [content navigable](#)<sup>p991</sup>'s [active document](#)<sup>p989</sup>. Similarly, in sequential focus navigation a [navigable container](#)<sup>p991</sup> essentially acts merely as a placeholder for its [content navigable](#)<sup>p991</sup>'s [active document](#)<sup>p989</sup>.

One [focusable area](#)<sup>p835</sup> in each [Document](#)<sup>p130</sup> is designated the **focused area of the document**. Which control is so designated changes over time, based on algorithms in this specification.

**Note**

Even if a document is not [fully active](#)<sup>p1003</sup> and not shown to the user, it can still have a [focused area of the document](#)<sup>p836</sup>. If a document's [fully active](#)<sup>p1003</sup> state changes, its [focused area of the document](#)<sup>p836</sup> will stay the same.

The **currently focused area of a top-level traversable** *traversable* is the [focusable area](#)<sup>p835</sup>-or-null returned by this algorithm:

1. If *traversable* does not have [system focus](#)<sup>p834</sup>, then return null.
2. Let *candidate* be *traversable*'s [active document](#)<sup>p989</sup>.
3. While *candidate*'s [focused area](#)<sup>p836</sup> is a [navigable container](#)<sup>p991</sup> with a non-null [content navigable](#)<sup>p991</sup>: set *candidate* to the [active document](#)<sup>p989</sup> of that [navigable container](#)<sup>p991</sup>'s [content navigable](#)<sup>p991</sup>.
4. If *candidate*'s [focused area](#)<sup>p836</sup> is non-null, set *candidate* to *candidate*'s [focused area](#)<sup>p836</sup>.
5. Return *candidate*.

The **current focus chain of a top-level traversable** *traversable* is the [focus chain](#)<sup>p836</sup> of the [currently focused area](#)<sup>p836</sup> of *traversable*, if *traversable* is non-null, or an empty list otherwise.

An element that is the [DOM anchor](#)<sup>p835</sup> of a [focusable area](#)<sup>p835</sup> is said to **gain focus** when that [focusable area](#)<sup>p835</sup> becomes the [currently focused area of a top-level traversable](#)<sup>p836</sup>. When an element is the [DOM anchor](#)<sup>p835</sup> of a [focusable area](#)<sup>p835</sup> of the [currently focused area of a top-level traversable](#)<sup>p836</sup>, it is **focused**.

The **focus chain** of a [focusable area](#)<sup>p835</sup> *subject* is the ordered list constructed as follows:

1. Let *output* be an empty [list](#).
2. Let *currentObject* be *subject*.
3. While true:
  1. [Append](#) *currentObject* to *output*.
  2. If *currentObject* is an [area](#)<sup>p471</sup> element's shape, then [append](#) that [area](#)<sup>p471</sup> element to *output*.  
Otherwise, if *currentObject*'s [DOM anchor](#)<sup>p835</sup> is an element that is not *currentObject* itself, then [append](#) *currentObject*'s [DOM anchor](#)<sup>p835</sup> to *output*.
  3. If *currentObject* is a [focusable area](#)<sup>p835</sup>, then set *currentObject* to *currentObject*'s [DOM anchor](#)<sup>p835</sup>'s [node document](#).  
Otherwise, if *currentObject* is a [Document](#)<sup>p130</sup> whose [node navigable](#)<sup>p989</sup>'s [parent](#)<sup>p989</sup> is non-null, then set *currentObject* to *currentObject*'s [node navigable](#)<sup>p989</sup>'s [parent](#)<sup>p989</sup>.  
Otherwise, [break](#).

#### 4. Return output.

##### Note

The chain starts with subject and (if subject is or can be the [currently focused area of a top-level traversable](#)<sup>p836</sup>) continues up the focus hierarchy up to the [Document](#)<sup>p130</sup> of the [top-level traversable](#)<sup>p990</sup>.

All elements that are [focusable areas](#)<sup>p835</sup> are said to be **focusable**.

There are two special types of focusability for [focusable areas](#)<sup>p835</sup>:

- A [focusable area](#)<sup>p835</sup> is said to be **sequentially focusable** if it is included in its [Document](#)<sup>p130</sup>'s [sequential focus navigation order](#)<sup>p844</sup> and the user agent determines that it is sequentially focusable.
- A [focusable area](#)<sup>p835</sup> is said to be **click focusable** if the user agent determines that it is click focusable. User agents should consider focusable areas with non-null [tabindex values](#)<sup>p839</sup> to be click focusable.

##### Note

Elements which are not [focusable](#)<sup>p837</sup> are not [focusable areas](#)<sup>p835</sup>, and thus not [sequentially focusable](#)<sup>p837</sup> and not [click focusable](#)<sup>p837</sup>.

##### Note

Being [focusable](#)<sup>p837</sup> is a statement about whether an element can be focused programmatically, e.g. via the [focus\(\)](#)<sup>p847</sup> method or [autofocus](#)<sup>p848</sup> attribute. In contrast, [sequentially focusable](#)<sup>p837</sup> and [click focusable](#)<sup>p837</sup> govern how the user agent responds to user interaction: respectively, to [sequential focus navigation](#)<sup>p844</sup> and as [activation behavior](#)<sup>p0</sup>.

The user agent might determine that an element is not [sequentially focusable](#)<sup>p837</sup> even if it is [focusable](#)<sup>p837</sup> and is included in its [Document](#)<sup>p130</sup>'s [sequential focus navigation order](#)<sup>p844</sup>, according to user preferences. For example, macOS users can set the user agent to skip non-form control elements, or can skip links when doing [sequential focus navigation](#)<sup>p844</sup> with just the Tab key (as opposed to using both the Option and Tab keys).

Similarly, the user agent might determine that an element is not [click focusable](#)<sup>p837</sup> even if it is [focusable](#)<sup>p837</sup>. For example, in some user agents, clicking on a non-editable form control does not focus it, i.e. the user agent has determined that such controls are not click focusable.

Thus, an element can be [focusable](#)<sup>p837</sup>, but neither [sequentially focusable](#)<sup>p837</sup> nor [click focusable](#)<sup>p837</sup>. For example, in some user agents, a non-editable form-control with a negative-integer [tabindex value](#)<sup>p839</sup> would not be focusable via user interaction, only via programmatic APIs.

When a user [activates](#)<sup>p832</sup> a [click focusable](#)<sup>p837</sup> [focusable area](#)<sup>p835</sup>, the user agent must run the [focusing steps](#)<sup>p842</sup> on the [focusable area](#)<sup>p835</sup> with *focus trigger* set to "click".

##### Note

Note that focusing is not an [activation behavior](#), i.e. calling the [click\(\)](#)<sup>p833</sup> method on an element or dispatching a synthetic [click](#) event on it won't cause the element to get focused.

A node is a **focus navigation scope owner** if it is a [Document](#)<sup>p130</sup>, a [shadow host](#), a [slot](#)<sup>p675</sup>, or an element in the [popover showing state](#)<sup>p887</sup> which also has a [popover invoker](#)<sup>p887</sup> set.

Each [focus navigation scope owner](#)<sup>p837</sup> has a **focus navigation scope**, which is a list of elements. Its contents are determined as follows:

Every element *element* has an **associated focus navigation owner**, which is either null or a [focus navigation scope owner](#)<sup>p837</sup>. It is determined by the following algorithm:

1. If *element*'s parent is null, then return null.
2. If *element*'s parent is a [shadow host](#), then return *element*'s [assigned slot](#).
3. If *element*'s parent is a [shadow root](#), then return the parent's [host](#).
4. If *element*'s parent is the [document element](#), then return the parent's [node document](#).

5. If *element* is in the [popover showing state](#)<sup>p887</sup> and has a [popover invoker](#)<sup>p887</sup> set, then return *element*.
6. Return *element*'s parent's [associated focus navigation owner](#)<sup>p837</sup>.

Then, the contents of a given [focus navigation scope owner](#)<sup>p837</sup> owner's [focus navigation scope](#)<sup>p837</sup> are all elements whose [associated focus navigation owner](#)<sup>p837</sup> is owner.

#### Note

*The order of elements within a [focus navigation scope](#)<sup>p837</sup> does not impact any of the algorithms in this specification. Ordering only becomes important for the [tabindex-ordered focus navigation scope](#)<sup>p838</sup> and [flattened tabindex-ordered focus navigation scope](#)<sup>p838</sup> concepts defined below.*

A **tabindex-ordered focus navigation scope** is a list of [focusable areas](#)<sup>p835</sup> and [focus navigation scope owners](#)<sup>p837</sup>. Every [focus navigation scope owner](#)<sup>p837</sup> owner has [tabindex-ordered focus navigation scope](#)<sup>p838</sup>, whose contents are determined as follows:

- It contains all elements in owner's [focus navigation scope](#)<sup>p837</sup> that are themselves [focus navigation scope owners](#)<sup>p837</sup>, except the elements whose [tabindex value](#)<sup>p839</sup> is a negative integer.
- It contains all of the [focusable areas](#)<sup>p835</sup> whose [DOM anchor](#)<sup>p835</sup> is an element in owner's [focus navigation scope](#)<sup>p837</sup>, except the [focusable areas](#)<sup>p835</sup> whose [tabindex value](#)<sup>p839</sup> is a negative integer.

The order within a [tabindex-ordered focus navigation scope](#)<sup>p838</sup> is determined by each element's [tabindex value](#)<sup>p839</sup>, as described in the section below.

#### Note

*The rules there do not give a precise ordering, as they are composed mostly of "should" statements and relative orderings.*

A **flattened tabindex-ordered focus navigation scope** is a list of [focusable areas](#)<sup>p835</sup>. Every [focus navigation scope owner](#)<sup>p837</sup> owner owns a distinct [flattened tabindex-ordered focus navigation scope](#)<sup>p838</sup>, whose contents are determined by the following algorithm:

1. Let *result* be a [clone](#) of owner's [tabindex-ordered focus navigation scope](#)<sup>p838</sup>.
2. For each *item* of *result*:
  1. If *item* is not a [focus navigation scope owner](#)<sup>p837</sup>, then [continue](#).
  2. If *item* is not a [focusable area](#)<sup>p835</sup>, then replace *item* with all of the items in *item*'s [flattened tabindex-ordered focus navigation scope](#)<sup>p838</sup>.
  3. Otherwise, insert the contents of *item*'s [flattened tabindex-ordered focus navigation scope](#)<sup>p838</sup> after *item*.

### 6.6.3 The [tabindex](#)<sup>p838</sup> attribute § <sup>p83</sup> 8

The **tabindex** content attribute allows authors to make an element and regions that have the element as its [DOM anchor](#)<sup>p835</sup> be [focusable areas](#)<sup>p835</sup>, allow or prevent them from being [sequentially focusable](#)<sup>p837</sup>, and determine their relative ordering for [sequential focus navigation](#)<sup>p844</sup>. MDN

The name "tab index" comes from the common use of the Tab key to navigate through the focusable elements. The term "tabbing" refers to moving forward through [sequentially focusable](#)<sup>p837</sup> [focusable areas](#)<sup>p835</sup>.

The [tabindex](#)<sup>p838</sup> attribute, if specified, must have a value that is a [valid integer](#)<sup>p76</sup>. Positive numbers specify the relative position of the element's [focusable areas](#)<sup>p835</sup> in the [sequential focus navigation order](#)<sup>p844</sup>, and negative numbers indicate that the control is not [sequentially focusable](#)<sup>p837</sup>.

Developers should use caution when using values other than 0 or −1 for their [tabindex](#)<sup>p838</sup> attributes as this is complicated to do correctly.

#### Note

*The following provides a non-normative summary of the behaviors of the possible [tabindex](#)<sup>p838</sup> attribute values. The below*

processing model gives the more precise rules.

### omitted (or non-integer values)

The user agent will decide whether the element is [focusable](#)<sup>p837</sup>, and if it is, whether it is [sequentially focusable](#)<sup>p837</sup> or [click focusable](#)<sup>p837</sup> (or both).

### –1 (or other negative integer values)

Causes the element to be [focusable](#)<sup>p837</sup>, and indicates that the author would prefer the element to be [click focusable](#)<sup>p837</sup> but not [sequentially focusable](#)<sup>p837</sup>. The user agent might ignore this preference for click and sequential focusability, e.g., for specific element types according to platform conventions, or for keyboard-only users.

### 0

Causes the element to be [focusable](#)<sup>p837</sup>, and indicates that the author would prefer the element to be both [click focusable](#)<sup>p837</sup> and [sequentially focusable](#)<sup>p837</sup>. The user agent might ignore this preference for click and sequential focusability.

### positive integer values

Behaves the same as 0, but in addition creates a relative ordering within a [tabindex-ordered focus navigation scope](#)<sup>p838</sup>, so that elements with higher [tabindex](#)<sup>p838</sup> attribute value come later.

Note that the [tabindex](#)<sup>p838</sup> attribute cannot be used to make an element non-focusable. The only way a page author can do that is by [disabling](#)<sup>p781</sup> the element, or making it [inert](#)<sup>p827</sup>.

The **tabindex value** of an element is the value of its [tabindex](#)<sup>p838</sup> attribute, parsed using the [rules for parsing integers](#)<sup>p76</sup>. If parsing fails or the attribute is not specified, then the [tabindex value](#)<sup>p839</sup> is null.

The [tabindex value](#)<sup>p839</sup> of a [focusable area](#)<sup>p835</sup> is the [tabindex value](#)<sup>p839</sup> of its [DOM anchor](#)<sup>p835</sup>.

The [tabindex value](#)<sup>p839</sup> of an element must be interpreted as follows:

### If the value is null

The user agent should follow platform conventions to determine if the element should be considered as a [focusable area](#)<sup>p835</sup> and if so, whether the element and any [focusable areas](#)<sup>p835</sup> that have the element as their [DOM anchor](#)<sup>p835</sup> are [sequentially focusable](#)<sup>p837</sup>, and if so, what their relative position in their [tabindex-ordered focus navigation scope](#)<sup>p838</sup> is to be. If the element is a [focus navigation scope owner](#)<sup>p837</sup>, it must be included in its [tabindex-ordered focus navigation scope](#)<sup>p838</sup> even if it is not a [focusable area](#)<sup>p835</sup>.

The relative ordering within a [tabindex-ordered focus navigation scope](#)<sup>p838</sup> for elements and [focusable areas](#)<sup>p835</sup> that belong to the same [focus navigation scope](#)<sup>p837</sup> and whose [tabindex value](#)<sup>p839</sup> is null should be in [shadow-including tree order](#).

Modulo platform conventions, it is suggested that the following elements should be considered as [focusable areas](#)<sup>p835</sup> and be [sequentially focusable](#)<sup>p837</sup>:

- [a](#)<sup>p257</sup> elements that have an [href](#)<sup>p303</sup> attribute
- [button](#)<sup>p566</sup> elements
- [input](#)<sup>p520</sup> elements whose [type](#)<sup>p523</sup> attribute are not in the [Hidden](#)<sup>p527</sup> state
- [select](#)<sup>p568</sup> elements
- [textarea](#)<sup>p579</sup> elements
- [summary](#)<sup>p643</sup> elements that are the first [summary](#)<sup>p643</sup> element child of a [details](#)<sup>p637</sup> element
- Elements with a [draggable](#)<sup>p885</sup> attribute set, if that would enable the user agent to allow the user to begin drag operations for those elements without the use of a pointing device
- [Editing hosts](#)<sup>p855</sup>
- [Navigable containers](#)<sup>p991</sup>

### If the value is a negative integer

The user agent must consider the element as a [focusable area](#)<sup>p835</sup>, but should omit the element from any [tabindex-ordered focus navigation scope](#)<sup>p838</sup>.

## Note

One valid reason to ignore the requirement that sequential focus navigation not allow the author to lead to the element would be if the user's only mechanism for moving the focus is sequential focus navigation. For instance, a keyboard-only user would be unable to click on a text control with a negative `tabindex`<sup>p838</sup>, so that user's user agent would be well justified in allowing the user to tab to the control regardless.

### If the value is a zero

The user agent must allow the element to be considered as a [focusable area](#)<sup>p835</sup> and should allow the element and any [focusable areas](#)<sup>p835</sup> that have the element as their [DOM anchor](#)<sup>p835</sup> to be [sequentially focusable](#)<sup>p837</sup>.

The relative ordering within a [tabindex-ordered focus navigation scope](#)<sup>p838</sup> for elements and [focusable areas](#)<sup>p835</sup> that belong to the same [focus navigation scope](#)<sup>p837</sup> and whose [tabindex value](#)<sup>p839</sup> is zero should be in [shadow-including tree order](#).

### If the value is greater than zero

The user agent must allow the element to be considered as a [focusable area](#)<sup>p835</sup> and should allow the element and any [focusable areas](#)<sup>p835</sup> that have the element as their [DOM anchor](#)<sup>p835</sup> to be [sequentially focusable](#)<sup>p837</sup>, and should place the element — referenced as *candidate* below — and the aforementioned [focusable areas](#)<sup>p835</sup> in the [tabindex-ordered focus navigation scope](#)<sup>p838</sup> where the element is a part of so that, relative to other elements and [focusable areas](#)<sup>p835</sup> that belong to the same [focus navigation scope](#)<sup>p837</sup>, they are:

- before any [focusable area](#)<sup>p835</sup> whose [DOM anchor](#)<sup>p835</sup> is an element whose [tabindex](#)<sup>p838</sup> attribute has been omitted or whose value, when parsed, returns an error,
- before any [focusable area](#)<sup>p835</sup> whose [DOM anchor](#)<sup>p835</sup> is an element whose [tabindex](#)<sup>p838</sup> attribute has a value less than or equal to zero,
- after any [focusable area](#)<sup>p835</sup> whose [DOM anchor](#)<sup>p835</sup> is an element whose [tabindex](#)<sup>p838</sup> attribute has a value greater than zero but less than the value of the [tabindex](#)<sup>p838</sup> attribute on *candidate*,
- after any [focusable area](#)<sup>p835</sup> whose [DOM anchor](#)<sup>p835</sup> is an element whose [tabindex](#)<sup>p838</sup> attribute has a value equal to the value of the [tabindex](#)<sup>p838</sup> attribute on *candidate* but that is located earlier than *candidate* in [shadow-including tree order](#),
- before any [focusable area](#)<sup>p835</sup> whose [DOM anchor](#)<sup>p835</sup> is an element whose [tabindex](#)<sup>p838</sup> attribute has a value equal to the value of the [tabindex](#)<sup>p838</sup> attribute on *candidate* but that is located later than *candidate* in [shadow-including tree order](#), and
- before any [focusable area](#)<sup>p835</sup> whose [DOM anchor](#)<sup>p835</sup> is an element whose [tabindex](#)<sup>p838</sup> attribute has a value greater than the value of the [tabindex](#)<sup>p838</sup> attribute on *candidate*.

The [tabIndex](#) IDL attribute must [reflect](#)<sup>p104</sup> the value of the [tabindex](#)<sup>p838</sup> content attribute. The [default value](#)<sup>p106</sup> is 0 if the element is an [a](#)<sup>p257</sup>, [area](#)<sup>p471</sup>, [button](#)<sup>p566</sup>, [frame](#)<sup>p1433</sup>, [iframe](#)<sup>p390</sup>, [input](#)<sup>p520</sup>, [object](#)<sup>p402</sup>, [select](#)<sup>p568</sup>, [textarea](#)<sup>p579</sup>, or [SVG a](#) element, or is a [summary](#)<sup>p643</sup> element that is a [summary for its parent details](#)<sup>p643</sup>. The [default value](#)<sup>p106</sup> is −1 otherwise.

## Note

The varying default value based on element type is a historical artifact.

### 6.6.4 Processing model <sup>p84</sup><sub>0</sub>

To **get the focusable area** for a *focus target* that is either an element that is not a [focusable area](#)<sup>p835</sup>, or is a [navigable](#)<sup>p989</sup>, given an optional string *focus trigger* (default "other"), run the first matching set of steps from the following list:

↪ If *focus target* is an [area](#)<sup>p471</sup> element with one or more shapes that are [focusable areas](#)<sup>p835</sup>

Return the shape corresponding to the first [img](#)<sup>p346</sup> element in [tree order](#) that uses the image map to which the [area](#)<sup>p471</sup> element belongs.

↪ If *focus target* is an element with one or more scrollable regions that are [focusable areas](#)<sup>p835</sup>

Return the element's first scrollable region, according to a pre-order, depth-first traversal of the [flat tree](#). [\[CSSSCOPING\]](#)<sup>p1477</sup>

↪ If *focus target* is the [document element](#) of its [Document](#)<sup>p130</sup>

Return the [Document](#)<sup>p130</sup>'s [viewport](#).

↪ If **focus target** is a [navigable](#)<sup>p989</sup>

Return the [navigable](#)<sup>p989</sup>'s [active document](#)<sup>p989</sup>.

↪ If **focus target** is a [navigable container](#)<sup>p991</sup> with a non-null [content navigable](#)<sup>p991</sup>

Return the [navigable container](#)<sup>p991</sup>'s [content navigable](#)<sup>p991</sup>'s [active document](#)<sup>p989</sup>.

↪ If **focus target** is a [shadow host](#) whose [shadow root](#)'s [delegates focus](#) is true

1. Let *focusedElement* be the [currently focused area of a top-level traversable](#)<sup>p836</sup>'s [DOM anchor](#)<sup>p835</sup>.
2. If *focus target* is a [shadow-including inclusive ancestor](#) of *focusedElement*, then return *focusedElement*.
3. Return the [focus delegate](#)<sup>p841</sup> for *focus target* given *focus trigger*.

#### Note

For [sequential focusability](#)<sup>p837</sup>, the handling of [shadow hosts](#) and [delegates focus](#) is done when constructing the [sequential focus navigation order](#)<sup>p844</sup>. That is, the [focusing steps](#)<sup>p842</sup> will never be called on such [shadow hosts](#) as part of sequential focus navigation.

↪ Otherwise

Return null.

The **focus delegate** for a *focusTarget*, given an optional string *focusTrigger* (default "other"), is given by the following steps:

1. If *focusTarget* is a [shadow host](#) and its [shadow root](#)'s [delegates focus](#) is false, then return null.
2. Let *whereToLook* be *focusTarget*.
3. If *whereToLook* is a [shadow host](#), then set *whereToLook* to *whereToLook*'s [shadow root](#).
4. Let *autofocusDelegate* be the [autofocus delegate](#)<sup>p841</sup> for *whereToLook* given *focusTrigger*.
5. If *autofocusDelegate* is not null, then return *autofocusDelegate*.
6. For each descendant of *whereToLook*'s [descendants](#), in [tree order](#):
  1. Let *focusableArea* be null.
  2. If *focusTarget* is a [dialog](#)<sup>p646</sup> element and descendant is [sequentially focusable](#)<sup>p837</sup>, then set *focusableArea* to descendant.
  3. Otherwise, if *focusTarget* is not a [dialog](#)<sup>p646</sup> and descendant is a [focusable area](#)<sup>p835</sup>, set *focusableArea* to descendant.
  4. Otherwise, set *focusableArea* to the result of [getting the focusable area](#)<sup>p840</sup> for descendant given *focusTrigger*.

#### Note

This step can end up recursing, i.e., the [get the focusable area](#)<sup>p840</sup> steps might return the [focus delegate](#)<sup>p841</sup> of descendant.

5. If *focusableArea* is not null, then return *focusableArea*.

#### Note

It's important that we are not looking at the [shadow-including descendants](#) here, but instead only at the [descendants](#). [Shadow hosts](#) are instead handled by the recursive case mentioned above.

7. Return null.

#### Note

The above algorithm essentially returns the first suitable [focusable area](#)<sup>p835</sup> where the path between its [DOM anchor](#)<sup>p835</sup> and *focusTarget* delegates focus at any shadow tree boundaries.

The **autofocus delegate** for a *focus target* given a *focus trigger* is given by the following steps:

1. For each [descendant](#) of *focus target*, in [tree order](#):

1. If *descendant* does not have an [autofocus<sup>p848</sup>](#) content attribute, then [continue](#).
  2. Let *focusable area* be *descendant*, if *descendant* is a [focusable area<sup>p835</sup>](#); otherwise let *focusable area* be the result of [getting the focusable area<sup>p840</sup>](#) for *descendant* given *focus trigger*.
  3. If *focusable area* is null, then [continue](#).
  4. If *focusable area* is not [click focusable<sup>p837</sup>](#) and *focus trigger* is "click", then [continue](#).
  5. Return *focusable area*.
2. Return null.

The **focusing steps** for an object *new focus target* that is either a [focusable area<sup>p835</sup>](#), or an element that is not a [focusable area<sup>p835</sup>](#), or a [navigable<sup>p989</sup>](#), are as follows. They can optionally be run with a *fallback target* and a string *focus trigger*.

1. If *new focus target* is not a [focusable area<sup>p835</sup>](#), then set *new focus target* to the result of [getting the focusable area<sup>p840</sup>](#) for *new focus target*, given *focus trigger* if it was passed.
2. If *new focus target* is null, then:
  1. If no *fallback target* was specified, then return.
  2. Otherwise, set *new focus target* to the *fallback target*.
3. If *new focus target* is a [navigable container<sup>p991</sup>](#) with non-null [content navigable<sup>p991</sup>](#), then set *new focus target* to the [content navigable<sup>p991</sup>](#)'s [active document<sup>p989</sup>](#).
4. If *new focus target* is a [focusable area<sup>p835</sup>](#) and its [DOM anchor<sup>p835</sup>](#) is [inert<sup>p827</sup>](#), then return.
5. If *new focus target* is the [currently focused area of a top-level traversable<sup>p836</sup>](#), then return.
6. Let *old chain* be the [current focus chain of the top-level traversable<sup>p836</sup>](#) in which *new focus target* finds itself.
7. Let *new chain* be the [focus chain<sup>p836</sup>](#) of *new focus target*.
8. Run the [focus update steps<sup>p843</sup>](#) with *old chain*, *new chain*, and *new focus target* respectively.

User agents must [immediately<sup>p43</sup>](#) run the [focusing steps<sup>p842</sup>](#) for a [focusable area<sup>p835</sup>](#) or [navigable<sup>p989</sup>](#) *candidate* whenever the user attempts to move the focus to *candidate*.

The **unfocusing steps** for an object *old focus target* that is either a [focusable area<sup>p835</sup>](#) or an element that is not a [focusable area<sup>p835</sup>](#) are as follows:

1. If *old focus target* is a [shadow host](#) whose [shadow root](#)'s [delegates focus](#) is true, and *old focus target*'s [shadow root](#) is a [shadow-including inclusive ancestor](#) of the [currently focused area of a top-level traversable<sup>p836</sup>](#)'s [DOM anchor<sup>p835</sup>](#), then set *old focus target* to that [currently focused area of a top-level traversable<sup>p836</sup>](#).
  2. If *old focus target* is [inert<sup>p827</sup>](#), then return.
  3. If *old focus target* is an [area<sup>p471</sup>](#) element and one of its shapes is the [currently focused area of a top-level traversable<sup>p836</sup>](#), or, if *old focus target* is an element with one or more scrollable regions, and one of them is the [currently focused area of a top-level traversable<sup>p836</sup>](#), then let *old focus target* be that [currently focused area of a top-level traversable<sup>p836</sup>](#).
  4. Let *old chain* be the [current focus chain of the top-level traversable<sup>p836</sup>](#) in which *old focus target* finds itself.
  5. If *old focus target* is not one of the entries in *old chain*, then return.
  6. If *old focus target* is not a [focusable area<sup>p835</sup>](#), then return.
  7. Let *topDocument* be *old chain*'s last entry.
  8. If *topDocument*'s [node navigable<sup>p989</sup>](#) has [system focus<sup>p834</sup>](#), then run the [focusing steps<sup>p842</sup>](#) for *topDocument*'s [viewport](#).
- Otherwise, apply any relevant platform-specific conventions for removing [system focus<sup>p834</sup>](#) from *topDocument*'s [node navigable<sup>p989</sup>](#), and run the [focus update steps<sup>p843</sup>](#) given *old chain*, an empty list, and null.

#### Note

The [unfocusing steps<sup>p842</sup>](#) do not always result in the focus changing, even when applied to the [currently focused area of a top-level](#)

[traversable<sup>p836</sup>](#). For example, if the [currently focused area of a top-level traversable<sup>p836</sup>](#) is a [viewport](#), then it will usually keep its focus regardless until another [focusable area<sup>p835</sup>](#) is explicitly focused with the [focusing steps<sup>p842</sup>](#).

The **focus update steps**, given an *old chain*, a *new chain*, and a *new focus target* respectively, are as follows:

1. If the last entry in *old chain* and the last entry in *new chain* are the same, pop the last entry from *old chain* and the last entry from *new chain* and redo this step.
2. For each entry *entry* in *old chain*, in order, run these substeps:
  1. If *entry* is an [input<sup>p520</sup>](#) element, and the [change<sup>p1471</sup>](#) event [applies<sup>p523</sup>](#) to the element, and the element does not have a defined [activation behavior](#), and the user has changed the element's [value<sup>p597</sup>](#) or its list of [selected files<sup>p544</sup>](#) while the control was focused without committing that change (such that it is different to what it was when the control was first focused), then:
    1. Set *entry*'s [user validity<sup>p597</sup>](#) to true.
    2. [Fire an event](#) named [change<sup>p1471</sup>](#) at the element, with the [bubbles](#) attribute initialized to true.
  2. If *entry* is an element, let *blur event target* be *entry*.  
If *entry* is a [Document<sup>p130</sup>](#) object, let *blur event target* be that [Document<sup>p130</sup>](#) object's [relevant global object<sup>p1083</sup>](#).  
Otherwise, let *blur event target* be null.
  3. If *entry* is the last entry in *old chain*, and *entry* is an [Element](#), and the last entry in *new chain* is also an [Element](#), then let *related blur target* be the last entry in *new chain*. Otherwise, let *related blur target* be null.
  4. If *blur event target* is not null, [fire a focus event<sup>p843</sup>](#) named [blur<sup>p1471</sup>](#) at *blur event target*, with *related blur target* as the related target.

**Note**

*In some cases, e.g., if *entry* is an [area<sup>p471</sup>](#) element's shape, a scrollable region, or a [viewport](#), no event is fired.*

3. Apply any relevant platform-specific conventions for focusing *new focus target*. (For example, some platforms select the contents of a text control when that control is focused.)
4. For each entry *entry* in *new chain*, in reverse order, run these substeps:
  1. If *entry* is a [focusable area<sup>p835</sup>](#), and the [focused area of the document<sup>p836</sup>](#) is not *entry*:
    1. Set *document*'s [relevant global object<sup>p1083</sup>](#)'s [navigation API<sup>p952</sup>](#)'s [focus changed during ongoing navigation<sup>p964</sup>](#) to true.
    2. Designate *entry* as the [focused area of the document<sup>p836</sup>](#).
  2. If *entry* is an element, let *focus event target* be *entry*.  
If *entry* is a [Document<sup>p130</sup>](#) object, let *focus event target* be that [Document<sup>p130</sup>](#) object's [relevant global object<sup>p1083</sup>](#).  
Otherwise, let *focus event target* be null.
  3. If *entry* is the last entry in *new chain*, and *entry* is an [Element](#), and the last entry in *old chain* is also an [Element](#), then let *related focus target* be the last entry in *old chain*. Otherwise, let *related focus target* be null.
  4. If *focus event target* is not null, [fire a focus event<sup>p843</sup>](#) named [focus<sup>p1471</sup>](#) at *focus event target*, with *related focus target* as the related target.

**Note**

*In some cases, e.g. if *entry* is an [area<sup>p471</sup>](#) element's shape, a scrollable region, or a [viewport](#), no event is fired.*

To **fire a focus event** named *e* at an element *t* with a given related target *r*, [fire an event](#) named *e* at *t*, using [FocusEvent](#), with the [relatedTarget](#) attribute initialized to *r*, the [view](#) attribute initialized to *t*'s [node document](#)'s [relevant global object<sup>p1083</sup>](#), and the [composed flag](#) set.

When a key event is to be routed in a [top-level traversable](#)<sup>p990</sup>, the user agent must run the following steps:

1. Let *target area* be the [currently focused area of the top-level traversable](#)<sup>p836</sup>.
2. **Assert:** *target area* is not null, since key events are only routed to [top-level traversables](#)<sup>p990</sup> that have [system focus](#)<sup>p834</sup>. Therefore, *target area* is a [focusable area](#)<sup>p835</sup>.
3. Let *target node* be *target area*'s [DOM anchor](#)<sup>p835</sup>.
4. If *target node* is a [Document](#)<sup>p130</sup> that has a [body element](#)<sup>p136</sup>, then let *target node* be [the body element](#)<sup>p136</sup> of that [Document](#)<sup>p130</sup>.  
  
Otherwise, if *target node* is a [Document](#)<sup>p130</sup> object that has a non-null [document element](#), then let *target node* be that [document element](#).
5. If *target node* is not [inert](#)<sup>p827</sup>, then:
  1. Let *canHandle* be the result of [dispatching](#) the key event at *target node*.
  2. If *canHandle* is true, then let *target area* handle the key event. This might include [firing a click event](#)<sup>p1148</sup> at *target node*.

The **has focus steps**, given a [Document](#)<sup>p130</sup> object *target*, are as follows:

1. If *target*'s [node navigable](#)<sup>p989</sup>'s [top-level traversable](#)<sup>p990</sup> does not have [system focus](#)<sup>p834</sup>, then return false.
2. Let *candidate* be *target*'s [node navigable](#)<sup>p989</sup>'s [top-level traversable](#)<sup>p990</sup>'s [active document](#)<sup>p998</sup>.
3. While true:
  1. If *candidate* is *target*, then return true.
  2. If the [focused area](#)<sup>p836</sup> of *candidate* is a [navigable container](#)<sup>p991</sup> with a non-null [content navigable](#)<sup>p991</sup>, then set *candidate* to the [active document](#)<sup>p989</sup> of that [navigable container](#)<sup>p991</sup>'s [content navigable](#)<sup>p991</sup>.
  3. Otherwise, return false.

### 6.6.5 Sequential focus navigation §<sup>p84</sup><sub>4</sub>

Each [Document](#)<sup>p130</sup> has a **sequential focus navigation order**, which orders some or all of the [focusable areas](#)<sup>p835</sup> in the [Document](#)<sup>p130</sup> relative to each other. Its contents and ordering are given by the [flattened tabindex-ordered focus navigation scope](#)<sup>p838</sup> of the [Document](#)<sup>p130</sup>.

#### Note

*Per the rules defining the [flattened tabindex-ordered focus navigation scope](#)<sup>p838</sup>, the ordering is not necessarily related to the [tree order](#) of the [Document](#)<sup>p130</sup>.*

If a [focusable area](#)<sup>p835</sup> is omitted from the [sequential focus navigation order](#)<sup>p844</sup> of its [Document](#)<sup>p130</sup>, then it is unreachable via [sequential focus navigation](#)<sup>p844</sup>.

There can also be a **sequential focus navigation starting point**. It is initially unset. The user agent may set it when the user indicates that it should be moved.

#### Example

For example, the user agent could set it to the position of the user's click if the user clicks on the document contents.

#### Note

*User agents are required to set the [sequential focus navigation starting point](#)<sup>p844</sup> to the [target element](#)<sup>p1054</sup> when navigating to a [fragment](#)<sup>p1021</sup>.*

A **sequential focus direction** is one of two possible values: "**forward**", or "**backward**". They are used in the below algorithms to

describe the direction in which sequential focus travels at the user's request.

A **selection mechanism** is one of two possible values: **"DOM"**, or **"sequential"**. They are used to describe how the [sequential navigation search algorithm](#)<sup>p845</sup> finds the [focusable area](#)<sup>p835</sup> it returns.

When the user requests that focus move from the [currently focused area of a top-level traversable](#)<sup>p836</sup> to the next or previous [focusable area](#)<sup>p835</sup> (e.g., as the default action of pressing the tab key), or when the user requests that focus sequentially move to a [top-level traversable](#)<sup>p990</sup> in the first place (e.g., from the browser's location bar), the user agent must use the following algorithm:

1. Let *starting point* be the [currently focused area of a top-level traversable](#)<sup>p836</sup>, if the user requested to move focus sequentially from there, or else the [top-level traversable](#)<sup>p990</sup> itself, if the user instead requested to move focus from outside the [top-level traversable](#)<sup>p990</sup>.
2. If there is a [sequential focus navigation starting point](#)<sup>p844</sup> defined and it is inside *starting point*, then let *starting point* be the [sequential focus navigation starting point](#)<sup>p844</sup> instead.
3. Let *direction* be **"forward"**<sup>p844</sup> if the user requested the next control, and **"backward"**<sup>p844</sup> if the user requested the previous control.

Note

Typically, pressing tab requests the next control, and pressing shift + tab requests the previous control.

4. *Loop*: Let *selection mechanism* be **"sequential"**<sup>p845</sup> if *starting point* is a [navigable](#)<sup>p989</sup> or if *starting point* is in its [Document](#)<sup>p130</sup>'s [sequential focus navigation order](#)<sup>p844</sup>.  
  
Otherwise, *starting point* is not in its [Document](#)<sup>p130</sup>'s [sequential focus navigation order](#)<sup>p844</sup>; let *selection mechanism* be **"DOM"**<sup>p845</sup>.
5. Let *candidate* be the result of running the [sequential navigation search algorithm](#)<sup>p845</sup> with *starting point*, *direction*, and *selection mechanism*.
6. If *candidate* is not null, then run the [focusing steps](#)<sup>p842</sup> for *candidate* and return.
7. Otherwise, unset the [sequential focus navigation starting point](#)<sup>p844</sup>.
8. If *starting point* is a [top-level traversable](#)<sup>p990</sup>, or a [focusable area](#)<sup>p835</sup> in the [top-level traversable](#)<sup>p990</sup>, the user agent should transfer focus to its own controls appropriately (if any), honouring *direction*, and then return.

Example

For example, if *direction* is *backward*, then the last [sequentially focusable](#)<sup>p837</sup> control before the browser's rendering area would be the control to focus.

If the user agent has no [sequentially focusable](#)<sup>p837</sup> controls — a kiosk-mode browser, for instance — then the user agent may instead restart these steps with the *starting point* being the [top-level traversable](#)<sup>p990</sup> itself.

9. Otherwise, *starting point* is a [focusable area](#)<sup>p835</sup> in a [child navigable](#)<sup>p992</sup>. Set *starting point* to that [child navigable](#)<sup>p992</sup>'s [parent](#)<sup>p989</sup> and return to the step labeled *loop*.

The **sequential navigation search algorithm**, given a [focusable area](#)<sup>p835</sup> *starting point*, [sequential focus direction](#)<sup>p844</sup> *direction*, and [selection mechanism](#)<sup>p845</sup> *selection mechanism*, consists of the following steps. They return a [focusable area](#)<sup>p835</sup>-or-null.

1. Pick the appropriate cell from the following table, and follow the instructions in that cell.

The appropriate cell is the one that is from the column whose header describes *direction* and from the first row whose header describes *starting point* and *selection mechanism*.

	<i>direction</i> is <b>"forward"</b> <sup>p844</sup>	<i>direction</i> is <b>"backward"</b> <sup>p844</sup>
<i>starting point</i> is a <a href="#">navigable</a> <sup>p989</sup>	Let <i>candidate</i> be the first <a href="#">suitable sequentially focusable area</a> <sup>p846</sup> in <i>starting point</i> 's <a href="#">active document</a> <sup>p989</sup> , if any; or else null	Let <i>candidate</i> be the last <a href="#">suitable sequentially focusable area</a> <sup>p846</sup> in <i>starting point</i> 's <a href="#">active document</a> <sup>p989</sup> , if any; or else null
<i>selection mechanism</i> is <b>"DOM"</b> <sup>p845</sup>	Let <i>candidate</i> be the <a href="#">suitable sequentially focusable area</a> <sup>p846</sup> , that appears nearest after <i>starting point</i> in <i>starting point</i> 's <a href="#">Document</a> <sup>p130</sup> , in <a href="#">shadow-including tree order</a> , if any; or else null	Let <i>candidate</i> be the <a href="#">suitable sequentially focusable area</a> <sup>p846</sup> , that appears nearest before <i>starting point</i> in <i>starting point</i> 's <a href="#">Document</a> <sup>p130</sup> , in <a href="#">shadow-including tree order</a> , if any; or else null

	direction is "forward" <sup>p844</sup>	direction is "backward" <sup>p844</sup>
	<div>Note</div> <p>In this case, starting point does not necessarily belong to its Document<sup>p130</sup>'s sequential focus navigation order<sup>p844</sup>, so we'll select the suitable<sup>p846</sup> item from that list that comes after starting point in shadow-including tree order.</p>	
selection mechanism is "sequential" <sup>p845</sup>	Let candidate be the first suitable sequentially focusable area <sup>p846</sup> after starting point, in starting point's Document <sup>p130</sup> 's sequential focus navigation order <sup>p844</sup> , if any; or else null	Let candidate be the last suitable sequentially focusable area <sup>p846</sup> before starting point, in starting point's Document <sup>p130</sup> 's sequential focus navigation order <sup>p844</sup> , if any; or else null

A **suitable sequentially focusable area** is a [focusable area](#)<sup>p835</sup> whose [DOM anchor](#)<sup>p835</sup> is not [inert](#)<sup>p827</sup> and is [sequentially focusable](#)<sup>p837</sup>.

2. If candidate is a [navigable container](#)<sup>p991</sup> with a non-null [content navigable](#)<sup>p991</sup>, then:
  1. Let *recursive candidate* be the result of running the [sequential navigation search algorithm](#)<sup>p845</sup> with *candidate*'s [content navigable](#)<sup>p991</sup>, *direction*, and "[sequential](#)"<sup>p845</sup>.
  2. If *recursive candidate* is null, then return the result of running the [sequential navigation search algorithm](#)<sup>p845</sup> with *candidate*, *direction*, and *selection mechanism*.
  3. Otherwise, set *candidate* to *recursive candidate*.
3. Return *candidate*.

## 6.6.6 Focus management APIs <sup>p84</sup>

```
IDL dictionary FocusOptions {
    boolean preventScroll = false;
    boolean focusVisible;
};
```

### For web developers (non-normative)

#### **documentOrShadowRoot.activeElement**<sup>p847</sup>

Returns the deepest element in the document through which or to which key events are being routed. This is, roughly speaking, the focused element in the document.

For the purposes of this API, when a [child navigable](#)<sup>p992</sup> is focused, its [container](#)<sup>p991</sup> is [focused](#)<sup>p836</sup> within its [parent](#)<sup>p989</sup>'s [active document](#)<sup>p989</sup>. For example, if the user moves the focus to a text control in an [iframe](#)<sup>p390</sup>, the [iframe](#)<sup>p390</sup> is the element returned by the [activeElement](#)<sup>p847</sup> API in the [iframe](#)<sup>p390</sup>'s [node document](#).

Similarly, when the focused element is in a different [node tree](#) than *documentOrShadowRoot*, the element returned will be the [host](#) that's located in the same [node tree](#) as *documentOrShadowRoot* if *documentOrShadowRoot* is a [shadow-including inclusive ancestor](#) of the focused element, and null if not.

#### **document.hasFocus**<sup>p847</sup>()

Returns true if key events are being routed through or to the document; otherwise, returns false. Roughly speaking, this corresponds to the document, or a document nested inside this one, being focused.

#### **window.focus**<sup>p847</sup>()

Moves the focus to the window's [navigable](#)<sup>p923</sup>, if any.

#### **element.focus**<sup>p847</sup>([ { **preventScroll**<sup>p847</sup>: true } ])

Moves the focus to the element.

If the element is a [navigable container](#)<sup>p991</sup>, moves the focus to its [content navigable](#)<sup>p991</sup> instead.

By default, this method also scrolls the element into view. Providing the [preventScroll](#)<sup>p847</sup> option and setting it to true prevents this behavior.

## `element.blurp848()`

Moves the focus to the [viewport](#). Use of this method is discouraged; if you want to focus the [viewport](#), call the `focus()p847` method on the [Document<sup>p130</sup>](#)'s [document element](#).

Do not use this method to hide the focus ring if you find the focus ring unsightly. Instead, use the `:focus-visible` pseudo-class to override the `'outline'` property, and provide a different way to show what element is focused. Be aware that if an alternative focusing style isn't made available, the page will be significantly less usable for people who primarily navigate pages using a keyboard, or those with reduced vision who use focus outlines to help them navigate the page.

### Example

For example, to hide the outline from [textarea<sup>p579</sup>](#) elements and instead use a yellow background to indicate focus, you could use:

```
CSS textarea:focus-visible { outline: none; background: yellow; color: black; }
```

The `activeElement` attribute's getter must run these steps:

1. Let *candidate* be the [DOM anchor<sup>p835</sup>](#) of the [focused area<sup>p836</sup>](#) of this [DocumentOrShadowRoot<sup>p132</sup>](#)'s [node document](#).
2. Set *candidate* to the result of [retargeting candidate](#) against this [DocumentOrShadowRoot<sup>p132</sup>](#).
3. If *candidate*'s [root](#) is not this [DocumentOrShadowRoot<sup>p132</sup>](#), then return null.
4. If *candidate* is not a [Document<sup>p130</sup>](#) object, then return *candidate*.
5. If *candidate* has a [body element<sup>p136</sup>](#), then return that [body element<sup>p136</sup>](#).
6. If *candidate*'s [document element](#) is non-null, then return that [document element](#).
7. Return null.

The `hasFocus()` method on the [Document<sup>p130</sup>](#) object, when invoked, must return the result of running the [has focus steps<sup>p844</sup>](#) with the [Document<sup>p130</sup>](#) object as the argument.

The `focus()` method, when invoked, must run these steps:

1. Let *current* be this [Window<sup>p922</sup>](#) object's [navigable<sup>p923</sup>](#).
2. If *current* is null, then return.
3. Run the [focusing steps<sup>p842</sup>](#) with *current*.
4. If *current* is a [top-level traversable<sup>p990</sup>](#), user agents are encouraged to trigger some sort of notification to indicate to the user that the page is attempting to gain focus.

The `blur()` method steps are to do nothing.

### Note

Historically, the `focus()p847` and `blur()p847` methods actually affected the system-level focus of the system widget (e.g., tab or window) that contained the [navigable<sup>p989</sup>](#), but hostile sites widely abuse this behavior to the user's detriment.

The `focus(options)` method on elements, when invoked, must run the following steps:

1. If the element is marked as [locked for focus<sup>p847</sup>](#), then return.
2. Mark the element as **locked for focus**.
3. Run the [focusing steps<sup>p842</sup>](#) for the element.
4. If the value of the `focusVisible` dictionary member of *options* is true, or is not present but in an [implementation-defined](#) way the user agent determines it would be best to do so, then [indicate focus](#).
5. If the value of the `preventScroll` dictionary member of *options* is false, then [scroll the element into view](#) given "auto",

"center", and "center".

6. Unmark the element as [locked for focus](#)<sup>p847</sup>.

The [blur\(\)](#) method, when invoked, should run the [unfocusing steps](#)<sup>p842</sup> for the element on which the method was called. User agents may selectively or uniformly ignore calls to this method for usability reasons.

#### Example

For example, if the [blur\(\)](#)<sup>p848</sup> method is unwisely being used to remove the focus ring for aesthetics reasons, the page would become unusable by keyboard users. Ignoring calls to this method would thus allow keyboard users to interact with the page.

### 6.6.7 The [autofocus](#)<sup>p848</sup> attribute § p848

The [autofocus](#) content attribute allows the author to indicate that an element is to be focused as soon as the page is loaded, allowing the user to just start typing without having to manually focus the main element.

When the [autofocus](#)<sup>p848</sup> attribute is specified on an element inside [dialog](#)<sup>p646</sup> elements or [HTML elements](#)<sup>p45</sup> whose [popover](#)<sup>p886</sup> attribute is set, then it will be focused when the dialog or popover becomes shown.

The [autofocus](#)<sup>p848</sup> attribute is a [boolean attribute](#)<sup>p75</sup>.

To find the **nearest ancestor autofocus scoping root element** given an [Element](#) *element*:

1. If *element* is a [dialog](#)<sup>p646</sup> element, then return *element*.
2. If *element*'s [popover](#)<sup>p886</sup> attribute is not in the [no popover state](#)<sup>p887</sup>, then return *element*.
3. Let *ancestor* be *element*.
4. While *ancestor* has a [parent element](#):
  1. Set *ancestor* to *ancestor*'s [parent element](#).
  2. If *ancestor* is a [dialog](#)<sup>p646</sup> element, then return *ancestor*.
  3. If *ancestor*'s [popover](#)<sup>p886</sup> attribute is not in the [no popover state](#)<sup>p887</sup>, then return *ancestor*.
5. Return *ancestor*.

There must not be two elements with the same [nearest ancestor autofocus scoping root element](#)<sup>p848</sup> that both have the [autofocus](#)<sup>p848</sup> attribute specified.

Each [Document](#)<sup>p130</sup> has an **autofocus candidates** [list](#), initially empty.

Each [Document](#)<sup>p130</sup> has an **autofocus processed flag** boolean, initially false.

When an element with the [autofocus](#)<sup>p848</sup> attribute specified is [inserted into a document](#)<sup>p46</sup>, run the following steps:

1. If the user has indicated (for example, by starting to type in a form control) that they do not wish focus to be changed, then optionally return.
2. Let *target* be the element's [node document](#).
3. If *target* is not [fully active](#)<sup>p1003</sup>, then return.
4. If *target*'s [active sandboxing flag set](#)<sup>p917</sup> has the [sandboxed automatic features browsing context flag](#)<sup>p915</sup>, then return.
5. [For each](#) *ancestorNavigable* of *target*'s [ancestor navigables](#)<sup>p994</sup>: if *ancestorNavigable*'s [active document](#)<sup>p989</sup>'s [origin](#) is not [same origin](#)<sup>p899</sup> with *target*'s [origin](#), then return.
6. Let *topDocument* be *target*'s [node navigable](#)<sup>p989</sup>'s [top-level traversable](#)<sup>p990</sup>'s [active document](#)<sup>p989</sup>.
7. If *topDocument*'s [autofocus processed flag](#)<sup>p848</sup> is false, then [remove](#) the element from *topDocument*'s [autofocus candidates](#)<sup>p848</sup>, and [append](#) the element to *topDocument*'s [autofocus candidates](#)<sup>p848</sup>.

**Note**

We do not check if an element is a [focusable area](#)<sup>p835</sup> before storing it in the [autofocus candidates](#)<sup>p848</sup> list, because even if it is not a focusable area when it is inserted, it could become one by the time [flush autofocus candidates](#)<sup>p849</sup> sees it.

To **flush autofocus candidates** for a document *topDocument*, run these steps:

1. If *topDocument*'s [autofocus processed flag](#)<sup>p848</sup> is true, then return.
2. Let *candidates* be *topDocument*'s [autofocus candidates](#)<sup>p848</sup>.
3. If *candidates* is [empty](#), then return.
4. If *topDocument*'s [focused area](#)<sup>p836</sup> is not *topDocument* itself, or *topDocument* has non-null [target element](#)<sup>p1054</sup>, then:
  1. [Empty](#) *candidates*.
  2. Set *topDocument*'s [autofocus processed flag](#)<sup>p848</sup> to true.
  3. Return.
5. While *candidates* is not [empty](#):
  1. Let *element* be *candidates*[0].
  2. Let *doc* be *element*'s [node document](#).
  3. If *doc* is not [fully active](#)<sup>p1003</sup>, then [remove](#) *element* from *candidates*, and [continue](#).
  4. If *doc*'s [node navigable](#)<sup>p989</sup>'s [top-level traversable](#)<sup>p990</sup> is not the same as *topDocument*'s [node navigable](#)<sup>p989</sup>, then [remove](#) *element* from *candidates*, and [continue](#).
  5. If *doc*'s [script-blocking style sheet set](#)<sup>p204</sup> is not [empty](#), then return.

**Note**

In this case, *element* is the currently-best candidate, but *doc* is not ready for autofocusing. We'll try again next time [flush autofocus candidates](#)<sup>p849</sup> is called.

6. [Remove](#) *element* from *candidates*.
7. Let *inclusiveAncestorDocuments* be a [list](#) consisting of the [active document](#)<sup>p989</sup> of *doc*'s [inclusive ancestor navigables](#)<sup>p994</sup>.
8. If any [Document](#)<sup>p130</sup> in *inclusiveAncestorDocuments* has non-null [target element](#)<sup>p1054</sup>, then [continue](#).
9. Let *target* be *element*.
10. If *target* is not a [focusable area](#)<sup>p835</sup>, then set *target* to the result of [getting the focusable area](#)<sup>p840</sup> for *target*.

**Note**

[Autofocus candidates](#)<sup>p848</sup> can contain elements which are not [focusable areas](#)<sup>p835</sup>. In addition to the special cases handled in the [get the focusable area](#)<sup>p840</sup> algorithm, this can happen because a non-[focusable area](#)<sup>p835</sup> element with an [autofocus](#)<sup>p848</sup> attribute was [inserted into a document](#)<sup>p46</sup> and it never became focusable, or because the element was focusable but its status changed while it was stored in [autofocus candidates](#)<sup>p848</sup>.

11. If *target* is not null, then:
  1. [Empty](#) *candidates*.
  2. Set *topDocument*'s [autofocus processed flag](#)<sup>p848</sup> to true.
  3. Run the [focusing steps](#)<sup>p842</sup> for *target*.

**Note**

This handles the automatic focusing during document load. The [show\(\)](#)<sup>p649</sup> and [showModal\(\)](#)<sup>p649</sup> methods of [dialog](#)<sup>p646</sup> elements also processes the [autofocus](#)<sup>p848</sup> attribute.

## Note

Focusing the element does not imply that the user agent has to focus the browser window if it has lost focus.

The **autofocus** IDL attribute must [reflect](#)<sup>p104</sup> the content attribute of the same name.

## Example

In the following snippet, the text control would be focused when the document was loaded.

```
<input maxlength="256" name="q" value="" autofocus>
<input type="submit" value="Search">
```

## Example

The **autofocus**<sup>p848</sup> attribute applies to all elements, not just to form controls. This allows examples such as the following:

```
<div contenteditable autofocus>Edit <strong>me!</strong></div>
```

## 6.7 Assigning keyboard shortcuts §<sup>p85</sup><sub>0</sub>

### 6.7.1 Introduction §<sup>p85</sup><sub>0</sub>

*This section is non-normative.*

Each element that can be activated or focused can be assigned a single key combination to activate it, using the **accesskey**<sup>p851</sup> attribute.

The exact shortcut is determined by the user agent, based on information about the user's keyboard, what keyboard shortcuts already exist on the platform, and what other shortcuts have been specified on the page, using the information provided in the **accesskey**<sup>p851</sup> attribute as a guide.

In order to ensure that a relevant keyboard shortcut is available on a wide variety of input devices, the author can provide a number of alternatives in the **accesskey**<sup>p851</sup> attribute.

Each alternative consists of a single character, such as a letter or digit.

User agents can provide users with a list of the keyboard shortcuts, but authors are encouraged to do so also. The **accessKeyLabel**<sup>p852</sup> IDL attribute returns a string representing the actual key combination assigned by the user agent.

## Example

In this example, an author has provided a button that can be invoked using a shortcut key. To support full keyboards, the author has provided "C" as a possible key. To support devices equipped only with numeric keypads, the author has provided "1" as another possible key.

```
<input type=button value=Collect onclick="collect()"
      accesskey="C 1" id=c>
```

## Example

To tell the user what the shortcut key is, the author has this script here opted to explicitly add the key combination to the button's label:

```
function addShortcutKeyLabel(button) {
  if (button.accessKeyLabel != '')
    button.value += ' (' + button.accessKeyLabel + ')';
}
addShortcutKeyLabel(document.getElementById('c'));
```

Browsers on different platforms will show different labels, even for the same key combination, based on the convention prevalent on that platform. For example, if the key combination is the Control key, the Shift key, and the letter C, a Windows browser might display "Ctrl+Shift+C", whereas a Mac browser might display "⌘⇧C", while an Emacs browser might just display "C-C". Similarly, if the key combination is the Alt key and the Escape key, Windows might use "Alt+Esc", Mac might use "⌘↵", and an Emacs browser might use "M-ESC" or "ESC ESC".

In general, therefore, it is unwise to attempt to parse the value returned from the [accessKeyLabel](#)<sup>p852</sup> IDL attribute.

## 6.7.2 The **accesskey** attribute <sup>§ p85</sup><sub>1</sub>

All [HTML elements](#)<sup>p45</sup> may have the [accesskey](#)<sup>p851</sup> content attribute set. The [accesskey](#)<sup>p851</sup> attribute's value is used by the user agent as a guide for creating a keyboard shortcut that activates or focuses the element.

If specified, the value must be an [ordered set of unique space-separated tokens](#)<sup>p95</sup> none of which are [identical to](#) another token and each of which must be exactly one code point in length.

### Example

In the following example, a variety of links are given with access keys so that keyboard users familiar with the site can more quickly navigate to the relevant pages:

```
<nav>
  <p>
    <a title="Consortium Activities" accesskey="A" href="/Consortium/activities">Activities</a> |
    <a title="Technical Reports and Recommendations" accesskey="T" href="/TR/">Technical Reports</a>
  |
    <a title="Alphabetical Site Index" accesskey="S" href="/Consortium/siteindex">Site Index</a> |
    <a title="About This Site" accesskey="B" href="/Consortium/">About Consortium</a> |
    <a title="Contact Consortium" accesskey="C" href="/Consortium/contact">Contact</a>
  </p>
</nav>
```

### Example

In the following example, the search field is given two possible access keys, "s" and "0" (in that order). A user agent on a device with a full keyboard might pick Ctrl + Alt + S as the shortcut key, while a user agent on a small device with just a numeric keypad might pick just the plain unadorned key 0:

```
<form action="/search">
  <label>Search: <input type="search" name="q" accesskey="s 0"></label>
  <input type="submit">
</form>
```

### Example

In the following example, a button has possible access keys described. A script then tries to update the button's label to advertise the key combination the user agent selected.

```
<input type=submit accesskey="N @ 1" value="Compose">
...
<script>
  function labelButton(button) {
    if (button.accessKeyLabel)
      button.value += ' (' + button.accessKeyLabel + ')';
  }
  var inputs = document.getElementsByTagName('input');
  for (var i = 0; i < inputs.length; i += 1) {
```

```

    if (inputs[i].type == "submit")
        labelButton(inputs[i]);
    }
</script>

```

On one user agent, the button's label might become "Compose (%N)". On another, it might become "Compose (Alt+⌘+1)". If the user agent doesn't assign a key, it will be just "Compose". The exact string depends on what the [assigned access key<sup>p852</sup>](#) is, and on how the user agent represents that key combination.

### 6.7.3 Processing model <sup>p85</sup><sub>2</sub>

An element's **assigned access key** is a key combination derived from the element's [accesskey<sup>p851</sup>](#) content attribute. Initially, an element must not have an [assigned access key<sup>p852</sup>](#).

Whenever an element's [accesskey<sup>p851</sup>](#) attribute is set, changed, or removed, the user agent must update the element's [assigned access key<sup>p852</sup>](#) by running the following steps:

1. If the element has no [accesskey<sup>p851</sup>](#) attribute, then skip to the *fallback* step below.
2. Otherwise, [split the attribute's value on ASCII whitespace](#), and let *keys* be the resulting tokens.
3. For each value in *keys* in turn, in the order the tokens appeared in the attribute's value, run the following substeps:
  1. If the value is not a string exactly one code point in length, then skip the remainder of these steps for this value.
  2. If the value does not correspond to a key on the system's keyboard, then skip the remainder of these steps for this value.
  3. If the user agent can find a mix of zero or more modifier keys that, combined with the key that corresponds to the value given in the attribute, can be used as the access key, then the user agent may assign that combination of keys as the element's [assigned access key<sup>p852</sup>](#) and return.
4. *Fallback*: Optionally, the user agent may assign a key combination of its choosing as the element's [assigned access key<sup>p852</sup>](#) and then return.
5. If this step is reached, the element has no [assigned access key<sup>p852</sup>](#).

Once a user agent has selected and assigned an access key for an element, the user agent should not change the element's [assigned access key<sup>p852</sup>](#) unless the [accesskey<sup>p851</sup>](#) content attribute is changed or the element is moved to another [Document<sup>p130</sup>](#).

When the user presses the key combination corresponding to the [assigned access key<sup>p852</sup>](#) for an element, if the element [defines a command<sup>p643</sup>](#), the command's [Hidden State<sup>p644</sup>](#) facet is false (visible), the command's [Disabled State<sup>p644</sup>](#) facet is also false (enabled), the element is [in a document](#) that has a non-null [browsing context<sup>p999</sup>](#), and neither the element nor any of its ancestors has a [hidden<sup>p824</sup>](#) attribute specified, then the user agent must trigger the [Action<sup>p644</sup>](#) of the command.

#### Note

*User agents [might expose<sup>p644</sup>](#) elements that have an [accesskey<sup>p851</sup>](#) attribute in other ways as well, e.g. in a menu displayed in response to a specific key combination.*

The **accessKey** IDL attribute must [reflect<sup>p104</sup>](#) the [accesskey<sup>p851</sup>](#) content attribute.

The **accessKeyLabel** IDL attribute must return a string that represents the element's [assigned access key<sup>p852</sup>](#), if any. If the element does not have one, then the IDL attribute must return the empty string.

6.8.1 Making document regions editable: The `contenteditable` content attribute § p853

```
IDL interface mixin ElementContentEditable {
  [CEReactions] attribute DOMString contentEditable;
  [CEReactions] attribute DOMString enterKeyHint;
  readonly attribute boolean isContentEditable;
  [CEReactions] attribute DOMString inputMode;
};
```

The `contenteditable` content attribute is an [enumerated attribute](#) with the following keywords and states:

Keyword	State	Brief description
<code>true</code> (the empty string)	<code>true</code>	The element is editable.
<code>false</code>	<code>false</code>	The element is not editable.
<code>plaintext-only</code>	<code>plaintext-only</code>	Only the element's raw text content is editable; rich formatting is disabled.

The attribute's [missing value default](#) and [invalid value default](#) are both the **inherit** state. The inherit state indicates that the element is editable (or not) based on the parent element's state.

Example

For example, consider a page that has a `form` and a `textarea` to publish a new article, where the user is expected to write the article using HTML:

```
<form method=POST>
  <fieldset>
    <legend>New article</legend>
    <textarea name=article>&lt;p>Hello world.&lt;/p></textarea>
  </fieldset>
  <p><button>Publish</button></p>
</form>
```

When scripting is enabled, the `textarea` element could be replaced with a rich text control instead, using the `contenteditable` attribute:

```
<form method=POST>
  <fieldset>
    <legend>New article</legend>
    <textarea id=textarea name=article>&lt;p>Hello world.&lt;/p></textarea>
    <div id=div style="white-space: pre-wrap" hidden><p>Hello world.</p></div>
  </fieldset>
  <script>
    let textarea = document.getElementById("textarea");
    let div = document.getElementById("div");
    textarea.hidden = true;
    div.hidden = false;
    div.contentEditable = "true";
    div.oninput = (e) => {
      textarea.value = div.innerHTML;
    };
  </script>
  <p><button>Publish</button></p>
</form>
```

Features to enable, e.g., inserting links, can be implemented using the `document.execCommand()` API, or using [Selection](#) APIs and other DOM APIs. [\[EXECCOMMAND\]](#) [\[SELECTION\]](#) [\[DOM\]](#)

Example

The [contenteditable](#)<sup>p853</sup> attribute can also be used to great effect:

```
<!doctype html>
<html lang=en>
<title>Live CSS editing!</title>
<style style=white-space:pre contenteditable>
html { margin:.2em; font-size:2em; color:lime; background:purple }
head, title, style { display:block }
body { display:none }
</style>
```

For web developers (non-normative)

**`element.contentEditable`**<sup>p854</sup> [ = *value* ]

Returns "true", "plaintext-only", "false", or "[inherit](#)<sup>p853</sup>", based on the state of the [contenteditable](#)<sup>p853</sup> attribute.

Can be set, to change that state.

Throws a "[SyntaxError](#)" [DOMException](#) if the new value isn't one of those strings.

**`element.isContentEditable`**<sup>p854</sup>

Returns true if the element is editable; otherwise, returns false.

The **contentEditable** IDL attribute, on getting, must return the string "true" if the content attribute is set to the [true](#)<sup>p853</sup> state, "plaintext-only" if the content attribute is set to the [plaintext-only](#)<sup>p853</sup> state, "false" if the content attribute is set to the [false](#)<sup>p853</sup> state, and "[inherit](#)<sup>p853</sup>" otherwise. On setting, if the new value is an [ASCII case-insensitive](#) match for the string "inherit" then the content attribute must be removed, if the new value is an [ASCII case-insensitive](#) match for the string "true" then the content attribute must be set to the string "true", if the new value is an [ASCII case-insensitive](#) match for the string "plaintext-only" then the content attribute must be set to the string "plaintext-only", if the new value is an [ASCII case-insensitive](#) match for the string "false" then the content attribute must be set to the string "false", and otherwise the attribute setter must throw a "[SyntaxError](#)" [DOMException](#).

The **isContentEditable** IDL attribute, on getting, must return true if the element is either an [editing host](#)<sup>p855</sup> or [editable](#), and false otherwise.

## 6.8.2 Making entire documents editable: the [designMode](#)<sup>p854</sup> getter and setter § <sup>p85</sup><sub>4</sub>

For web developers (non-normative)

**`document.designMode`**<sup>p854</sup> [ = *value* ]

Returns "on" if the document is editable, and "off" if it isn't.

Can be set, to change the document's current state. This focuses the document and resets the selection in that document.

[Document](#)<sup>p130</sup> objects have an associated **design mode enabled**, which is a boolean. It is initially false.

The **designMode** getter steps are to return "on" if [this](#)'s [design mode enabled](#)<sup>p854</sup> is true; otherwise "off".

The [designMode](#)<sup>p854</sup> setter steps are:

1. Let *value* be the given value, [converted to ASCII lowercase](#).
2. If *value* is "on" and [this](#)'s [design mode enabled](#)<sup>p854</sup> is false, then:
  1. Set [this](#)'s [design mode enabled](#)<sup>p854</sup> to true.
  2. Reset [this](#)'s [active range](#)'s start and end boundary points to be at the start of [this](#).
  3. Run the [focusing steps](#)<sup>p842</sup> for [this](#)'s [document element](#), if non-null.
3. If *value* is "off", then set [this](#)'s [design mode enabled](#)<sup>p854</sup> to false.

6.8.3 Best practices for in-page editors § p855

Authors are encouraged to set the `'white-space'` property on [editing hosts](#)<sup>p855</sup> and on markup that was originally created through these editing mechanisms to the value `'pre-wrap'`. Default HTML whitespace handling is not well suited to WYSIWYG editing, and line wrapping will not work correctly in some corner cases if `'white-space'` is left at its default value.

Example

As an example of problems that occur if the default `'normal'` value is used instead, consider the case of the user typing "yellow<sub>␣</sub>ball", with two spaces (here represented by "<sub>␣</sub>") between the words. With the editing rules in place for the default value of `'white-space'` (`'normal'`), the resulting markup will either consist of "yellow&nbsp; ball" or "yellow &nbsp;ball"; i.e., there will be a non-breaking space between the two words in addition to the regular space. This is necessary because the `'normal'` value for `'white-space'` requires adjacent regular spaces to be collapsed together.

In the former case, "yellow<sub>␣</sub>" might wrap to the next line ("<sub>␣</sub>" being used here to represent a non-breaking space) even though "yellow" alone might fit at the end of the line; in the latter case, "<sub>␣</sub>ball", if wrapped to the start of the line, would have visible indentation from the non-breaking space.

When `'white-space'` is set to `'pre-wrap'`, however, the editing rules will instead simply put two regular spaces between the words, and should the two words be split at the end of a line, the spaces would be neatly removed from the rendering.

6.8.4 Editing APIs § p855

An **editing host** is either an [HTML element](#)<sup>p45</sup> with its [contenteditable](#)<sup>p853</sup> attribute in the *true* state or *plaintext-only* state, or a [child HTML element](#)<sup>p45</sup> of a [Document](#)<sup>p130</sup> whose [design mode enabled](#)<sup>p854</sup> is true.

The definition of the terms **active range**, **editing host of**, and **editable**, the user interface requirements of elements that are [editing hosts](#)<sup>p855</sup> or **editable**, the [execCommand\(\)](#), [queryCommandEnabled\(\)](#), [queryCommandIndeterm\(\)](#), [queryCommandState\(\)](#), [queryCommandSupported\(\)](#), and [queryCommandValue\(\)](#) methods, text selections, and the **delete the selection** algorithm are defined in [execCommand](#). [\[EXECCOMMAND\]](#)<sup>p1478</sup>

6.8.5 Spelling and grammar checking § p855

User agents can support the checking of spelling and grammar of editable text, either in form controls (such as the value of [textarea](#)<sup>p579</sup> elements), or in elements in an [editing host](#)<sup>p855</sup> (e.g. using [contenteditable](#)<sup>p853</sup>).

For each element, user agents must establish a **default behavior**, either through defaults or through preferences expressed by the user. There are three possible default behaviors for each element:

true-by-default

The element will be checked for spelling and grammar if its contents are editable and spellchecking is not explicitly disabled through the [spellcheck](#)<sup>p855</sup> attribute.

false-by-default

The element will never be checked for spelling and grammar unless spellchecking is explicitly enabled through the [spellcheck](#)<sup>p855</sup> attribute.

inherit-by-default

The element's default behavior is the same as its parent element's. Elements that have no parent element cannot have this as their default behavior.

The [spellcheck](#) attribute is an [enumerated attribute](#)<sup>p76</sup> with the following keywords and states:

Keyword	State	Brief description
<a href="#">true</a> (the empty string)	<b>true</b>	Spelling and grammar will be checked.
<a href="#">false</a>	<b>false</b>	Spelling and grammar will not be checked.

The attribute's [missing value default](#)<sup>p76</sup> and [invalid value default](#)<sup>p76</sup> are both the **default** state. The default state indicates that the

element is to act according to a default behavior, possibly based on the parent element's own [spellcheck](#)<sup>p855</sup> state, as defined below.

For web developers (non-normative)

**`element.spellcheck`**<sup>p856</sup> [ = *value* ]

Returns true if the element is to have its spelling and grammar checked; otherwise, returns false.

Can be set, to override the default and set the [spellcheck](#)<sup>p855</sup> content attribute.

The [spellcheck](#) IDL attribute, on getting, must return true if the element's [spellcheck](#)<sup>p855</sup> content attribute is in the [true](#)<sup>p855</sup> state, or if the element's [spellcheck](#)<sup>p855</sup> content attribute is in the [default](#)<sup>p855</sup> state and the element's [default behavior](#)<sup>p855</sup> is [true-by-default](#)<sup>p855</sup>, or if the element's [spellcheck](#)<sup>p855</sup> content attribute is in the [default](#)<sup>p855</sup> state and the element's [default behavior](#)<sup>p855</sup> is [inherit-by-default](#)<sup>p855</sup> and the element's parent element's [spellcheck](#)<sup>p856</sup> IDL attribute would return true; otherwise, if none of those conditions applies, then the attribute must instead return false.

Note

*The [spellcheck](#)<sup>p856</sup> IDL attribute is not affected by user preferences that override the [spellcheck](#)<sup>p855</sup> content attribute, and therefore might not reflect the actual spellchecking state.*

On setting, if the new value is true, then the element's [spellcheck](#)<sup>p855</sup> content attribute must be set to "true", otherwise it must be set to "false".

User agents should only consider the following pieces of text as checkable for the purposes of this feature:

- The [value](#)<sup>p597</sup> of [input](#)<sup>p520</sup> elements whose [type](#)<sup>p523</sup> attributes are in the [Text](#)<sup>p527</sup>, [Search](#)<sup>p527</sup>, [URL](#)<sup>p529</sup>, or [Email](#)<sup>p530</sup> states and that are [mutable](#)<sup>p597</sup> (i.e. that do not have the [readonly](#)<sup>p551</sup> attribute specified and that are not [disabled](#)<sup>p601</sup>).
- The [value](#)<sup>p597</sup> of [textarea](#)<sup>p579</sup> elements that do not have a [readonly](#)<sup>p581</sup> attribute and that are not [disabled](#)<sup>p601</sup>.
- Text in [Text](#) nodes that are children of [editing hosts](#)<sup>p855</sup> or [editable](#) elements.
- Text in attributes of [editable](#) elements.

For text that is part of a [Text](#) node, the element with which the text is associated is the element that is the immediate parent of the first character of the word, sentence, or other piece of text. For text in attributes, it is the attribute's element. For the values of [input](#)<sup>p520</sup> and [textarea](#)<sup>p579</sup> elements, it is the element itself.

To determine if a word, sentence, or other piece of text in an applicable element (as defined above) is to have spelling- and grammar-checking enabled, the UA must use the following algorithm:

1. If the user has disabled the checking for this text, then the checking is disabled.
2. Otherwise, if the user has forced the checking for this text to always be enabled, then the checking is enabled.
3. Otherwise, if the element with which the text is associated has a [spellcheck](#)<sup>p855</sup> content attribute, then: if that attribute is in the [true](#)<sup>p855</sup> state, then checking is enabled; otherwise, if that attribute is in the [false](#)<sup>p855</sup> state, then checking is disabled.
4. Otherwise, if there is an ancestor element with a [spellcheck](#)<sup>p855</sup> content attribute that is not in the [default](#)<sup>p855</sup> state, then: if the nearest such ancestor's [spellcheck](#)<sup>p855</sup> content attribute is in the [true](#)<sup>p855</sup> state, then checking is enabled; otherwise, checking is disabled.
5. Otherwise, if the element's [default behavior](#)<sup>p855</sup> is [true-by-default](#)<sup>p855</sup>, then checking is enabled.
6. Otherwise, if the element's [default behavior](#)<sup>p855</sup> is [false-by-default](#)<sup>p855</sup>, then checking is disabled.
7. Otherwise, if the element's parent element has *its* checking enabled, then checking is enabled.
8. Otherwise, checking is disabled.

If the checking is enabled for a word/sentence/text, the user agent should indicate spelling and grammar errors in that text. User agents should take into account the other semantics given in the document when suggesting spelling and grammar corrections. User agents may use the language of the element to determine what spelling and grammar rules to use, or may use the user's preferred language settings. UAs should use [input](#)<sup>p520</sup> element attributes such as [pattern](#)<sup>p554</sup> to ensure that the resulting value is valid, where possible.

If checking is disabled, the user agent should not indicate spelling or grammar errors for that text.

Example

The element with ID "a" in the following example would be the one used to determine if the word "Hello" is checked for spelling errors. In this example, it would not be.

```
<div contenteditable="true">
  <span spellcheck="false" id="a">Hell</span><em>o!</em>
</div>
```

The element with ID "b" in the following example would have checking enabled (the leading space character in the attribute's value on the `input` <sup>p520</sup> element causes the attribute to be ignored, so the ancestor's value is used instead, regardless of the default).

```
<p spellcheck="true">
  <label>Name: <input spellcheck=" false" id="b"></label>
</p>
```

Note

*This specification does not define the user interface for spelling and grammar checkers. A user agent could offer on-demand checking, could perform continuous checking while the checking is enabled, or could use other interfaces.*

6.8.6 Writing suggestions <sup>§ p85</sup><sub>7</sub>

User agents offer writing suggestions as users type into editable regions, either in form controls (e.g., the `textarea` <sup>p579</sup> element) or in elements in an `editing host` <sup>p855</sup>.

The `writingsuggestions` content attribute is an `enumerated attribute` <sup>p76</sup> with the following keywords and states:

Keyword	State	Brief description
<code>true</code>	<code>true</code>	Writing suggestions should be offered on this element.
(the empty string)		
<code>false</code>	<code>false</code>	Writing suggestions should not be offered on this element.

The attribute's `missing value default` <sup>p76</sup> is the **default** state. The default state indicates that the element is to act according to a default behavior, possibly based on the parent element's own `writingsuggestions` <sup>p857</sup> state, as defined below.

The attribute's `invalid value default` <sup>p76</sup> is the `true` <sup>p857</sup> state.

For web developers (non-normative)

```
element.writingSuggestions p857 [ = value ]
  Returns "true" if the user agent is to offer writing suggestions under the scope of the element; otherwise, returns "false".
  Can be set, to override the default and set the writingsuggestions p857 content attribute.
```

The **computed writing suggestions value** of a given *element* is determined by running the following steps:

1. If *element*'s `writingsuggestions` <sup>p857</sup> content attribute is in the `false` <sup>p857</sup> state, return "false".
2. If *element*'s `writingsuggestions` <sup>p857</sup> content attribute is in the `default` <sup>p857</sup> state, *element* has a parent element, and the `computed writing suggestions value` <sup>p857</sup> of *element*'s parent element is "false", then return "false".
3. Return "true".

The `writingSuggestions` getter steps are:

1. Return *this*'s `computed writing suggestions value` <sup>p857</sup>.

## Note

The `writingSuggestions`<sup>p857</sup> IDL attribute is not affected by user preferences that override the `writingsuggestions`<sup>p857</sup> content attribute, and therefore might not reflect the actual writing suggestions state.

The `writingSuggestions`<sup>p857</sup> setter steps are:

1. Set `this`'s `writingsuggestions`<sup>p857</sup> content attribute to the given value.

User agents should only offer suggestions within an element's scope if the result of running the following algorithm given *element* returns true:

1. If the user has disabled writing suggestions, then return false.
2. If none of the following conditions are true:
  - *element* is an `input`<sup>p520</sup> element whose `type`<sup>p523</sup> attribute is in either the `Text`<sup>p527</sup>, `Search`<sup>p527</sup>, `Telephone`<sup>p528</sup>, `URL`<sup>p529</sup>, or `Email`<sup>p530</sup> state and is `mutable`<sup>p597</sup>;
  - *element* is a `textarea`<sup>p579</sup> element that is `mutable`<sup>p597</sup>; or
  - *element* is an `editing host`<sup>p855</sup> or is `editable`,then return false.
3. If *element* has an `inclusive ancestor` with a `writingsuggestions`<sup>p857</sup> content attribute that's not in the `default`<sup>p857</sup> and the nearest such ancestor's `writingsuggestions`<sup>p857</sup> content attribute is in the `false`<sup>p857</sup> state, then return false.
4. Otherwise, return true.

## Note

This specification does not define the user interface for writing suggestions. A user agent could offer on-demand suggestions, continuous suggestions as the user types, inline suggestions, autofill-like suggestions in a popup, or could use other interfaces.

## 6.8.7 Autocapitalization §<sup>p85</sup><sub>8</sub>

Some methods of entering text, for example virtual keyboards on mobile devices, and also voice input, often assist users by automatically capitalizing the first letter of sentences (when composing text in a language with this convention). A virtual keyboard that implements autocapitalization might automatically switch to showing uppercase letters (but allow the user to toggle it back to lowercase) when a letter that should be autocapitalized is about to be typed. Other types of input, for example voice input, may perform autocapitalization in a way that does not give users an option to intervene first. The `autocapitalize`<sup>p859</sup> attribute allows authors to control such behavior.

The `autocapitalize`<sup>p859</sup> attribute, as typically implemented, does not affect behavior when typing on a physical keyboard. (For this reason, as well as the ability for users to override the autocapitalization behavior in some cases or edit the text after initial input, the attribute must not be relied on for any sort of input validation.)

The `autocapitalize`<sup>p859</sup> attribute can be used on an `editing host`<sup>p855</sup> to control autocapitalization behavior for the hosted editable region, on an `input`<sup>p520</sup> or `textarea`<sup>p579</sup> element to control the behavior for inputting text into that element, or on a `form`<sup>p514</sup> element to control the default behavior for all `autocapitalize-and-autocorrect inheriting elements`<sup>p514</sup> associated with the `form`<sup>p514</sup> element.

The `autocapitalize`<sup>p859</sup> attribute never causes autocapitalization to be enabled for `input`<sup>p520</sup> elements whose `type`<sup>p523</sup> attribute is in one of the `URL`<sup>p529</sup>, `Email`<sup>p530</sup>, or `Password`<sup>p531</sup> states. (This behavior is included in the `used autocapitalization hint`<sup>p859</sup> algorithm below.)

The autocapitalization processing model is based on selecting among five **autocapitalization hints**, defined as follows:

### default

The user agent and input method should make their own determination of whether or not to enable autocapitalization.

### none

No autocapitalization should be applied (all letters should default to lowercase).

**sentences**

The first letter of each sentence should default to a capital letter; all other letters should default to lowercase.

**words**

The first letter of each word should default to a capital letter; all other letters should default to lowercase.

**characters**

All letters should default to uppercase.

The **autocapitalize** attribute is an [enumerated attribute](#)<sup>p76</sup> whose states are the possible [autocapitalization hints](#)<sup>p858</sup>. The [autocapitalization hint](#)<sup>p858</sup> specified by the attribute's state combines with other considerations to form the [used autocapitalization hint](#)<sup>p859</sup>, which informs the behavior of the user agent. The keywords for this attribute and their state mappings are as follows:

Keyword	State
off	<a href="#">none</a> <sup>p858</sup>
none	
on	<a href="#">sentences</a> <sup>p859</sup>
sentences	
words	<a href="#">words</a> <sup>p859</sup>
characters	<a href="#">characters</a> <sup>p859</sup>

The attribute's [missing value default](#)<sup>p76</sup> is the [default](#)<sup>p858</sup> state, and its [invalid value default](#)<sup>p76</sup> is the [sentences](#)<sup>p859</sup> state.

For web developers (non-normative)

**element.autocapitalize**<sup>p859</sup> [ = value ]

Returns the current autocapitalization state for the element, or an empty string if it hasn't been set. Note that for [input](#)<sup>p520</sup> and [textarea](#)<sup>p579</sup> elements that inherit their state from a [form](#)<sup>p514</sup> element, this will return the autocapitalization state of the [form](#)<sup>p514</sup> element, but for an element in an editable region, this will not return the autocapitalization state of the editing host (unless this element is, in fact, the [editing host](#)<sup>p855</sup>).

Can be set, to set the [autocapitalize](#)<sup>p859</sup> content attribute (and thereby change the autocapitalization behavior for the element).

To compute the **own autocapitalization hint** of an element *element*, run the following steps:

1. If the [autocapitalize](#)<sup>p859</sup> content attribute is present on *element*, and its value is not the empty string, return the state of the attribute.
2. If *element* is an [autocapitalize-and-autocorrect inheriting element](#)<sup>p514</sup> and has a non-null [form owner](#)<sup>p598</sup>, return the [own autocapitalization hint](#)<sup>p859</sup> of *element*'s [form owner](#)<sup>p598</sup>.
3. Return [default](#)<sup>p858</sup>.

The **autocapitalize** getter steps are to:

1. Let *state* be the [own autocapitalization hint](#)<sup>p859</sup> of *this*.
2. If *state* is [default](#)<sup>p858</sup>, then return the empty string.
3. If *state* is [none](#)<sup>p858</sup>, then return "[none](#)<sup>p859</sup>".
4. If *state* is [sentences](#)<sup>p859</sup>, then return "[sentences](#)<sup>p859</sup>".
5. Return the keyword value corresponding to *state*.

The [autocapitalize](#)<sup>p859</sup> setter steps are to set the [autocapitalize](#)<sup>p859</sup> content attribute to the given value.

User agents that support customizable autocapitalization behavior for a text input method and wish to allow web developers to control this functionality should, during text input into an element, compute the **used autocapitalization hint** for the element. This will be an [autocapitalization hint](#)<sup>p858</sup> that describes the recommended autocapitalization behavior for text input into the element.

User agents or input methods may choose to ignore or override the [used autocapitalization hint](#)<sup>p859</sup> in certain circumstances.

The [used autocapitalization hint](#)<sup>p859</sup> for an element *element* is computed using the following algorithm:

1. If *element* is an [input](#)<sup>p520</sup> element whose [type](#)<sup>p523</sup> attribute is in one of the [URL](#)<sup>p529</sup>, [Email](#)<sup>p530</sup>, or [Password](#)<sup>p531</sup> states, then return [default](#)<sup>p858</sup>.
2. If *element* is an [input](#)<sup>p520</sup> element or a [textarea](#)<sup>p579</sup> element, then return *element*'s [own autocapitalization hint](#)<sup>p859</sup>.
3. If *element* is an [editing host](#)<sup>p855</sup> or an [editable](#) element, then return the [own autocapitalization hint](#)<sup>p859</sup> of the [editing host of element](#).
4. [Assert](#): this step is never reached, since text input only occurs in elements that meet one of the above criteria.

**6.8.8 Autocorrection** §<sup>p86</sup><sub>0</sub>

Some methods of entering text assist users by automatically correcting misspelled words while typing, a process also known as autocorrection. User agents can support autocorrection of editable text, either in form controls (such as the value of [textarea](#)<sup>p579</sup> elements), or in elements in an [editing host](#)<sup>p855</sup> (e.g., using [contenteditable](#)<sup>p853</sup>). Autocorrection may be accompanied by user interfaces indicating that text is about to be autocorrected or has been autocorrected, and is commonly performed when inserting punctuation characters, spaces, or new paragraphs after misspelled words. The [autocorrect](#)<sup>p860</sup> attribute allows authors to control such behavior.

The [autocorrect](#)<sup>p860</sup> attribute can be used on an editing host to control autocorrection behavior for the hosted editable region, on an [input](#)<sup>p520</sup> or [textarea](#)<sup>p579</sup> element to control the behavior when inserting text into that element, or on a [form](#)<sup>p514</sup> element to control the default behavior for all [autocapitalize-and-autocorrect inheriting elements](#)<sup>p514</sup> associated with the [form](#)<sup>p514</sup> element.

The [autocorrect](#)<sup>p860</sup> attribute never causes autocorrection to be enabled for [input](#)<sup>p520</sup> elements whose [type](#)<sup>p523</sup> attribute is in one of the [URL](#)<sup>p529</sup>, [E-mail](#)<sup>p530</sup>, or [Password](#)<sup>p531</sup> states. (This behavior is included in the [used autocorrection state](#)<sup>p860</sup> algorithm below.)

The [autocorrect](#) attribute is an enumerated attribute with the following keywords and states:

Keyword	State	Brief description
<a href="#">on</a> (the empty string)	<a href="#">on</a>	The user agent is permitted to automatically correct spelling errors while the user types. Whether spelling is automatically corrected while typing left is for the user agent to decide, and may depend on the element as well as the user's preferences.
<a href="#">off</a>	<a href="#">off</a>	The user agent is not allowed to automatically correct spelling while the user types.

The attribute's [invalid value default](#)<sup>p76</sup> and [missing value default](#)<sup>p76</sup> are both the [on](#)<sup>p860</sup> state.

The [autocorrect](#) getter steps are: return true if the element's [used autocorrection state](#)<sup>p860</sup> is [on](#)<sup>p860</sup> and false if the element's [used autocorrection state](#)<sup>p860</sup> is [off](#)<sup>p860</sup>. The setter steps are: if the given value is true, then the element's [autocorrect](#)<sup>p860</sup> attribute must be set to "on"; otherwise it must be set to "off".

To compute the **used autocorrection state** of an element *element*, run these steps:

1. If *element* is an [input](#)<sup>p520</sup> element whose [type](#)<sup>p523</sup> attribute is in one of the [URL](#)<sup>p529</sup>, [E-mail](#)<sup>p530</sup>, or [Password](#)<sup>p531</sup> states, then return [off](#)<sup>p860</sup>.
2. If the [autocorrect](#)<sup>p860</sup> content attribute is present on *element*, then return the state of the attribute.
3. If *element* is an [autocapitalize-and-autocorrect inheriting element](#)<sup>p514</sup> and has a non-null [form owner](#)<sup>p598</sup>, then return the state of *element*'s [form owner](#)<sup>p598</sup>'s [autocorrect](#)<sup>p860</sup> attribute.
4. Return [on](#)<sup>p860</sup>.

For web developers (non-normative)

**`element . autocorrect`**<sup>p860</sup>

Returns the autocorrection behavior of the element. Note that for [autocapitalize-and-autocorrect inheriting elements](#)<sup>p514</sup> that inherit their state from a [form](#)<sup>p514</sup> element, this will return the autocorrection behavior of the [form](#)<sup>p514</sup> element, but for an element in an editable region, this will not return the autocorrection behavior of the [editing host](#)<sup>p855</sup> (unless this element is, in fact, the [editing host](#)<sup>p855</sup>).

**`element.autocorrectp860 = value`**

Updates the `autocorrectp860` content attribute (and thereby changes the autocorrection behavior of the element).

#### Example

The `inputp520` element in the following example would not allow autocorrection, since it does not have an `autocorrectp860` content attribute and therefore inherits from the `formp514` element, which has an attribute of `"offp860"`. However, the `textareap579` element would allow autocorrection, since it has an `autocorrectp860` content attribute with a value of `"onp860"`.

```
<form autocorrect="off">
  <input type="search">
  <textarea autocorrect="on"></textarea>
</form>
```

### 6.8.9 Input modalities: the `inputmodep861` attribute <sup>§<sup>p86</sup><sub>1</sub></sup>

User agents can support the `inputmodep861` attribute on form controls (such as the value of `textareap579` elements), or in elements in an `editing hostp855` (e.g., using `contenteditablep853`).

The `inputmode` content attribute is an `enumerated attributep76` that specifies what kind of input mechanism would be most helpful for users entering content.

Keyword	Description
<b>none</b>	The user agent should not display a virtual keyboard. This keyword is useful for content that renders its own keyboard control.
<b>text</b>	The user agent should display a virtual keyboard capable of text input in the user's locale.
<b>tel</b>	The user agent should display a virtual keyboard capable of telephone number input. This should including keys for the digits 0 to 9, the "#" character, and the "*" character. In some locales, this can also include alphabetic mnemonic labels (e.g., in the US, the key labeled "2" is historically also labeled with the letters A, B, and C).
<b>url</b>	The user agent should display a virtual keyboard capable of text input in the user's locale, with keys for aiding in the input of <a href="#">URLs</a> , such as that for the "/" and "." characters and for quick input of strings commonly found in domain names such as "www." or ".com".
<b>email</b>	The user agent should display a virtual keyboard capable of text input in the user's locale, with keys for aiding in the input of email addresses, such as that for the "@" character and the "." character.
<b>numeric</b>	The user agent should display a virtual keyboard capable of numeric input. This keyword is useful for PIN entry.
<b>decimal</b>	The user agent should display a virtual keyboard capable of fractional numeric input. Numeric keys and the format separator for the locale should be shown.
<b>search</b>	The user agent should display a virtual keyboard optimized for search.

The `inputMode` IDL attribute must [reflect<sup>p104</sup>](#) the `inputmodep861` content attribute, [limited to only known values<sup>p105</sup>](#).

When `inputmodep861` is unspecified (or is in a state not supported by the user agent), the user agent should determine the default virtual keyboard to be shown. Contextual information such as the input `typep523` or `patternp554` attributes should be used to determine which type of virtual keyboard should be presented to the user.

### 6.8.10 Input modalities: the `enterkeyhintp861` attribute <sup>§<sup>p86</sup><sub>1</sub></sup>

User agents can support the `enterkeyhintp861` attribute on form controls (such as the value of `textareap579` elements), or in elements in an `editing hostp855` (e.g., using `contenteditablep853`).

The `enterkeyhint` content attribute is an `enumerated attributep76` that specifies what action label (or icon) to present for the enter key on virtual keyboards. This allows authors to customize the presentation of the enter key in order to make it more helpful for users.

Keyword	Description
<b>enter</b>	The user agent should present a cue for the operation 'enter', typically inserting a new line.
<b>done</b>	The user agent should present a cue for the operation 'done', typically meaning there is nothing more to input and the input method editor (IME) will be closed.
<b>go</b>	The user agent should present a cue for the operation 'go', typically meaning to take the user to the target of the text they typed.

Keyword	Description
next	The user agent should present a cue for the operation 'next', typically taking the user to the next field that will accept text.
previous	The user agent should present a cue for the operation 'previous', typically taking the user to the previous field that will accept text.
search	The user agent should present a cue for the operation 'search', typically taking the user to the results of searching for the text they have typed.
send	The user agent should present a cue for the operation 'send', typically delivering the text to its target.

The **enterKeyHint** IDL attribute must [reflect](#)<sup>p104</sup> the **enterkeyhint**<sup>p861</sup> content attribute, [limited to only known values](#)<sup>p105</sup>. 

When **enterkeyhint**<sup>p861</sup> is unspecified (or is in a state not supported by the user agent), the user agent should determine the default action label (or icon) to present. Contextual information such as the **inputmode**<sup>p861</sup>, **type**<sup>p523</sup>, or **pattern**<sup>p554</sup> attributes should be used to determine which action label (or icon) to present on the virtual keyboard.

## 6.9 Find-in-page <sup>§ p86 2</sup>

### 6.9.1 Introduction <sup>§ p86 2</sup>

This section defines **find-in-page** — a common user-agent mechanism which allows users to search through the contents of the page for particular information.

Access to the **find-in-page**<sup>p862</sup> feature is provided via a **find-in-page interface**. This is a user-agent provided user interface, which allows the user to specify input and the parameters of the search. This interface can appear as a result of a shortcut or a menu selection.

A combination of text input and settings in the **find-in-page interface**<sup>p862</sup> represents the user **query**. This typically includes the text that the user wants to search for, as well as optional settings (e.g., the ability to restrict the search to whole words only).

The user-agent processes page contents for a given **query**<sup>p862</sup>, and identifies zero or more **matches**, which are content ranges that satisfy the user **query**<sup>p862</sup>.

One of the **matches**<sup>p862</sup> is identified to the user as the **active match**. It is highlighted and scrolled into view. The user can navigate through the **matches**<sup>p862</sup> by advancing the **active match**<sup>p862</sup> using the **find-in-page interface**<sup>p862</sup>.

Issue #3539 tracks standardizing how **find-in-page**<sup>p862</sup> underlies the currently-unspecified `window.find()` API.

### 6.9.2 Interaction with **details**<sup>p637</sup> and **hidden=until-found**<sup>p824</sup> <sup>§ p86 2</sup>

When find-in-page begins searching for matches, all **details**<sup>p637</sup> elements in the page which do not have their **open**<sup>p638</sup> attribute set should have the **skipped contents** of their second slot become accessible, without modifying the **open**<sup>p638</sup> attribute, in order to make find-in-page able to search through it. Similarly, all HTML elements with the **hidden**<sup>p824</sup> attribute in the **hidden until found**<sup>p824</sup> state should have their **skipped contents** become accessible without modifying the **hidden**<sup>p824</sup> attribute in order to make find-in-page able to search through them. After find-in-page finishes searching for matches, the **details**<sup>p637</sup> elements and the elements with the **hidden**<sup>p824</sup> attribute in the **hidden until found**<sup>p824</sup> state should have their contents become skipped again. This entire process must happen synchronously (and so is not observable to users or to author code). [\[CSSCONTAIN\]](#)<sup>p1476</sup>

When find-in-page chooses a new **active match**<sup>p862</sup>, perform the following steps:

- Let *node* be the first node in the **active match**<sup>p862</sup>.
- [Queue a global task](#)<sup>p1125</sup> on the [user interaction task source](#)<sup>p1134</sup> given *node*'s [relevant global object](#)<sup>p1083</sup> to run the following steps:
  - Run the [ancestor details revealing algorithm](#)<sup>p640</sup> on *node*.
  - Run the [ancestor hidden-until-found revealing algorithm](#)<sup>p825</sup> on *node*.

### ⚠Warning!

When find-in-page auto-expands a [details](#)<sup>p637</sup> element like this, it will fire a [toggle](#)<sup>p1472</sup> event. As with the separate [scroll](#) event that find-in-page fires, this event could be used by the page to discover what the user is typing into the find-in-page dialog. If the page creates a tiny scrollable area with the current search term and every possible next character the user could type separated by a gap, and observes which one the browser scrolls to, it can add that character to the search term and update the scrollable area to incrementally build the search term. By wrapping each possible next match in a closed [details](#)<sup>p637</sup> element, the page could listen to [toggle](#)<sup>p1472</sup> events instead of [scroll](#) events. This attack could be addressed for both events by not acting on every character the user types into the find-in-page dialog.

## 6.9.3 Interaction with selection §<sup>p86</sup><sub>3</sub>

The find-in-page process is invoked in the context of a document, and may have an effect on the [selection](#) of that document. Specifically, the range that defines the [active match](#)<sup>p862</sup> can dictate the current selection. These selection updates, however, can happen at different times during the find-in-page process (e.g. upon the [find-in-page interface](#)<sup>p862</sup> dismissal or upon a change in the [active match](#)<sup>p862</sup> range).

## 6.10 Close requests and close watchers §<sup>p86</sup><sub>3</sub>

### 6.10.1 Close requests §<sup>p86</sup><sub>3</sub>

In an [implementation-defined](#) (and likely device-specific) manner, a user can send a **close request** to the user agent. This indicates that the user wishes to close something that is currently being shown on the screen, such as a popover, menu, dialog, picker, or display mode.

#### Example

Some example close requests are:

- The Esc key on desktop platforms.
- The back button or gesture on certain mobile platforms such as Android.
- Any assistive technology's dismiss gesture, such as iOS VoiceOver's two-finger scrub "z" gesture.
- A game controller's canonical "back" button, such as the circle button on a DualShock gamepad.

Whenever the user agent receives a potential close request targeted at a [Document](#)<sup>p130</sup> document, it must [queue a global task](#)<sup>p1125</sup> on the [user interaction task source](#)<sup>p1134</sup> given document's [relevant global object](#)<sup>p1083</sup> to perform the following **close request steps**:

1. If document's [fullscreen element](#) is not null, then:
  1. [Fully exit fullscreen](#) given document's [node navigable](#)<sup>p989</sup>'s [top-level traversable](#)<sup>p990</sup>'s [active document](#)<sup>p989</sup>.
  2. Return.

#### Note

This does not fire any relevant event, such as [keydown](#); it only causes [fullscreenchange](#) to be eventually fired.

2. Optionally, skip to the step labeled [alternative processing](#)<sup>p864</sup>.

#### Note

For example, if the user agent detects user frustration at repeated close request interception by the current web page, it might take this path.

3. Fire any relevant events, per *UI Events* or other relevant specifications. [\[UIEVENTS\]](#)<sup>p1483</sup>

### Example

An example of a relevant event in the *UI Events* model would be the `keydown` event that *UI Events* suggests firing when the user presses the Esc key on their keyboard. On most platforms with keyboards, this is treated as a `close request`<sup>p863</sup>, and so would trigger these `close request steps`<sup>p863</sup>.

### Example

An example of relevant events that are outside of the model given in *UI Events* would be assistive technology synthesizing an Esc `keydown` event when the user sends a `close request`<sup>p863</sup> by using a dismiss gesture.

4. Let *event* be null if no such events are fired, or the `Event` object representing one of the fired events otherwise. If multiple events are fired, which one is chosen is `implementation-defined`.
5. If *event* is not null, and its `canceled flag` is set, then return.
6. If *document* is not `fully active`<sup>p1003</sup>, then return.

### Note

*This step is necessary because, if event is not null, then an event listener might have caused document to no longer be fully active*<sup>p1003</sup>.

7. Let *closedSomething* be the result of `processing close watchers`<sup>p866</sup> on *document*'s `relevant global object`<sup>p1083</sup>.
8. If *closedSomething* is true, then return.
9. *Alternative processing*: Otherwise, there was nothing watching for a `close request`<sup>p863</sup>. The user agent may instead interpret this interaction as some other action, instead of interpreting it as a close request.

On platforms where pressing the Esc key is interpreted as a `close request`<sup>p863</sup>, the user agent must interpret the key being pressed *down* as the close request, instead of the key being released. Thus, in the above algorithm, the "relevant events" that are fired must be the single `keydown` event.

### Example

On platforms where Esc is the `close request`<sup>p863</sup>, the user agent will first fire an appropriately-initialized `keydown` event. If the web developer cancels the event by calling `preventDefault()`, then nothing further happens. But if the event fires without being canceled, then the user agent proceeds to `process close watchers`<sup>p866</sup>.

### Example

On platforms where a back button is a potential `close request`<sup>p863</sup>, no event is involved, so when the back button is pressed, the user agent proceeds directly to `process close watchers`<sup>p866</sup>. If there is an `active`<sup>p865</sup> `close watcher`<sup>p865</sup>, then that will get triggered. If there is not, then the user agent can interpret the back button press in another way, for example as a request to `traverse the history by a delta`<sup>p1028</sup> of `-1`.

## 6.10.2 Close watcher infrastructure <sup>p86</sup>

4

Each `Window`<sup>p922</sup> has a **close watcher manager**, which is a `struct` with the following `items`:

- **Groups**, a `list` of `lists` of `close watchers`<sup>p865</sup>, initially empty.
- **Allowed number of groups**, a number, initially 1.
- **Next user interaction allows a new group**, a boolean, initially true.

Most of the complexity of the `close watcher manager`<sup>p864</sup> comes from anti-abuse protections designed to prevent developers from disabling users' history traversal abilities, for platforms where a `close request`<sup>p863</sup>'s `fallback action`<sup>p864</sup> is the main mechanism of history traversal. In particular:

The grouping of `close watchers`<sup>p865</sup> is designed so that if multiple close watchers are created without `history-action activation`<sup>p830</sup>, they are grouped together, so that a user-triggered `close request`<sup>p863</sup> will close all of the close watchers in a group. This ensures that web developers can't intercept an unlimited number of close requests by creating close watchers; instead they can create a number equal to at most 1 + the number of times the `user activates the page`<sup>p829</sup>.

The [next user interaction allows a new group](#)<sup>p864</sup> boolean encourages web developers to create [close watchers](#)<sup>p865</sup> in a way that is tied to individual [user activations](#)<sup>p829</sup>. Without it, each user activation would increase the [allowed number of groups](#)<sup>p864</sup>, even if the web developer isn't "using" those user activations to create close watchers. In short:

- Allowed: user interaction; create a close watcher in its own group; user interaction; create a close watcher in a second independent group.
- Disallowed: user interaction; user interaction; create a close watcher in its own group; create a close watcher in a second independent group.
- Allowed: user interaction; user interaction; create a close watcher in its own group; create a close watcher grouped with the previous one.

This protection is *not* important for upholding our desired invariant of creating at most (1 + the number of times the [user activates the page](#)<sup>p829</sup>) groups. A determined abuser will just create one close watcher per user interaction, "banking" them for future abuse. But this system causes more predictable behavior for the normal case, and encourages non-abusive developers to create close watchers directly in response to user interactions.

To **notify the close watcher manager about user activation** given a [Window](#)<sup>p922</sup> *window*:

1. Let *manager* be *window*'s [close watcher manager](#)<sup>p864</sup>.
2. If *manager*'s [next user interaction allows a new group](#)<sup>p864</sup> is true, then increment *manager*'s [allowed number of groups](#)<sup>p864</sup>.
3. Set *manager*'s [next user interaction allows a new group](#)<sup>p864</sup> to false.

A **close watcher** is a [struct](#) with the following [items](#):

- A **window**, a [Window](#)<sup>p922</sup>.
- A **cancel action**, an algorithm accepting a boolean argument and returning a boolean. The argument indicates whether or not the cancel action algorithm can prevent the close request from proceeding via the algorithm's return value. If the boolean argument is true, then the algorithm can return either true to indicate that the caller will proceed to the [close action](#)<sup>p865</sup>, or false to indicate that the caller will bail out. If the argument is false, then the return value is always false. This algorithm can never throw an exception.
- A **close action**, an algorithm accepting no arguments and returning nothing. This algorithm can never throw an exception.
- An **is running cancel action** boolean.

A [close watcher](#)<sup>p865</sup> *closeWatcher* is **active** if *closeWatcher*'s [window](#)<sup>p865</sup>'s [close watcher manager](#)<sup>p864</sup> contains any list which contains *closeWatcher*.

To **establish a close watcher** given a [Window](#)<sup>p922</sup> *window*, a list of steps **cancelAction**, and a list of steps **closeAction**:

1. **Assert**: *window*'s [associated Document](#)<sup>p923</sup> is [fully active](#)<sup>p1003</sup>.
2. Let *closeWatcher* be a new [close watcher](#)<sup>p865</sup>, with
 

[window](#)<sup>p865</sup>  
*window*  
[cancel action](#)<sup>p865</sup>  
*cancelAction*  
[close action](#)<sup>p865</sup>  
*closeAction*  
[is running cancel action](#)<sup>p865</sup>  
*false*
3. Let *manager* be *window*'s [close watcher manager](#)<sup>p864</sup>.
4. If *manager*'s [groups](#)<sup>p864</sup>'s [size](#) is less than *manager*'s [allowed number of groups](#)<sup>p864</sup>, then **append** « *closeWatcher* » to *manager*'s [groups](#)<sup>p864</sup>.
5. Otherwise:
  1. **Assert**: *manager*'s [groups](#)<sup>p864</sup>'s [size](#) is at least 1 in this branch, since *manager*'s [allowed number of groups](#)<sup>p864</sup> is

always at least 1.

2. [Append](#) `closeWatcher` to `manager's groupsp864`'s last `item`.
6. Set `manager's next user interaction allows a new groupp864` to true.
7. Return `closeWatcher`.

To **request to close** a `close_watcherp865` `closeWatcher`:

1. If `closeWatcher` `is not activep865`, then return true.
2. If `closeWatcher's is running cancel actionp865` is true, then return true.
3. Let `window` be `closeWatcher's windowp865`.
4. If `window's associated Documentp923` is not `fully activep1003`, then return true.
5. Let `canPreventClose` be true if `window's close_watcher managerp864's groupsp864's size` is less than `window's close_watcher managerp864's allowed number of groupsp864`, and `window` has `history-action activationp830`; otherwise false.
6. Set `closeWatcher's is running cancel actionp865` to true.
7. Let `shouldContinue` be the result of running `closeWatcher's cancel actionp865` given `canPreventClose`.
8. Set `closeWatcher's is running cancel actionp865` to false.
9. If `shouldContinue` is false, then:
  1. [Assert](#): `canPreventClose` is true.
  2. [Consume history-action user activation<sup>p831</sup>](#) given `window`.
  3. Return false.

#### Note

*Note that since these substeps [consume history-action user activation<sup>p831</sup>](#), [requesting to close<sup>p866</sup> a close\\_watcher<sup>p865</sup>](#) twice without any intervening [user activation<sup>p829</sup>](#) will result in `canPreventClose` being false the second time.*

10. [Close<sup>p866</sup>](#) `closeWatcher`.
11. Return true.

To **close** a `close_watcherp865` `closeWatcher`:

1. If `closeWatcher` `is not activep865`, then return.
2. If `closeWatcher's windowp865's associated Documentp923` is not `fully activep1003`, then return.
3. [Destroy<sup>p866</sup>](#) `closeWatcher`.
4. Run `closeWatcher's close actionp865`.

To **destroy** a `close_watcherp865` `closeWatcher`:

1. Let `manager` be `closeWatcher's windowp865's close_watcher managerp864`.
2. [For each](#) group of `manager's groupsp864`: [remove](#) `closeWatcher` from group.
3. [Remove](#) any item from `manager's groupsp864` that `is empty`.

To **process close watchers** given a `Windowp922` `window`:

1. Let `processedACloseWatcher` be false.
2. If `window's close_watcher managerp864's groupsp864` is not empty:
  1. Let `group` be the last `item` in `window's close_watcher managerp864's groupsp864`.

2. [For each](#) [closeWatcher](#) of *group*, in reverse order:
  1. Set *processedACloseWatcher* to true.
  2. Let *shouldProceed* be the result of [requesting to close](#)<sup>p866</sup> *closeWatcher*.
  3. If *shouldProceed* is false, then [break](#).
3. If *window*'s [close watcher manager](#)<sup>p864</sup>'s [allowed number of groups](#)<sup>p864</sup> is greater than 1, decrement it by 1.
4. Return *processedACloseWatcher*.

### 6.10.3 The [CloseWatcher](#)<sup>p867</sup> interface §<sup>p86</sup><sub>7</sub>

IDL

```
[Exposed=Window]
interface CloseWatcher : EventTarget {
  constructor(optional CloseWatcherOptions options = {});

  undefined requestClose();
  undefined close();
  undefined destroy();

  attribute EventHandler oncancel;
  attribute EventHandler onclose;
};

dictionary CloseWatcherOptions {
  AbortSignal signal;
};
```

#### For web developers (non-normative)

```
watcher = new CloseWatcherp868()
watcher = new CloseWatcherp868({ signalp867 })
```

Creates a new [CloseWatcher](#)<sup>p867</sup> instance.

If the [signal](#)<sup>p867</sup> option is provided, then *watcher* can be destroyed (as if by [watcher.destroy\(\)](#)<sup>p868</sup>) by aborting the given [AbortSignal](#).

If any [close watcher](#)<sup>p865</sup> is already active, and the [Window](#)<sup>p922</sup> does not have [history-action activation](#)<sup>p830</sup>, then the resulting [CloseWatcher](#)<sup>p867</sup> will be closed together with that already-active [close watcher](#)<sup>p865</sup> in response to any [close request](#)<sup>p863</sup>. (This already-active [close watcher](#)<sup>p865</sup> does not necessarily have to be a [CloseWatcher](#)<sup>p867</sup> object; it could be a modal [dialog](#)<sup>p646</sup> element, or a popover generated by an element with the [popover](#)<sup>p886</sup> attribute.)

```
watcher.requestClosep868()
```

Acts as if a [close request](#)<sup>p863</sup> was sent targeting *watcher*, by first firing a [cancel](#)<sup>p1471</sup> event, and if that event is not canceled with [preventDefault\(\)](#), proceeding to fire a [close](#)<sup>p1471</sup> event before deactivating the close watcher as if [watcher.destroy\(\)](#)<sup>p868</sup> was called.

This is a helper utility that can be used to consolidate cancelation and closing logic into the [cancel](#)<sup>p1471</sup> and [close](#)<sup>p1471</sup> event handlers, by having all non-[close request](#)<sup>p863</sup> closing affordances call this method.

```
watcher.closep868()
```

Immediately fires the [close](#)<sup>p1471</sup> event, and then deactivates the close watcher as if [watcher.destroy\(\)](#)<sup>p868</sup> was called.

This is a helper utility that can be used trigger the closing logic into the [close](#)<sup>p1471</sup> event handler, skipping any logic in the [cancel](#)<sup>p1471</sup> event handler.

```
watcher.destroyp868()
```

Deactivates *watcher*, so that it will no longer receive [close](#)<sup>p1471</sup> events and so that new independent [CloseWatcher](#)<sup>p867</sup> instances can be constructed.

This is intended to be called if the relevant UI element is torn down in some other way than being closed.

Each [CloseWatcher](#)<sup>p867</sup> instance has an **internal close watcher**, which is a [close watcher](#)<sup>p865</sup>.

The **new CloseWatcher(*options*)** constructor steps are:

1. If [this's relevant global object](#)<sup>p1083</sup>'s [associated Document](#)<sup>p923</sup> is not [fully active](#)<sup>p1003</sup>, then throw an **"InvalidStateError"** [DOMException](#).
2. Let *closeWatcher* be the result of [establishing a close watcher](#)<sup>p865</sup> given [this's relevant global object](#)<sup>p1083</sup>, with:
  - [cancelAction](#)<sup>p865</sup> given *canPreventClose* being to return the result of [firing an event](#) named [cancel](#)<sup>p1471</sup> at [this](#), with the [cancelable](#) attribute initialized to *canPreventClose*.
  - [closeAction](#)<sup>p865</sup> being to [fire an event](#) named [close](#)<sup>p1471</sup> at [this](#).
3. If [options\["signal"\]](#)<sup>p867</sup> [exists](#), then:
  1. If [options\["signal"\]](#)<sup>p867</sup> is [aborted](#), then [destroy](#)<sup>p866</sup> *closeWatcher*.
  2. [Add](#) the following steps to [options\["signal"\]](#)<sup>p867</sup>:
    1. [Destroy](#)<sup>p866</sup> *closeWatcher*.
4. Set [this's internal close watcher](#)<sup>p867</sup> to *closeWatcher*.

The **requestClose()** method steps are to [request to close](#)<sup>p866</sup> [this's internal close watcher](#)<sup>p867</sup>.

The **close()** method steps are to [close](#)<sup>p866</sup> [this's internal close watcher](#)<sup>p867</sup>.

The **destroy()** method steps are to [destroy](#)<sup>p866</sup> [this's internal close watcher](#)<sup>p867</sup>.

The following are the [event handlers](#)<sup>p1136</sup> (and their corresponding [event handler event types](#)<sup>p1139</sup>) that must be supported, as [event handler IDL attributes](#)<sup>p1137</sup>, by all objects implementing the [CloseWatcher](#)<sup>p867</sup> interface:

<a href="#">Event handler</a> <sup>p1136</sup>	<a href="#">Event handler event type</a> <sup>p1139</sup>
<a href="#">oncancel</a>	<a href="#">cancel</a> <sup>p1471</sup>
<a href="#">onclose</a>	<a href="#">close</a> <sup>p1471</sup>

#### Example

If one wanted to implement a custom picker control, which closed itself on a user-provided [close request](#)<sup>p863</sup> as well as when a close button is pressed, the following code shows how one would use the [CloseWatcher](#)<sup>p867</sup> API to process close requests:

```
const watcher = new CloseWatcher();
const picker = setUpAndShowPickerDOMElement();

let chosenValue = null;

watcher.onclose = () => {
  chosenValue = picker.querySelector('input').value;
  picker.remove();
};

picker.querySelector('.close-button').onclick = () => watcher.requestClose();
```

Note how the logic to gather the chosen value is centralized in the [CloseWatcher](#)<sup>p867</sup> object's [close](#)<sup>p1471</sup> event handler, with the [click](#) event handler for the close button delegating to that logic by calling [requestClose\(\)](#)<sup>p868</sup>.

#### Example

The [cancel](#)<sup>p1471</sup> event on [CloseWatcher](#)<sup>p867</sup> objects can be used to prevent the [close](#)<sup>p1471</sup> event from firing, and the [CloseWatcher](#)<sup>p867</sup> from being destroying. A typical use case is as follows:

```
watcher.oncancel = async (e) => {
  if (hasUnsavedData && e.cancelable) {
    e.preventDefault();
  }
};
```

```
const userReallyWantsToClose = await askForConfirmation("Are you sure you want to close?");
if (userReallyWantsToClose) {
  hasUnsavedData = false;
  watcher.close();
}
}
};
```

For abuse prevention purposes, this event is only [cancelable](#) if the page has [history-action activation](#)<sup>p830</sup>, which will be lost after any given [close request](#)<sup>p863</sup>. This ensures that if the user sends a close request twice in a row without any intervening user activation, the request definitely succeeds; the second request ignores any [cancel](#)<sup>p1471</sup> event handler's attempt to call [preventDefault\(\)](#) and proceeds to close the [CloseWatcher](#)<sup>p867</sup>.

Combined, the above two examples show how [requestClose\(\)](#)<sup>p868</sup> and [close\(\)](#)<sup>p868</sup> differ. Because we used [requestClose\(\)](#)<sup>p868</sup> in the [click](#) event handler for the close button, clicking that button will trigger the [CloseWatcher](#)<sup>p867</sup>'s [cancel](#)<sup>p1471</sup> event, and thus potentially ask the user for confirmation if there is unsaved data. If we had used [close\(\)](#)<sup>p868</sup>, then this check would be skipped. Sometimes that is appropriate, but usually [requestClose\(\)](#)<sup>p868</sup> is the better option for user-triggered close requests.

#### Example

In addition to the [user activation](#)<sup>p829</sup> restrictions for [cancel](#)<sup>p1471</sup> events, there is a more subtle form of user activation gating for [CloseWatcher](#)<sup>p867</sup> construction. If one creates more than one [CloseWatcher](#)<sup>p867</sup> without user activation, then the newly-created one will get grouped together with the most-recently-created [close watcher](#)<sup>p865</sup>, so that a single [close request](#)<sup>p863</sup> will close them both:

```
window.onload = () => {
  // This will work as normal: it is the first close watcher created without user activation.
  (new CloseWatcher()).onclose = () => { /* ... */ };
};

button1.onclick = () => {
  // This will work as normal: the button click counts as user activation.
  (new CloseWatcher()).onclose = () => { /* ... */ };
};

button2.onclick = () => {
  // These will be grouped together, and both will close in response to a single close request.
  (new CloseWatcher()).onclose = () => { /* ... */ };
  (new CloseWatcher()).onclose = () => { /* ... */ };
};
```

This means that calling [destroy\(\)](#)<sup>p868</sup>, [close\(\)](#)<sup>p868</sup>, or [requestClose\(\)](#)<sup>p868</sup> properly is important. Doing so is the only way to get back the "free" ungrouped close watcher slot. Such close watchers created without user activation are useful for cases like session inactivity timeout dialogs or urgent notifications of server-triggered events, which are not generated in response to user activation.

## 6.11 Drag and drop §<sup>p886</sup><sub>9</sub>

This section defines an event-based drag-and-drop mechanism.

This specification does not define exactly what a *drag-and-drop operation* actually is.

On a visual medium with a pointing device, a drag operation could be the default action of a [mousedown](#) event that is followed by a series of [mousemove](#) events, and the drop could be triggered by the mouse being released.

When using an input modality other than a pointing device, users would probably have to explicitly indicate their intention to perform a drag-and-drop operation, stating what they wish to drag and where they wish to drop it, respectively.

However it is implemented, drag-and-drop operations must have a starting point (e.g. where the mouse was clicked, or the start of the selection or element that was selected for the drag), may have any number of intermediate steps (elements that the mouse moves

over during a drag, or elements that the user picks as possible drop points as they cycle through possibilities), and must either have an end point (the element above which the mouse button was released, or the element that was finally selected), or be canceled. The end point must be the last element selected as a possible drop point before the drop occurs (so if the operation is not canceled, there must be at least one element in the middle step).

### 6.11.1 Introduction <sup>§ p87</sup><sub>0</sub>

*This section is non-normative.*

To make an element draggable, give the element a [draggable<sup>p885</sup>](#) attribute, and set an event listener for [dragstart<sup>p884</sup>](#) that stores the data being dragged.

The event handler typically needs to check that it's not a text selection that is being dragged, and then needs to store data into the [DataTransfer<sup>p872</sup>](#) object and set the allowed effects (copy, move, link, or some combination).

For example:

```
<p>What fruits do you like?</p>
<ol ondragstart="dragStartHandler(event)">
  <li draggable="true" data-value="fruit-apple">Apples</li>
  <li draggable="true" data-value="fruit-orange">Oranges</li>
  <li draggable="true" data-value="fruit-pear">Pears</li>
</ol>
<script>
  var internalDNDType = 'text/x-example'; // set this to something specific to your site
  function dragStartHandler(event) {
    if (event.target instanceof HTMLLIElement) {
      // use the element's data-value="" attribute as the value to be moving:
      event.dataTransfer.setData(internalDNDType, event.target.dataset.value);
      event.dataTransfer.effectAllowed = 'move'; // only allow moves
    } else {
      event.preventDefault(); // don't allow selection to be dragged
    }
  }
</script>
```

To accept a drop, the drop target has to listen to the following events:

1. The [dragenter<sup>p884</sup>](#) event handler reports whether or not the drop target is potentially willing to accept the drop, by canceling the event.
2. The [dragover<sup>p884</sup>](#) event handler specifies what feedback will be shown to the user, by setting the [dropEffect<sup>p874</sup>](#) attribute of the [DataTransfer<sup>p872</sup>](#) associated with the event. This event also needs to be canceled.
3. The [drop<sup>p885</sup>](#) event handler has a final chance to accept or reject the drop. If the drop is accepted, the event handler must perform the drop operation on the target. This event needs to be canceled, so that the [dropEffect<sup>p874</sup>](#) attribute's value can be used by the source. Otherwise, the drop operation is rejected.

For example:

```
<p>Drop your favorite fruits below:</p>
<ol ondragenter="dragEnterHandler(event)" ondragover="dragOverHandler(event)"
  ondrop="dropHandler(event)">
</ol>
<script>
  var internalDNDType = 'text/x-example'; // set this to something specific to your site
  function dragEnterHandler(event) {
    var items = event.dataTransfer.items;
    for (var i = 0; i < items.length; ++i) {
      var item = items[i];
```

```

    if (item.kind == 'string' && item.type == internalDNDType) {
        event.preventDefault();
        return;
    }
}
}
function dragOverHandler(event) {
    event.dataTransfer.dropEffect = 'move';
    event.preventDefault();
}
function dropHandler(event) {
    var li = document.createElement('li');
    var data = event.dataTransfer.getData(internalDNDType);
    if (data == 'fruit-apple') {
        li.textContent = 'Apples';
    } else if (data == 'fruit-orange') {
        li.textContent = 'Oranges';
    } else if (data == 'fruit-pear') {
        li.textContent = 'Pears';
    } else {
        li.textContent = 'Unknown Fruit';
    }
    event.target.appendChild(li);
}
</script>

```

To remove the original element (the one that was dragged) from the display, the [dragend<sup>p885</sup>](#) event can be used.

For our example here, that means updating the original markup to handle that event:

```

<p>What fruits do you like?</p>
<ol ondragstart="dragStartHandler(event)" ondragend="dragEndHandler(event)">
  ...as before...
</ol>
<script>
  function dragStartHandler(event) {
    // ...as before...
  }
  function dragEndHandler(event) {
    if (event.dataTransfer.dropEffect == 'move') {
      // remove the dragged element
      event.target.parentNode.removeChild(event.target);
    }
  }
</script>

```

## 6.11.2 The drag data store <sup>§p87</sup><sub>1</sub>

The data that underlies a drag-and-drop operation, known as the **drag data store**, consists of the following information:

- A **drag data store item list**, which is a list of items representing the dragged data, each consisting of the following information:

### ***The drag data item kind***

The kind of data:

#### ***Text***

Text.

## File

Binary data with a filename.

### The drag data item type string

A Unicode string giving the type or format of the data, generally given by a [MIME type](#). Some values that are not [MIME types](#) are special-cased for legacy reasons. The API does not enforce the use of [MIME types](#); other values can be used as well. In all cases, however, the values are all [converted to ASCII lowercase](#) by the API.

There is a limit of one [text item](#) per [item type string](#)<sup>p872</sup>.

### The actual data

A Unicode or binary string, in some cases with a filename (itself a Unicode string), as per [the drag data item kind](#)<sup>p871</sup>.

The [drag data store item list](#)<sup>p871</sup> is ordered in the order that the items were added to the list; most recently added last.

- The following information, used to generate the UI feedback during the drag:
  - User-agent-defined default feedback information, known as the **drag data store default feedback**.
  - Optionally, a bitmap image and the coordinate of a point within that image, known as the **drag data store bitmap** and **drag data store hot spot coordinate**.
- A **drag data store mode**, which is one of the following:

#### Read/write mode

For the [dragstart](#)<sup>p884</sup> event. New data can be added to the [drag data store](#)<sup>p871</sup>.

#### Read-only mode

For the [drop](#)<sup>p885</sup> event. The list of items representing dragged data can be read, including the data. No new data can be added.

#### Protected mode

For all other events. The formats and kinds in the [drag data store](#)<sup>p871</sup> list of items representing dragged data can be enumerated, but the data itself is unavailable and no new data can be added.

- A **drag data store allowed effects state**, which is a string.

When a [drag data store](#)<sup>p871</sup> is **created**, it must be initialized such that its [drag data store item list](#)<sup>p871</sup> is empty, it has no [drag data store default feedback](#)<sup>p872</sup>, it has no [drag data store bitmap](#)<sup>p872</sup> and [drag data store hot spot coordinate](#)<sup>p872</sup>, its [drag data store mode](#)<sup>p872</sup> is [protected mode](#)<sup>p872</sup>, and its [drag data store allowed effects state](#)<sup>p872</sup> is the string "[uninitialized](#)<sup>p874</sup>".

## 6.11.3 The [DataTransfer](#)<sup>p872</sup> interface §<sup>p87</sup><sub>2</sub>

[DataTransfer](#)<sup>p872</sup> objects are used to expose the [drag data store](#)<sup>p871</sup> that underlies a drag-and-drop operation.

```
IDL [Exposed=Window]
interface DataTransfer {
  constructor();

  attribute DOMString dropEffect;
  attribute DOMString effectAllowed;

  [SameObject] readonly attribute DataTransferItemList items;

  undefined setDragImage(Element image, long x, long y);

  /* old interface */
  readonly attribute FrozenArray<DOMString> types;
  DOMString getData(DOMString format);
  undefined setData(DOMString format, DOMString data);
  undefined clearData(optional DOMString format);
```

```
[SameObject] readonly attribute FileList files;
};
```

For web developers (non-normative)

**`dataTransfer = new DataTransferp873()`**

Creates a new `DataTransferp872` object with an empty `drag data storep871`.

**`dataTransfer.dropEffectp874 [ = value ]`**

Returns the kind of operation that is currently selected. If the kind of operation isn't one of those that is allowed by the `effectAllowedp874` attribute, then the operation will fail.

Can be set, to change the selected operation.

The possible values are "`nonep874`", "`copyp874`", "`linkp874`", and "`movep874`".

**`dataTransfer.effectAllowedp874 [ = value ]`**

Returns the kinds of operations that are to be allowed.

Can be set (during the `dragstartp884` event), to change the allowed operations.

The possible values are "`nonep874`", "`copyp874`", "`copyLinkp874`", "`copyMovep874`", "`linkp874`", "`linkMovep874`", "`movep874`", "`allp874`", and "`uninitializedp874`".

**`dataTransfer.itemsp874`**

Returns a `DataTransferItemListp875` object, with the drag data.

**`dataTransfer.setDragImagep874(element, x, y)`**

Uses the given element to update the drag feedback, replacing any previously specified feedback.

**`dataTransfer.typesp874`**

Returns a `frozen array` listing the formats that were set in the `dragstartp884` event. In addition, if any files are being dragged, then one of the types will be the string "Files".

**`data = dataTransfer.getDatap874(format)`**

Returns the specified data. If there is no such data, returns the empty string.

**`dataTransfer.setDatap874(format, data)`**

Adds the specified data.

**`dataTransfer.clearDatap875([ format ])`**

Removes the data of the specified formats. Removes all data if the argument is omitted.

**`dataTransfer.filesp875`**

Returns a `FileList` of the files being dragged, if any.

`DataTransferp872` objects that are created as part of `drag-and-drop eventsp884` are only valid while those events are being fired.

A `DataTransferp872` object is associated with a `drag data storep871` while it is valid.

A `DataTransferp872` object has an associated **types array**, which is a `FrozenArray<DOMString>`, initially empty. When the contents of the `DataTransferp872` object's `drag data store item listp871` change, or when the `DataTransferp872` object becomes no longer associated with a `drag data storep871`, run the following steps:

1. Let *L* be an empty sequence.
2. If the `DataTransferp872` object is still associated with a `drag data storep871`, then:
  1. For each item in the `DataTransferp872` object's `drag data store item listp871` whose `kindp871` is *text*, add an entry to *L* consisting of the item's `type stringp872`.
  2. If there are any items in the `DataTransferp872` object's `drag data store item listp871` whose `kindp871` is *File*, then add an entry to *L* consisting of the string "Files". (This value can be distinguished from the other values because it is not lowercase.)
3. Set the `DataTransferp872` object's `types arrayp873` to the result of `creating a frozen array` from *L*.

The `DataTransfer()` constructor, when invoked, must return a newly created `DataTransferp872` object initialized as follows:

1. Set the [drag\\_data\\_store<sup>p871</sup>](#)'s [item\\_list<sup>p871</sup>](#) to be an empty list.
2. Set the [drag\\_data\\_store<sup>p871</sup>](#)'s [mode<sup>p872</sup>](#) to [read/write mode<sup>p872</sup>](#).
3. Set the [dropEffect<sup>p874</sup>](#) and [effectAllowed<sup>p874</sup>](#) to "none".

The **dropEffect** attribute controls the drag-and-drop feedback that the user is given during a drag-and-drop operation. When the [DataTransfer<sup>p872</sup>](#) object is created, the [dropEffect<sup>p874</sup>](#) attribute is set to a string value. On getting, it must return its current value. On setting, if the new value is one of "none", "copy", "link", or "move", then the attribute's current value must be set to the new value. Other values must be ignored.

The **effectAllowed** attribute is used in the drag-and-drop processing model to initialize the [dropEffect<sup>p874</sup>](#) attribute during the [dragenter<sup>p884</sup>](#) and [dragover<sup>p884</sup>](#) events. When the [DataTransfer<sup>p872</sup>](#) object is created, the [effectAllowed<sup>p874</sup>](#) attribute is set to a string value. On getting, it must return its current value. On setting, if [drag\\_data\\_store<sup>p871</sup>](#)'s [mode<sup>p872</sup>](#) is the [read/write mode<sup>p872</sup>](#) and the new value is one of "none", "copy", "copyLink", "copyMove", "link", "linkMove", "move", "all", or "uninitialized", then the attribute's current value must be set to the new value. Otherwise, it must be left unchanged.

The **items** attribute must return a [DataTransferItemList<sup>p875</sup>](#) object associated with the [DataTransfer<sup>p872</sup>](#) object.

The **setDragImage(image, x, y)** method must run the following steps:

1. If the [DataTransfer<sup>p872</sup>](#) object is no longer associated with a [drag\\_data\\_store<sup>p871</sup>](#), return. Nothing happens.
2. If the [drag\\_data\\_store<sup>p871</sup>](#)'s [mode<sup>p872</sup>](#) is not the [read/write mode<sup>p872</sup>](#), return. Nothing happens.
3. If *image* is an [img<sup>p346</sup>](#) element, then set the [drag\\_data\\_store bitmap<sup>p872</sup>](#) to the element's image (at its [natural size](#)); otherwise, set the [drag\\_data\\_store bitmap<sup>p872</sup>](#) to an image generated from the given element (the exact mechanism for doing so is not currently specified).
4. Set the [drag\\_data\\_store hot spot coordinate<sup>p872</sup>](#) to the given x, y coordinate.

The **types** attribute must return this [DataTransfer<sup>p872</sup>](#) object's [types array<sup>p873</sup>](#).

The **getData(format)** method must run the following steps:

1. If the [DataTransfer<sup>p872</sup>](#) object is no longer associated with a [drag\\_data\\_store<sup>p871</sup>](#), then return the empty string.
2. If the [drag\\_data\\_store<sup>p871</sup>](#)'s [mode<sup>p872</sup>](#) is the [protected mode<sup>p872</sup>](#), then return the empty string.
3. Let *format* be the first argument, [converted to ASCII lowercase](#).
4. Let *convert-to-URL* be false.
5. If *format* equals "text", change it to "text/plain".
6. If *format* equals "url", change it to "text/uri-list" and set *convert-to-URL* to true.
7. If there is no item in the [drag\\_data\\_store item list<sup>p871</sup>](#) whose [kind<sup>p871</sup>](#) is *text* and whose [type string<sup>p872</sup>](#) is equal to *format*, return the empty string.
8. Let *result* be the data of the item in the [drag\\_data\\_store item list<sup>p871</sup>](#) whose [kind<sup>p871</sup>](#) is *Plain Unicode string* and whose [type string<sup>p872</sup>](#) is equal to *format*.
9. If *convert-to-URL* is true, then parse *result* as appropriate for text/uri-list data, and then set *result* to the first URL from the list, if any, or the empty string otherwise. [\[RFC2483\]<sup>p1481</sup>](#)
10. Return *result*.

The **setData(format, data)** method must run the following steps:

1. If the [DataTransfer<sup>p872</sup>](#) object is no longer associated with a [drag\\_data\\_store<sup>p871</sup>](#), return. Nothing happens.
2. If the [drag\\_data\\_store<sup>p871</sup>](#)'s [mode<sup>p872</sup>](#) is not the [read/write mode<sup>p872</sup>](#), return. Nothing happens.
3. Let *format* be the first argument, [converted to ASCII lowercase](#).
4. If *format* equals "text", change it to "text/plain".  
If *format* equals "url", change it to "text/uri-list".

- Remove the item in the [drag\\_data\\_store\\_item\\_list](#)<sup>p871</sup> whose [kind](#)<sup>p871</sup> is text and whose [type\\_string](#)<sup>p872</sup> is equal to *format*, if there is one.
- Add an item to the [drag\\_data\\_store\\_item\\_list](#)<sup>p871</sup> whose [kind](#)<sup>p871</sup> is text, whose [type\\_string](#)<sup>p872</sup> is equal to *format*, and whose data is the string given by the method's second argument.

The **clearData(*format*)** method must run the following steps:

- If the [DataTransfer](#)<sup>p872</sup> object is no longer associated with a [drag\\_data\\_store](#)<sup>p871</sup>, return. Nothing happens.
- If the [drag\\_data\\_store](#)<sup>p871</sup>'s [mode](#)<sup>p872</sup> is not the [read/write\\_mode](#)<sup>p872</sup>, return. Nothing happens.
- If the method was called with no arguments, remove each item in the [drag\\_data\\_store\\_item\\_list](#)<sup>p871</sup> whose [kind](#)<sup>p871</sup> is *Plain Unicode string*, and return.
- Set *format* to *format*, [converted to ASCII lowercase](#).
- If *format* equals "text", change it to "text/plain".  
If *format* equals "url", change it to "text/uri-list".
- Remove the item in the [drag\\_data\\_store\\_item\\_list](#)<sup>p871</sup> whose [kind](#)<sup>p871</sup> is text and whose [type\\_string](#)<sup>p872</sup> is equal to *format*, if there is one.

#### Note

The **clearData()**<sup>p875</sup> method does not affect whether any files were included in the drag, so the [types](#)<sup>p874</sup> attribute's list might still not be empty after calling **clearData()**<sup>p875</sup> (it would still contain the "Files" string if any files were included in the drag).

The **files** attribute must return a [live](#)<sup>p47</sup> [FileList](#) sequence consisting of [File](#) objects representing the files found by the following steps. Furthermore, for a given [FileList](#) object and a given underlying file, the same [File](#) object must be used each time.

- Start with an empty list *L*.
- If the [DataTransfer](#)<sup>p872</sup> object is no longer associated with a [drag\\_data\\_store](#)<sup>p871</sup>, the [FileList](#) is empty. Return the empty list *L*.
- If the [drag\\_data\\_store](#)<sup>p871</sup>'s [mode](#)<sup>p872</sup> is the [protected\\_mode](#)<sup>p872</sup>, return the empty list *L*.
- For each item in the [drag\\_data\\_store\\_item\\_list](#)<sup>p871</sup> whose [kind](#)<sup>p871</sup> is *File*, add the item's data (the file, in particular its name and contents, as well as its [type](#)<sup>p872</sup>) to the list *L*.
- The files found by these steps are those in the list *L*.

#### Note

This version of the API does not expose the types of the files during the drag.

### 6.11.3.1 The [DataTransferItemList](#)<sup>p875</sup> interface § p875

Each [DataTransfer](#)<sup>p872</sup> object is associated with a [DataTransferItemList](#)<sup>p875</sup> object.

```
IDL
[Exposed=Window]
interface DataTransferItemList {
  readonly attribute unsigned long length;
  getter DataTransferItem (unsigned long index);
  DataTransferItem? add(DOMString data, DOMString type);
  DataTransferItem? add(File data);
  undefined remove(unsigned long index);
  undefined clear();
};
```

For web developers (non-normative)

**`items.length`**<sup>p876</sup>

Returns the number of items in the [drag data store](#)<sup>p871</sup>.

**`items[index]`**

Returns the [DataTransferItem](#)<sup>p877</sup> object representing the *indexth* entry in the [drag data store](#)<sup>p871</sup>.

**`items.remove`**<sup>p876</sup>(*index*)

Removes the *indexth* entry in the [drag data store](#)<sup>p871</sup>.

**`items.clear`**<sup>p876</sup>()

Removes all the entries in the [drag data store](#)<sup>p871</sup>.

**`items.add`**<sup>p876</sup>(*data*)

**`items.add`**<sup>p876</sup>(*data*, *type*)

Adds a new entry for the given data to the [drag data store](#)<sup>p871</sup>. If the data is plain text then a *type* string has to be provided also.

While the [DataTransferItemList](#)<sup>p875</sup> object's [DataTransfer](#)<sup>p872</sup> object is associated with a [drag data store](#)<sup>p871</sup>, the [DataTransferItemList](#)<sup>p875</sup> object's *mode* is the same as the [drag data store mode](#)<sup>p872</sup>. When the [DataTransferItemList](#)<sup>p875</sup> object's [DataTransfer](#)<sup>p872</sup> object is *not* associated with a [drag data store](#)<sup>p871</sup>, the [DataTransferItemList](#)<sup>p875</sup> object's *mode* is the *disabled mode*. The [drag data store](#)<sup>p871</sup> referenced in this section (which is used only when the [DataTransferItemList](#)<sup>p875</sup> object is not in the *disabled mode*) is the [drag data store](#)<sup>p871</sup> with which the [DataTransferItemList](#)<sup>p875</sup> object's [DataTransfer](#)<sup>p872</sup> object is associated.

The **length** attribute must return zero if the object is in the *disabled mode*; otherwise it must return the number of items in the [drag data store item list](#)<sup>p871</sup>.

When a [DataTransferItemList](#)<sup>p875</sup> object is not in the *disabled mode*, its [supported property indices](#) are the [indices](#) of the [drag data store item list](#)<sup>p871</sup>.

To [determine the value of an indexed property](#) *i* of a [DataTransferItemList](#)<sup>p875</sup> object, the user agent must return a [DataTransferItem](#)<sup>p877</sup> object representing the *i*th item in the [drag data store](#)<sup>p871</sup>. The same object must be returned each time a particular item is obtained from this [DataTransferItemList](#)<sup>p875</sup> object. The [DataTransferItem](#)<sup>p877</sup> object must be associated with the same [DataTransfer](#)<sup>p872</sup> object as the [DataTransferItemList](#)<sup>p875</sup> object when it is first created.

The **add()** method must run the following steps:

1. If the [DataTransferItemList](#)<sup>p875</sup> object is not in the [read/write mode](#)<sup>p872</sup>, return null.
2. Jump to the appropriate set of steps from the following list:

↪ **If the first argument to the method is a string**

If there is already an item in the [drag data store item list](#)<sup>p871</sup> whose [kind](#)<sup>p871</sup> is *text* and whose [type string](#)<sup>p872</sup> is equal to the value of the method's second argument, [converted to ASCII lowercase](#), then throw a **"NotSupportedError"** [DOMException](#).

Otherwise, add an item to the [drag data store item list](#)<sup>p871</sup> whose [kind](#)<sup>p871</sup> is *text*, whose [type string](#)<sup>p872</sup> is equal to the value of the method's second argument, [converted to ASCII lowercase](#), and whose data is the string given by the method's first argument.

↪ **If the first argument to the method is a File**

Add an item to the [drag data store item list](#)<sup>p871</sup> whose [kind](#)<sup>p871</sup> is *File*, whose [type string](#)<sup>p872</sup> is the *type* of the *File*, [converted to ASCII lowercase](#), and whose data is the same as the *File*'s data.

3. [Determine the value of the indexed property](#)<sup>p876</sup> corresponding to the newly added item, and return that value (a newly created [DataTransferItem](#)<sup>p877</sup> object).

The **remove(index)** method must run these steps:

1. If the [DataTransferItemList](#)<sup>p875</sup> object is not in the [read/write mode](#)<sup>p872</sup>, throw an **"InvalidStateError"** [DOMException](#).
2. If the [drag data store](#)<sup>p871</sup> does not contain an *indexth* item, then return.
3. Remove the *indexth* item from the [drag data store](#)<sup>p871</sup>.

The **clear()** method, if the [DataTransferItemList](#)<sup>p875</sup> object is in the [read/write mode](#)<sup>p872</sup>, must remove all the items from the [drag](#)

[data store](#)<sup>p871</sup>. Otherwise, it must do nothing.

### 6.11.3.2 The [DataTransferItem](#)<sup>p877</sup> interface §<sup>p87</sup><sub>7</sub>

Each [DataTransferItem](#)<sup>p877</sup> object is associated with a [DataTransfer](#)<sup>p872</sup> object.

```
IDL [Exposed=Window]
interface DataTransferItem {
    readonly attribute DOMString kind;
    readonly attribute DOMString type;
    undefined getAsString(FunctionStringCallback? _callback);
    File? getAsFile();
};

callback FunctionStringCallback = undefined (DOMString data);
```

For web developers (non-normative)

**[item.kind](#)**<sup>p877</sup>

Returns [the drag data item kind](#)<sup>p871</sup>, one of: "string", "file".

**[item.type](#)**<sup>p877</sup>

Returns [the drag data item type string](#)<sup>p872</sup>.

**[item.getAsString](#)**<sup>p877</sup>(*callback*)

Invokes the callback with the string data as the argument, if [the drag data item kind](#)<sup>p871</sup> is text.

***file* = [item.getAsFile](#)**<sup>p877</sup>()

Returns a [File](#) object, if [the drag data item kind](#)<sup>p871</sup> is File.

While the [DataTransferItem](#)<sup>p877</sup> object's [DataTransfer](#)<sup>p872</sup> object is associated with a [drag data store](#)<sup>p871</sup> and that [drag data store](#)<sup>p871</sup>'s [drag data store item list](#)<sup>p871</sup> still contains the item that the [DataTransferItem](#)<sup>p877</sup> object represents, the [DataTransferItem](#)<sup>p877</sup> object's *mode* is the same as the [drag data store mode](#)<sup>p872</sup>. When the [DataTransferItem](#)<sup>p877</sup> object's [DataTransfer](#)<sup>p872</sup> object is *not* associated with a [drag data store](#)<sup>p871</sup>, or if the item that the [DataTransferItem](#)<sup>p877</sup> object represents has been removed from the relevant [drag data store item list](#)<sup>p871</sup>, the [DataTransferItem](#)<sup>p877</sup> object's *mode* is the *disabled mode*. The [drag data store](#)<sup>p871</sup> referenced in this section (which is used only when the [DataTransferItem](#)<sup>p877</sup> object is not in the *disabled mode*) is the [drag data store](#)<sup>p871</sup> with which the [DataTransferItem](#)<sup>p877</sup> object's [DataTransfer](#)<sup>p872</sup> object is associated.

The **kind** attribute must return the empty string if the [DataTransferItem](#)<sup>p877</sup> object is in the *disabled mode*; otherwise it must return the string given in the cell from the second column of the following table from the row whose cell in the first column contains [the drag data item kind](#)<sup>p871</sup> of the item represented by the [DataTransferItem](#)<sup>p877</sup> object:

Kind	String
Text	"string"
File	"file"

The **type** attribute must return the empty string if the [DataTransferItem](#)<sup>p877</sup> object is in the *disabled mode*; otherwise it must return [the drag data item type string](#)<sup>p872</sup> of the item represented by the [DataTransferItem](#)<sup>p877</sup> object.

The **[getAsString\(callback\)](#)** method must run the following steps:

1. If the *callback* is null, return.
2. If the [DataTransferItem](#)<sup>p877</sup> object is not in the [read/write mode](#)<sup>p872</sup> or the [read-only mode](#)<sup>p872</sup>, return. The callback is never invoked.
3. If [the drag data item kind](#)<sup>p871</sup> is not *text*, then return. The callback is never invoked.
4. Otherwise, [queue a task](#)<sup>p1125</sup> to invoke *callback*, passing the actual data of the item represented by the [DataTransferItem](#)<sup>p877</sup> object as the argument.

The **[getAsFile\(\)](#)** method must run the following steps:

1. If the [DataTransferItem](#)<sup>p877</sup> object is not in the [read/write mode](#)<sup>p872</sup> or the [read-only mode](#)<sup>p872</sup>, then return null.
2. If the [drag data item kind](#)<sup>p871</sup> is not *File*, then return null.
3. Return a new *File* object representing the actual data of the item represented by the [DataTransferItem](#)<sup>p877</sup> object.

### 6.11.4 The [DragEvent](#)<sup>p878</sup> interface §<sup>p87</sup><sub>8</sub>

The drag-and-drop processing model involves several events. They all use the [DragEvent](#)<sup>p878</sup> interface.

IDL

```
[Exposed=Window]
interface DragEvent : MouseEvent {
  constructor(DOMString type, optional DragEventInit eventInitDict = {});

  readonly attribute DataTransfer? dataTransfer;
};

dictionary DragEventInit : MouseEventInit {
  DataTransfer? dataTransfer = null;
};
```

For web developers (non-normative)

**[event.dataTransfer](#)<sup>p878</sup>**  
Returns the [DataTransfer](#)<sup>p872</sup> object for the event.

**Note**  
*Although, for consistency with other event interfaces, the [DragEvent](#)<sup>p878</sup> interface has a constructor, it is not particularly useful. In particular, there's no way to create a useful [DataTransfer](#)<sup>p872</sup> object from script, as [DataTransfer](#)<sup>p872</sup> objects have a processing and security model that is coordinated by the browser during drag-and-drops.*

The **[dataTransfer](#)** attribute of the [DragEvent](#)<sup>p878</sup> interface must return the value it was initialized to. It represents the context information for the event.

When a user agent is required to **fire a DND event** named *e* at an element, using a particular [drag data store](#)<sup>p871</sup>, and optionally with a specific *related target*, the user agent must run the following steps:

1. Let *dataDragStoreWasChanged* be false.
2. If no specific *related target* was provided, set *related target* to null.
3. Let *window* be the [relevant global object](#)<sup>p1083</sup> of the [Document](#)<sup>p139</sup> object of the specified target element.
4. If *e* is [dragstart](#)<sup>p884</sup>, then set the [drag data store mode](#)<sup>p872</sup> to the [read/write mode](#)<sup>p872</sup> and set *dataDragStoreWasChanged* to true.  
  
If *e* is [drop](#)<sup>p885</sup>, set the [drag data store mode](#)<sup>p872</sup> to the [read-only mode](#)<sup>p872</sup>.
5. Let *dataTransfer* be a newly created [DataTransfer](#)<sup>p872</sup> object associated with the given [drag data store](#)<sup>p871</sup>.
6. Set the [effectAllowed](#)<sup>p874</sup> attribute to the [drag data store](#)<sup>p871</sup>'s [drag data store allowed effects state](#)<sup>p872</sup>.
7. Set the [dropEffect](#)<sup>p874</sup> attribute to ["none"](#)<sup>p874</sup> if *e* is [dragstart](#)<sup>p884</sup>, [drag](#)<sup>p884</sup>, or [dragleave](#)<sup>p884</sup>; to the value corresponding to the [current drag operation](#)<sup>p882</sup> if *e* is [drop](#)<sup>p885</sup> or [dragend](#)<sup>p885</sup>; and to a value based on the [effectAllowed](#)<sup>p874</sup> attribute's value and the drag-and-drop source, as given by the following table, otherwise (i.e. if *e* is [dragenter](#)<sup>p884</sup> or [dragover](#)<sup>p884</sup>):

<a href="#">effectAllowed</a> <sup>p874</sup>	<a href="#">dropEffect</a> <sup>p874</sup>
<a href="#">"none"</a> <sup>p874</sup>	<a href="#">"none"</a> <sup>p874</sup>
<a href="#">"copy"</a> <sup>p874</sup>	<a href="#">"copy"</a> <sup>p874</sup>
<a href="#">"copyLink"</a> <sup>p874</sup>	<a href="#">"copy"</a> <sup>p874</sup> , or, if appropriate <sup>p879</sup> , <a href="#">"link"</a> <sup>p874</sup>
<a href="#">"copyMove"</a> <sup>p874</sup>	<a href="#">"copy"</a> <sup>p874</sup> , or, if appropriate <sup>p879</sup> , <a href="#">"move"</a> <sup>p874</sup>

<b>effectAllowed<sup>p874</sup></b>	<b>dropEffect<sup>p874</sup></b>
"all <sup>p874</sup> "	"copy <sup>p874</sup> ", or, if appropriate <sup>p879</sup> , either "link <sup>p874</sup> " or "move <sup>p874</sup> "
"link <sup>p874</sup> "	"link <sup>p874</sup> "
"linkMove <sup>p874</sup> "	"link <sup>p874</sup> ", or, if appropriate <sup>p879</sup> , "move <sup>p874</sup> "
"move <sup>p874</sup> "	"move <sup>p874</sup> "
"uninitialized <sup>p874</sup> " when what is being dragged is a selection from a text control	"move <sup>p874</sup> ", or, if appropriate <sup>p879</sup> , either "copy <sup>p874</sup> " or "link <sup>p874</sup> "
"uninitialized <sup>p874</sup> " when what is being dragged is a selection	"copy <sup>p874</sup> ", or, if appropriate <sup>p879</sup> , either "link <sup>p874</sup> " or "move <sup>p874</sup> "
"uninitialized <sup>p874</sup> " when what is being dragged is an a <sup>p257</sup> element with an href <sup>p383</sup> attribute	"link <sup>p874</sup> ", or, if appropriate <sup>p879</sup> , either "copy <sup>p874</sup> " or "move <sup>p874</sup> "
Any other case	"copy <sup>p874</sup> ", or, if appropriate <sup>p879</sup> , either "link <sup>p874</sup> " or "move <sup>p874</sup> "

Where the table above provides **possibly appropriate alternatives**, user agents may instead use the listed alternative values if platform conventions dictate that the user has requested those alternate effects.

#### Example

For example, Windows platform conventions are such that dragging while holding the "alt" key indicates a preference for linking the data, rather than moving or copying it. Therefore, on a Windows system, if "link<sup>p874</sup>" is an option according to the table above while the "alt" key is depressed, the user agent could select that instead of "copy<sup>p874</sup>" or "move<sup>p874</sup>".

- Let *event* be the result of [creating an event](#) using [DragEvent<sup>p878</sup>](#).
- Initialize *event*'s **type** attribute to *e*, its **bubbles** attribute to true, its **view** attribute to *window*, its **relatedTarget** attribute to *related target*, and its **dataTransfer<sup>p878</sup>** attribute to *dataTransfer*.
- If *e* is not [dragleave<sup>p884</sup>](#) or [dragend<sup>p885</sup>](#), then initialize *event*'s **cancelable** attribute to true.
- Initialize *event*'s mouse and key attributes initialized according to the state of the input devices as they would be for user interaction events.  
  
If there is no relevant pointing device, then initialize *event*'s **screenX**, **screenY**, **clientX**, **clientY**, and **button** attributes to 0.
- [Dispatch](#) *event* at the specified target element.
- Set the [drag data store allowed effects state<sup>p872</sup>](#) to the current value of *dataTransfer*'s **effectAllowed<sup>p874</sup>** attribute. (It can only have changed value if *e* is [dragstart<sup>p884</sup>](#).)
- If *dataDragStoreWasChanged* is true, then set the [drag data store mode<sup>p872</sup>](#) back to the [protected mode<sup>p872</sup>](#).
- Break the association between *dataTransfer* and the [drag data store<sup>p871</sup>](#).

### 6.11.5 Processing model <sup>p87</sup><sub>9</sub>

When the user attempts to begin a drag operation, the user agent must run the following steps. User agents must act as if these steps were run even if the drag actually started in another document or application and the user agent was not aware that the drag was occurring until it intersected with a document under the user agent's purview.

- Determine what is being dragged, as follows:

If the drag operation was invoked on a selection, then it is the selection that is being dragged.

Otherwise, if the drag operation was invoked on a [Document<sup>p139</sup>](#), it is the first element, going up the ancestor chain, starting at the node that the user tried to drag, that has the IDL attribute **draggable<sup>p885</sup>** set to true. If there is no such element, then nothing is being dragged; return, the drag-and-drop operation is never started.

Otherwise, the drag operation was invoked outside the user agent's purview. What is being dragged is defined by the document or application where the drag was started.

#### Note

[img](#)<sup>p346</sup> elements and [a](#)<sup>p257</sup> elements with an [href](#)<sup>p303</sup> attribute have their [draggable](#)<sup>p885</sup> attribute set to true by default.

2. [Create a drag data store](#)<sup>p872</sup>. All the DND events fired subsequently by the steps in this section must use this [drag data store](#)<sup>p871</sup>.
3. Establish which DOM node is the **source node**, as follows:

If it is a selection that is being dragged, then the [source node](#)<sup>p880</sup> is the [Text](#) node that the user started the drag on (typically the [Text](#) node that the user originally clicked). If the user did not specify a particular node, for example if the user just told the user agent to begin a drag of "the selection", then the [source node](#)<sup>p880</sup> is the first [Text](#) node containing a part of the selection.

Otherwise, if it is an element that is being dragged, then the [source node](#)<sup>p880</sup> is the element that is being dragged.

Otherwise, the [source node](#)<sup>p880</sup> is part of another document or application. When this specification requires that an event be dispatched at the [source node](#)<sup>p880</sup> in this case, the user agent must instead follow the platform-specific conventions relevant to that situation.

#### Note

Multiple events are fired on the [source node](#)<sup>p880</sup> during the course of the drag-and-drop operation.

4. Determine the **list of dragged nodes**, as follows:

If it is a selection that is being dragged, then the [list of dragged nodes](#)<sup>p880</sup> contains, in [tree order](#), every node that is partially or completely included in the selection (including all their ancestors).

Otherwise, the [list of dragged nodes](#)<sup>p880</sup> contains only the [source node](#)<sup>p880</sup>, if any.
5. If it is a selection that is being dragged, then add an item to the [drag data store item list](#)<sup>p871</sup>, with its properties set as follows:

#### [The drag data item type string](#)<sup>p872</sup>

"text/plain"

#### [The drag data item kind](#)<sup>p871</sup>

Text

#### The actual data

The text of the selection

Otherwise, if any files are being dragged, then add one item per file to the [drag data store item list](#)<sup>p871</sup>, with their properties set as follows:

#### [The drag data item type string](#)<sup>p872</sup>

The MIME type of the file, if known, or "application/octet-stream" otherwise.

#### [The drag data item kind](#)<sup>p871</sup>

File

#### The actual data

The file's contents and name.

#### Note

Dragging files can currently only happen from outside a [navigable](#)<sup>p989</sup>, for example from a file system manager application.

If the drag initiated outside of the application, the user agent must add items to the [drag data store item list](#)<sup>p871</sup> as appropriate for the data being dragged, honoring platform conventions where appropriate; however, if the platform conventions do not use [MIME types](#) to label dragged data, the user agent must make a best-effort attempt to map the types to MIME types, and, in any case, all the [drag data item type strings](#)<sup>p872</sup> must be [converted to ASCII lowercase](#).

User agents may also add one or more items representing the selection or dragged element(s) in other forms, e.g. as HTML.

6. If the [list of dragged nodes](#)<sup>p880</sup> is not empty, then [extract the microdata from those nodes into a JSON form](#)<sup>p821</sup>, and add one item to the [drag data store item list](#)<sup>p871</sup>, with its properties set as follows:

### [The drag data item type string](#)<sup>p872</sup>

[application/microdata+json](#)<sup>p1448</sup>

### [The drag data item kind](#)<sup>p871</sup>

Text

#### The actual data

The resulting JSON string.

#### 7. Run the following substeps:

1. Let *urls* be « ».

2. For each *node* in the [list of dragged nodes](#)<sup>p880</sup>:

##### If the node is an [a](#)<sup>p257</sup> element with an [href](#)<sup>p303</sup> attribute

Add to *urls* the result of [encoding-parsing-and-serializing a URL](#)<sup>p97</sup> given the element's [href](#)<sup>p303</sup> content attribute's value, relative to the element's [node document](#).

##### If the node is an [img](#)<sup>p346</sup> element with a [src](#)<sup>p347</sup> attribute

Add to *urls* the result of [encoding-parsing-and-serializing a URL](#)<sup>p97</sup> given the element's [src](#)<sup>p347</sup> content attribute's value, relative to the element's [node document](#).

3. If *urls* is still empty, then return.

4. Let *url string* be the result of concatenating the strings in *urls*, in the order they were added, separated by a U+000D CARRIAGE RETURN U+000A LINE FEED character pair (CRLF).

5. Add one item to the [drag data store item list](#)<sup>p871</sup>, with its properties set as follows:

### [The drag data item type string](#)<sup>p872</sup>

[text/uri-list](#)<sup>p1474</sup>

### [The drag data item kind](#)<sup>p871</sup>

Text

#### The actual data

*url string*

8. Update the [drag data store default feedback](#)<sup>p872</sup> as appropriate for the user agent (if the user is dragging the selection, then the selection would likely be the basis for this feedback; if the user is dragging an element, then that element's rendering would be used; if the drag began outside the user agent, then the platform conventions for determining the drag feedback should be used).

9. [Fire a DND event](#)<sup>p878</sup> named [dragstart](#)<sup>p884</sup> at the [source node](#)<sup>p880</sup>.

If the event is canceled, then the drag-and-drop operation should not occur; return.

#### Note

*Since events with no event listeners registered are, almost by definition, never canceled, drag-and-drop is always available to the user if the author does not specifically prevent it.*

10. [Fire a pointer event](#) at the [source node](#)<sup>p880</sup> named [pointercancel](#), and fire any other follow-up events as required by *Pointer Events*. [\[POINTEREVENTS\]](#)<sup>p1481</sup>

11. [Initiate the drag-and-drop operation](#)<sup>p881</sup> in a manner consistent with platform conventions, and as described below.

The drag-and-drop feedback must be generated from the first of the following sources that is available:

1. The [drag data store bitmap](#)<sup>p872</sup>, if any. In this case, the [drag data store hot spot coordinate](#)<sup>p872</sup> should be used as hints for where to put the cursor relative to the resulting image. The values are expressed as distances in [CSS pixels](#) from the left side and from the top side of the image respectively. [\[CSS\]](#)<sup>p1476</sup>
2. The [drag data store default feedback](#)<sup>p872</sup>.

From the moment that the user agent is to **initiate the drag-and-drop operation**, until the end of the drag-and-drop operation, device input events (e.g. mouse and keyboard events) must be suppressed.

During the drag operation, the element directly indicated by the user as the drop target is called the **immediate user selection**. (Only elements can be selected by the user; other nodes must not be made available as drop targets.) However, the [immediate user selection](#)<sup>p882</sup> is not necessarily the **current target element**, which is the element currently selected for the drop part of the drag-and-drop operation.

The [immediate user selection](#)<sup>p882</sup> changes as the user selects different elements (either by pointing at them with a pointing device, or by selecting them in some other way). The [current target element](#)<sup>p882</sup> changes when the [immediate user selection](#)<sup>p882</sup> changes, based on the results of event listeners in the document, as described below.

Both the [current target element](#)<sup>p882</sup> and the [immediate user selection](#)<sup>p882</sup> can be null, which means no target element is selected. They can also both be elements in other (DOM-based) documents, or other (non-web) programs altogether. (For example, a user could drag text to a word-processor.) The [current target element](#)<sup>p882</sup> is initially null.

In addition, there is also a **current drag operation**, which can take on the values "**none**", "**copy**", "**link**", and "**move**". Initially, it has the value "[none](#)<sup>p882</sup>". It is updated by the user agent as described in the steps below.

User agents must, as soon as the drag operation is [initiated](#)<sup>p881</sup> and every 350ms ( $\pm 200$ ms) thereafter for as long as the drag operation is ongoing, [queue a task](#)<sup>p1125</sup> to perform the following steps in sequence:

1. If the user agent is still performing the previous iteration of the sequence (if any) when the next iteration becomes due, return for this iteration (effectively "skipping missed frames" of the drag-and-drop operation).
2. [Fire a DND event](#)<sup>p878</sup> named [drag](#)<sup>p884</sup> at the [source node](#)<sup>p880</sup>. If this event is canceled, the user agent must set the [current drag operation](#)<sup>p882</sup> to "[none](#)<sup>p882</sup>" (no drag operation).
3. If the [drag](#)<sup>p884</sup> event was not canceled and the user has not ended the drag-and-drop operation, check the state of the drag-and-drop operation, as follows:

1. If the user is indicating a different [immediate user selection](#)<sup>p882</sup> than during the last iteration (or if this is the first iteration), and if this [immediate user selection](#)<sup>p882</sup> is not the same as the [current target element](#)<sup>p882</sup>, then update the [current target element](#)<sup>p882</sup> as follows:

↪ If the new [immediate user selection](#)<sup>p882</sup> is null

Set the [current target element](#)<sup>p882</sup> to null also.

↪ If the new [immediate user selection](#)<sup>p882</sup> is in a non-DOM document or application

Set the [current target element](#)<sup>p882</sup> to the [immediate user selection](#)<sup>p882</sup>.

↪ Otherwise

[Fire a DND event](#)<sup>p878</sup> named [dragenter](#)<sup>p884</sup> at the [immediate user selection](#)<sup>p882</sup>.

If the event is canceled, then set the [current target element](#)<sup>p882</sup> to the [immediate user selection](#)<sup>p882</sup>.

Otherwise, run the appropriate step from the following list:

↪ If the [immediate user selection](#)<sup>p882</sup> is a text control (e.g., [textarea](#)<sup>p579</sup>, or an [input](#)<sup>p520</sup> element whose [type](#)<sup>p523</sup> attribute is in the [Text](#)<sup>p527</sup> state) or an [editing host](#)<sup>p855</sup> or [editable](#) element, and the [drag data store item list](#)<sup>p871</sup> has an item with the [drag data item type string](#)<sup>p872</sup> "[text/plain](#)" and the [drag data item kind](#)<sup>p871</sup> [text](#)

Set the [current target element](#)<sup>p882</sup> to the [immediate user selection](#)<sup>p882</sup> anyway.

↪ If the [immediate user selection](#)<sup>p882</sup> is the [body element](#)<sup>p136</sup>

Leave the [current target element](#)<sup>p882</sup> unchanged.

↪ Otherwise

[Fire a DND event](#)<sup>p878</sup> named [dragenter](#)<sup>p884</sup> at the [body element](#)<sup>p136</sup>, if there is one, or at the [Document](#)<sup>p130</sup> object, if not. Then, set the [current target element](#)<sup>p882</sup> to the [body element](#)<sup>p136</sup>, regardless of whether that event was canceled or not.

2. If the previous step caused the [current target element](#)<sup>p882</sup> to change, and if the previous target element was not null or a part of a non-DOM document, then [fire a DND event](#)<sup>p878</sup> named [dragleave](#)<sup>p884</sup> at the previous target element, with the new [current target element](#)<sup>p882</sup> as the specific *related target*.
3. If the [current target element](#)<sup>p882</sup> is a DOM element, then [fire a DND event](#)<sup>p878</sup> named [dragover](#)<sup>p884</sup> at this [current target element](#)<sup>p882</sup>.

If the [dragover](#)<sup>p884</sup> event is not canceled, run the appropriate step from the following list:

↪ If the [current target element](#)<sup>p882</sup> is a text control (e.g., [textarea](#)<sup>p579</sup>, or an [input](#)<sup>p520</sup> element whose [type](#)<sup>p523</sup> attribute is in the [Text](#)<sup>p527</sup> state) or an [editing host](#)<sup>p855</sup> or [editable](#) element, and the [drag data store item list](#)<sup>p871</sup> has an item with the [drag data item type string](#)<sup>p872</sup> "[text/plain](#)" and the [drag data item kind](#)<sup>p871</sup> [text](#)

Set the [current drag operation](#)<sup>p882</sup> to either "[copy](#)<sup>p882</sup>" or "[move](#)<sup>p882</sup>", as appropriate given the platform conventions.

↪ Otherwise

Reset the [current drag operation](#)<sup>p882</sup> to "[none](#)<sup>p882</sup>".

Otherwise (if the [dragover](#)<sup>p884</sup> event is canceled), set the [current drag operation](#)<sup>p882</sup> based on the values of the [effectAllowed](#)<sup>p874</sup> and [dropEffect](#)<sup>p874</sup> attributes of the [DragEvent](#)<sup>p878</sup> object's [dataTransfer](#)<sup>p878</sup> object as they stood after the event [dispatch](#) finished, as per the following table:

<a href="#">effectAllowed</a> <sup>p874</sup>	<a href="#">dropEffect</a> <sup>p874</sup>	Drag operation
" <a href="#">uninitialized</a> <sup>p874</sup> ", " <a href="#">copy</a> <sup>p874</sup> ", " <a href="#">copyLink</a> <sup>p874</sup> ", " <a href="#">copyMove</a> <sup>p874</sup> ", or " <a href="#">all</a> <sup>p874</sup> "	" <a href="#">copy</a> <sup>p874</sup> "	" <a href="#">copy</a> <sup>p882</sup> "
" <a href="#">uninitialized</a> <sup>p874</sup> ", " <a href="#">link</a> <sup>p874</sup> ", " <a href="#">copyLink</a> <sup>p874</sup> ", " <a href="#">linkMove</a> <sup>p874</sup> ", or " <a href="#">all</a> <sup>p874</sup> "	" <a href="#">link</a> <sup>p874</sup> "	" <a href="#">link</a> <sup>p882</sup> "
" <a href="#">uninitialized</a> <sup>p874</sup> ", " <a href="#">move</a> <sup>p874</sup> ", " <a href="#">copyMove</a> <sup>p874</sup> ", " <a href="#">linkMove</a> <sup>p874</sup> ", or " <a href="#">all</a> <sup>p874</sup> "	" <a href="#">move</a> <sup>p874</sup> "	" <a href="#">move</a> <sup>p882</sup> "
Any other case		" <a href="#">none</a> <sup>p882</sup> "

- Otherwise, if the [current target element](#)<sup>p882</sup> is not a DOM element, use platform-specific mechanisms to determine what drag operation is being performed (none, copy, link, or move), and set the [current drag operation](#)<sup>p882</sup> accordingly.
- Update the drag feedback (e.g. the mouse cursor) to match the [current drag operation](#)<sup>p882</sup>, as follows:

Drag operation	Feedback
" <a href="#">copy</a> <sup>p882</sup> "	Data will be copied if dropped here.
" <a href="#">link</a> <sup>p882</sup> "	Data will be linked if dropped here.
" <a href="#">move</a> <sup>p882</sup> "	Data will be moved if dropped here.
" <a href="#">none</a> <sup>p882</sup> "	No operation allowed, dropping here will cancel the drag-and-drop operation.

- Otherwise, if the user ended the drag-and-drop operation (e.g. by releasing the mouse button in a mouse-driven drag-and-drop interface), or if the [drag](#)<sup>p884</sup> event was canceled, then this will be the last iteration. Run the following steps, then stop the drag-and-drop operation:
  - If the [current drag operation](#)<sup>p882</sup> is "[none](#)<sup>p882</sup>" (no drag operation), or, if the user ended the drag-and-drop operation by canceling it (e.g. by hitting the Escape key), or if the [current target element](#)<sup>p882</sup> is null, then the drag operation failed. Run these substeps:
    - Let *dropped* be false.
    - If the [current target element](#)<sup>p882</sup> is a DOM element, [fire a DND event](#)<sup>p878</sup> named [dragleave](#)<sup>p884</sup> at it; otherwise, if it is not null, use platform-specific conventions for drag cancellation.
    - Set the [current drag operation](#)<sup>p882</sup> to "[none](#)<sup>p882</sup>".

Otherwise, the drag operation might be a success; run these substeps:

- Let *dropped* be true.
- If the [current target element](#)<sup>p882</sup> is a DOM element, [fire a DND event](#)<sup>p878</sup> named [drop](#)<sup>p885</sup> at it; otherwise, use platform-specific conventions for indicating a drop.
- If the event is canceled, set the [current drag operation](#)<sup>p882</sup> to the value of the [dropEffect](#)<sup>p874</sup> attribute of the [DragEvent](#)<sup>p878</sup> object's [dataTransfer](#)<sup>p878</sup> object as it stood after the event [dispatch](#) finished.

Otherwise, the event is not canceled; perform the event's default action, which depends on the exact target as follows:

↪ If the [current target element](#)<sup>p882</sup> is a text control (e.g., [textarea](#)<sup>p579</sup>, or an [input](#)<sup>p520</sup> element whose [type](#)<sup>p523</sup> attribute is in the [Text](#)<sup>p527</sup> state) or an [editing host](#)<sup>p855</sup> or [editable](#) element, and the [drag data store item list](#)<sup>p871</sup> has an item with the [drag data item type](#)

### **string<sup>p872</sup> "text/plain" and the drag data item kind<sup>p871</sup> text**

Insert the actual data of the first item in the [drag data store item list<sup>p871</sup>](#) to have a [drag data item type string<sup>p872</sup>](#) of "text/plain" and a [drag data item kind<sup>p871</sup>](#) that is text into the text control or [editing host<sup>p855</sup>](#) or [editable](#) element in a manner consistent with platform-specific conventions (e.g. inserting it at the current mouse cursor position, or inserting it at the end of the field).

#### ↪ Otherwise

Reset the [current drag operation<sup>p882</sup>](#) to "none<sup>p882</sup>".

2. [Fire a DND event<sup>p878</sup>](#) named [dragend<sup>p885</sup>](#) at the [source node<sup>p880</sup>](#).
3. Run the appropriate steps from the following list as the default action of the [dragend<sup>p885</sup>](#) event:
  - ↪ If *dropped* is true, the [current target element<sup>p882</sup>](#) is a *text control* (see below), the [current drag operation<sup>p882</sup>](#) is "move<sup>p882</sup>", and the source of the drag-and-drop operation is a selection in the DOM that is entirely contained within an [editing host<sup>p855</sup>](#)  
[Delete the selection.](#)
  - ↪ If *dropped* is true, the [current target element<sup>p882</sup>](#) is a *text control* (see below), the [current drag operation<sup>p882</sup>](#) is "move<sup>p882</sup>", and the source of the drag-and-drop operation is a selection in a text control  
The user agent should delete the dragged selection from the relevant text control.
  - ↪ If *dropped* is false or if the [current drag operation<sup>p882</sup>](#) is "none<sup>p882</sup>"  
The drag was canceled. If the platform conventions dictate that this be represented to the user (e.g. by animating the dragged selection going back to the source of the drag-and-drop operation), then do so.
  - ↪ Otherwise  
The event has no default action.

For the purposes of this step, a *text control* is a [textarea<sup>p579</sup>](#) element or an [input<sup>p520</sup>](#) element whose [type<sup>p523</sup>](#) attribute is in one of the [Text<sup>p527</sup>](#), [Search<sup>p527</sup>](#), [Tel<sup>p528</sup>](#), [URI<sup>p529</sup>](#), [Email<sup>p530</sup>](#), [Password<sup>p531</sup>](#), or [Number<sup>p537</sup>](#) states.

#### Note

User agents are encouraged to consider how to react to drags near the edge of scrollable regions. For example, if a user drags a link to the bottom of the [viewport](#) on a long page, it might make sense to scroll the page so that the user can drop the link lower on the page.

#### Note

This model is independent of which [Document<sup>p130</sup>](#) object the nodes involved are from; the events are fired as described above and the rest of the processing model runs as described above, irrespective of how many documents are involved in the operation.

## 6.11.6 Events summary <sup>p88</sup><sub>4</sub>

This section is non-normative.

The following events are involved in the drag-and-drop model.

Event name	Target	Cancelable?	Drag data store mode <sup>p872</sup>	dropEffect <sup>p874</sup>	Default Action
dragstart	<a href="#">Source node<sup>p880</sup></a>	✓ Cancelable	<a href="#">Read/write mode<sup>p872</sup></a>	"none <sup>p874</sup> "	Initiate the drag-and-drop operation
drag	<a href="#">Source node<sup>p880</sup></a>	✓ Cancelable	<a href="#">Protected mode<sup>p872</sup></a>	"none <sup>p874</sup> "	Continue the drag-and-drop operation
dragenter	<a href="#">Immediate user selection<sup>p882</sup></a> or <a href="#">the body element<sup>p136</sup></a>	✓ Cancelable	<a href="#">Protected mode<sup>p872</sup></a>	<a href="#">Based on effectAllowed value<sup>p878</sup></a>	Reject <a href="#">immediate user selection<sup>p882</sup></a> as potential <a href="#">target element<sup>p882</sup></a>
dragleave	<a href="#">Previous target element<sup>p882</sup></a>	—	<a href="#">Protected mode<sup>p872</sup></a>	"none <sup>p874</sup> "	None
dragover	<a href="#">Current target element<sup>p882</sup></a>	✓ Cancelable	<a href="#">Protected mode<sup>p872</sup></a>	<a href="#">Based on effectAllowed value<sup>p878</sup></a>	Reset the <a href="#">current drag operation<sup>p882</sup></a> to "none"

Event name	Target	Cancelable?	Drag data store mode <sup>p872</sup>	dropEffect <sup>p874</sup>	Default Action
drop	Current target element <sup>p882</sup>	✓ Cancelable	Read-only mode <sup>p872</sup>	Current drag operation <sup>p882</sup>	Varies
dragend	Source node <sup>p880</sup>	—	Protected mode <sup>p872</sup>	Current drag operation <sup>p882</sup>	Varies

All of these events bubble, are composed, and the [effectAllowed](#)<sup>p874</sup> attribute always has the value it had after the [dragstart](#)<sup>p884</sup> event, defaulting to "[uninitialized](#)<sup>p874</sup>" in the [dragstart](#)<sup>p884</sup> event.

### 6.11.7 The [draggable](#)<sup>p885</sup> attribute §<sup>p888</sup><sub>5</sub>

All [HTML elements](#)<sup>p45</sup> may have the [draggable](#) content attribute set. The [draggable](#)<sup>p885</sup> attribute is an [enumerated attribute](#)<sup>p76</sup> with the following keywords and states:

Keyword	State	Brief description
true	true	The element will be draggable.
false	false	The element will not be draggable.

The attribute's [missing value default](#)<sup>p76</sup> and [invalid value default](#)<sup>p76</sup> are both the **auto** state. The auto state uses the default behavior of the user agent.

An element with a [draggable](#)<sup>p885</sup> attribute should also have a [title](#)<sup>p157</sup> attribute that names the element for the purpose of non-visual interactions.

For web developers (non-normative)

[element.draggable](#)<sup>p885</sup> [ = value ]

Returns true if the element is draggable; otherwise, returns false.

Can be set, to override the default and set the [draggable](#)<sup>p885</sup> content attribute.

The [draggable](#) IDL attribute, whose value depends on the content attribute's in the way described below, controls whether or not the element is draggable. Generally, only text selections are draggable, but elements whose [draggable](#)<sup>p885</sup> IDL attribute is true become draggable as well.

If an element's [draggable](#)<sup>p885</sup> content attribute has the state [true](#)<sup>p885</sup>, the [draggable](#)<sup>p885</sup> IDL attribute must return true.

Otherwise, if the element's [draggable](#)<sup>p885</sup> content attribute has the state [false](#)<sup>p885</sup>, the [draggable](#)<sup>p885</sup> IDL attribute must return false.

Otherwise, the element's [draggable](#)<sup>p885</sup> content attribute has the state [auto](#)<sup>p885</sup>. If the element is an [img](#)<sup>p346</sup> element, an [object](#)<sup>p402</sup> element that [represents](#)<sup>p141</sup> an image, or an [a](#)<sup>p257</sup> element with an [href](#)<sup>p303</sup> content attribute, the [draggable](#)<sup>p885</sup> IDL attribute must return true; otherwise, the [draggable](#)<sup>p885</sup> IDL attribute must return false.

If the [draggable](#)<sup>p885</sup> IDL attribute is set to the value false, the [draggable](#)<sup>p885</sup> content attribute must be set to the literal value "false".

If the [draggable](#)<sup>p885</sup> IDL attribute is set to the value true, the [draggable](#)<sup>p885</sup> content attribute must be set to the literal value "true".

### 6.11.8 Security risks in the drag-and-drop model §<sup>p888</sup><sub>5</sub>

User agents must not make the data added to the [DataTransfer](#)<sup>p872</sup> object during the [dragstart](#)<sup>p884</sup> event available to scripts until the [drop](#)<sup>p885</sup> event, because otherwise, if a user were to drag sensitive information from one document to a second document, crossing a hostile third document in the process, the hostile document could intercept the data.

For the same reason, user agents must consider a drop to be successful only if the user specifically ended the drag operation — if any scripts end the drag operation, it must be considered unsuccessful (canceled) and the [drop](#)<sup>p885</sup> event must not be fired.

User agents should take care to not start drag-and-drop operations in response to script actions. For example, in a mouse-and-window environment, if a script moves a window while the user has their mouse button depressed, the UA would not consider that to start a drag. This is important because otherwise UAs could cause data to be dragged from sensitive sources and dropped into hostile documents without the user's consent.

User agents should filter potentially active (scripted) content (e.g. HTML) when it is dragged and when it is dropped, using a safelist of known-safe features. Similarly, [relative URLs](#) should be turned into absolute URLs to avoid references changing in unexpected ways. This specification does not specify how this is performed.

#### Example

Consider a hostile page providing some content and getting the user to select and drag and drop (or indeed, copy and paste) that content to a victim page's [contenteditable](#)<sup>p853</sup> region. If the browser does not ensure that only safe content is dragged, potentially unsafe content such as scripts and event handlers in the selection, once dropped (or pasted) into the victim site, get the privileges of the victim site. This would thus enable a cross-site scripting attack.

## 6.12 The [popover](#)<sup>p886</sup> attribute §<sup>p886</sup><sub>6</sub>

All [HTML elements](#)<sup>p45</sup> may have the [popover](#) content attribute set. When specified, the element won't be rendered until it becomes shown, at which point it will be rendered on top of other page content.

#### Example

The [popover](#)<sup>p886</sup> attribute is a global attribute that allows authors flexibility to ensure popover functionality can be applied to elements with the most relevant semantics.

The following demonstrates how one might create a popover sub-navigation list of links, within the global navigation for a website.

```
<ul>
  <li>
    <a href=...>All Products</a>
    <button popovertarget=sub-nav>
      <img src=down-arrow.png alt="Product pages">
    </button>
    <ul popover id=sub-nav>
      <li><a href=...>Shirts</a>
      <li><a href=...>Shoes</a>
      <li><a href=...>Hats etc.</a>
    </ul>
  </li>
  <!-- other list items and links here -->
</ul>
```

When using [popover](#)<sup>p886</sup> on elements without accessibility semantics, for instance the [div](#)<sup>p256</sup> element, authors should use the appropriate ARIA attributes to ensure the popover is accessible.

#### Example

The following shows the baseline markup to create a custom menu popover, where the first menuitem will receive keyboard focus when the popover is invoked due to the use of the `autofocus` attribute. Navigating the menuitems with arrow keys and activation behaviors would still need author scripting. Additional requirements for building custom menus widgets are defined in the [WAI-ARIA specification](#).

```
<button popovertarget=m>Actions</button>
<div role=menu id=m popover>
  <button role=menuitem tabindex=-1 autofocus>Edit</button>
  <button role=menuitem tabindex=-1>Hide</button>
  <button role=menuitem tabindex=-1>Delete</button>
</div>
```

A popover can be useful for rendering a status message, confirming the action performed by the user. The following demonstrates how one could reveal a popover in an [output](#)<sup>p584</sup> element.

```
<button id=submit>Submit</button>
```

```

<p><output><span popover=manual></span></output></p>

<script>
  const sBtn = document.getElementById("submit");
  const outSpan = document.querySelector("output [popover=manual]");
  let successMessage;
  let errorMessage;

  /* define logic for determining success of action
  and determining the appropriate success or error
  messages to use */

  sBtn.addEventListener("click", ()=> {
    if ( success ) {
      outSpan.textContent = successMessage;
    }
    else {
      outSpan.textContent = errorMessage;
    }
    outSpan.showPopover();

    setTimeout(function () {
      outSpan.hidePopover();
    }, 10000);
  });
</script>

```

## Note

Inserting a popover element into an [output](#)<sup>p584</sup> element will generally cause screen readers to announce the content when it becomes visible. Depending on the complexity or frequency of the content, this could be either useful or annoying to users of these assistive technologies. Keep this in mind when using the [output](#)<sup>p584</sup> element or other ARIA live regions to ensure the best user experience.

The [popover](#)<sup>p886</sup> attribute is an [enumerated attribute](#)<sup>p76</sup> with the following keywords and states:

Keyword	State	Brief description
<b>auto</b> (the empty string)	<b>auto</b>	Closes other popovers when opened; has <a href="#">light dismiss</a> <sup>p896</sup> and responds to <a href="#">close requests</a> <sup>p863</sup> .
<b>manual</b>	<b>manual</b>	Does not close other popovers; does not <a href="#">light dismiss</a> <sup>p896</sup> or respond to <a href="#">close requests</a> <sup>p863</sup> .

The attribute's [missing value default](#)<sup>p76</sup> is the **no popover** state, and its [invalid value default](#)<sup>p76</sup> is the [manual](#)<sup>p887</sup> state.

The **popover** IDL attribute must [reflect](#)<sup>p104</sup> the [popover](#)<sup>p886</sup> attribute, [limited to only known values](#)<sup>p105</sup>.

Every [HTML element](#)<sup>p45</sup> has a **popover visibility state**, initially [hidden](#)<sup>p887</sup>, with these potential values:

- hidden**
- showing**

The [Document](#)<sup>p130</sup> has a **popover pointerdown target**, which is an [HTML element](#)<sup>p45</sup> or null, initially null.

Every [HTML element](#)<sup>p45</sup> has a **popover invoker**, which is an [HTML element](#)<sup>p45</sup> or null, initially set to null.

Every [HTML element](#)<sup>p45</sup> has a **popover showing or hiding**, which is a boolean, initially set to false.

Every [HTML element](#)<sup>p45</sup> **popover toggle task tracker**, which is a [toggle task tracker](#)<sup>p833</sup> or null, initially null.

Every [HTML element](#)<sup>p45</sup> has a **popover close watcher**, which is a [close watcher](#)<sup>p865</sup> or null, initially null.

The following [attribute change steps](#), given *element*, *localName*, *oldValue*, *value*, and *namespace*, are used for all [HTML elements](#)<sup>p45</sup>:

1. If *namespace* is not null, then return.
2. If *localName* is not [popover<sup>p886</sup>](#), then return.
3. If *element*'s [popover visibility state<sup>p887</sup>](#) is in the [showing state<sup>p887</sup>](#) and *oldValue* and *value* are in different [states<sup>p886</sup>](#), then run the [hide popover algorithm<sup>p890</sup>](#) given *element*, true, true, and false.

#### For web developers (non-normative)

##### **`element.showPopoverp888()`**

Shows the popover *element* by adding it to the top layer. If *element*'s [popover<sup>p886</sup>](#) attribute is in the [auto<sup>p887</sup>](#) state, then this will also close all other [auto<sup>p887</sup>](#) popovers unless they are an ancestor of *element* according to the [topmost popover ancestor<sup>p892</sup>](#) algorithm.

##### **`element.hidePopoverp889()`**

Hides the popover *element* by removing it from the top layer and applying `display: none` to it.

##### **`element.togglePopoverp891()`**

If the popover *element* is not showing, then this method shows it. Otherwise, this method hides it. This method returns true if the popover is open after calling it, otherwise false.

The **`showPopover(options)`** method steps are:

1. Let *invoker* be *options*["[source<sup>p142</sup>](#)"] if it [exists](#); otherwise, null.
2. Run [show popover<sup>p888</sup>](#) given [this](#), true, and *invoker*.

To **show popover**, given an [HTML element<sup>p45</sup>](#) *element*, a boolean *throwExceptions*, and an [HTML element<sup>p45</sup>](#) or null *invoker*:

1. If the result of running [check popover validity<sup>p893</sup>](#) given *element*, false, *throwExceptions*, and null is false, then return.
2. Let *document* be *element*'s [node document](#).
3. **Assert:** *element*'s [popover invoker<sup>p887</sup>](#) is null.
4. **Assert:** *element* is not in *document*'s [top layer](#).
5. Let *nestedShow* be *element*'s [popover showing or hiding<sup>p887</sup>](#).
6. Set *element*'s [popover showing or hiding<sup>p887</sup>](#) to true.
7. Let *cleanupShowingFlag* be the following steps:
  1. If *nestedShow* is false, then set *element*'s [popover showing or hiding<sup>p887</sup>](#) to false.
8. If the result of [firing an event](#) named [beforetoggle<sup>p1471</sup>](#), using [ToggleEvent<sup>p833</sup>](#), with the [cancelable](#) attribute initialized to true, the [oldState<sup>p833</sup>](#) attribute initialized to "closed", and the [newState<sup>p833</sup>](#) attribute initialized to "open" at *element* is false, then run *cleanupShowingFlag* and return.
9. If the result of running [check popover validity<sup>p893</sup>](#) given *element*, false, *throwExceptions*, and *document* is false, then run *cleanupShowingFlag* and return.

#### Note

[Check popover validity<sup>p893</sup>](#) is called again because firing the [beforetoggle<sup>p1471</sup>](#) event could have disconnected this *element* or changed its [popover<sup>p886</sup>](#) attribute.

10. Let *shouldRestoreFocus* be false.
11. If *element*'s [popover<sup>p886</sup>](#) attribute is in the [auto<sup>p887</sup>](#) state, then:
  1. Let *originalType* be the value of *element*'s [popover<sup>p886</sup>](#) attribute.
  2. Let *ancestor* be the result of running the [topmost popover ancestor<sup>p892</sup>](#) algorithm given *element*, *invoker*, and true.
  3. If *ancestor* is null, then set *ancestor* to *document*.
  4. Run [hide all popovers until<sup>p891</sup>](#) given *ancestor*, false, and not *nestedShow*.
  5. If *originalType* is not equal to the value of *element*'s [popover<sup>p886</sup>](#) attribute, then:

1. If `throwExceptions` is true, then throw a `"InvalidStateError" DOMException`.
2. Return.
6. If the result of running `check popover validity`<sup>p893</sup> given `element`, false, `throwExceptions`, and `document` is false, then run `cleanupShowingFlag` and return.

**Note**

*`Check popover validity`<sup>p893</sup> is called again because running `hide all popovers until`<sup>p891</sup> above could have fired the `beforetoggle`<sup>p1471</sup> event, and an event handler could have disconnected this element or changed its `popover`<sup>p886</sup> attribute.*

7. If the result of running `topmost auto popover`<sup>p893</sup> on `document` is null, then set `shouldRestoreFocus` to true.

**Note**

*This ensures that focus is returned to the previously-focused element only for the first popover in a stack.*

8. Set `element`'s `popover close watcher`<sup>p887</sup> to the result of `establishing a close watcher`<sup>p865</sup> given `element`'s `relevant global object`<sup>p1083</sup>, with:
  - `cancelAction`<sup>p865</sup> being to return true.
  - `closeAction`<sup>p865</sup> being to `hide a popover`<sup>p890</sup> given `element`, true, true, and false.
12. Set `element`'s `previously focused element`<sup>p652</sup> to null.
13. Let `originallyFocusedElement` be `document`'s `focused area of the document`<sup>p836</sup>'s `DOM anchor`<sup>p835</sup>.
14. `Add an element to the top layer` given `element`.
15. Set `element`'s `popover visibility state`<sup>p887</sup> to `showing`<sup>p887</sup>.
16. Set `element`'s `popover invoker`<sup>p887</sup> to `invoker`.
17. Set `element`'s `implicit anchor element` to `invoker`.
18. Run the `popover focusing steps`<sup>p893</sup> given `element`.
19. If `shouldRestoreFocus` is true and `element`'s `popover`<sup>p886</sup> attribute is not in the `no popover`<sup>p887</sup> state, then set `element`'s `previously focused element`<sup>p652</sup> to `originallyFocusedElement`.
20. `Queue a popover toggle event task`<sup>p889</sup> given `element`, "closed", and "open".
21. Run `cleanupShowingFlag`.

To **queue a popover toggle event task** given an element `element`, a string `oldState`, and a string `newState`:

1. If `element`'s `popover toggle task tracker`<sup>p887</sup> is not null, then:
  1. Set `oldState` to `element`'s `popover toggle task tracker`<sup>p887</sup>'s `old state`<sup>p833</sup>.
  2. Remove `element`'s `popover toggle task tracker`<sup>p887</sup>'s `task`<sup>p833</sup> from its `task queue`<sup>p1123</sup>.
  3. Set `element`'s `popover toggle task tracker`<sup>p887</sup> to null.
2. `Queue an element task`<sup>p1125</sup> given the `DOM manipulation task source`<sup>p1134</sup> and `element` to run the following steps:
  1. `Fire an event` named `toggle`<sup>p1472</sup> at `element`, using `ToggleEvent`<sup>p833</sup>, with the `oldState`<sup>p833</sup> attribute initialized to `oldState` and the `newState`<sup>p833</sup> attribute initialized to `newState`.
  2. Set `element`'s `popover toggle task tracker`<sup>p887</sup> to null.
3. Set `element`'s `popover toggle task tracker`<sup>p887</sup> to a struct with `task`<sup>p833</sup> set to the just-queued `task`<sup>p1124</sup> and `old state`<sup>p833</sup> set to `oldState`.

The `hidePopover()` method steps are:

1. Run the `hide popover algorithm`<sup>p890</sup> given `this`, true, true, and true.

To **hide a popover** given an [HTML element](#)<sup>p45</sup> *element*, a boolean *focusPreviousElement*, a boolean *fireEvents*, and a boolean *throwExceptions*:

1. If the result of running [check popover validity](#)<sup>p893</sup> given *element*, *true*, *throwExceptions*, and *null* is *false*, then return.
2. Let *document* be *element*'s [node document](#).
3. Let *nestedHide* be *element*'s [popover showing or hiding](#)<sup>p887</sup>.
4. Set *element*'s [popover showing or hiding](#)<sup>p887</sup> to *true*.
5. If *nestedHide* is *true*, then set *fireEvents* to *false*.
6. Let *cleanupSteps* be the following steps:
  1. If *nestedHide* is *false*, then set *element*'s [popover showing or hiding](#)<sup>p887</sup> to *false*.
  2. If *element*'s [popover close watcher](#)<sup>p887</sup> is not *null*, then:
    1. [Destroy](#)<sup>p866</sup> *element*'s [popover close watcher](#)<sup>p887</sup>.
    2. Set *element*'s [popover close watcher](#)<sup>p887</sup> to *null*.
7. If *element*'s [popover](#)<sup>p886</sup> attribute is in the [auto](#)<sup>p887</sup> state, then:
  1. Run [hide all popovers until](#)<sup>p891</sup> given *element*, *focusPreviousElement*, and *fireEvents*.
  2. If the result of running [check popover validity](#)<sup>p893</sup> given *element*, *true*, and *throwExceptions* is *false*, then run *cleanupSteps* and return.

**Note**

*Check popover validity*<sup>p893</sup> is called again because running [hide all popovers until](#)<sup>p891</sup> could have disconnected element or changed its [popover](#)<sup>p886</sup> attribute.

8. Let *autoPopoverListContainsElement* be *true* if *document*'s [showing auto popover list](#)<sup>p894</sup>'s last item is *element*, otherwise *false*.
9. Set *element*'s [popover invoker](#)<sup>p887</sup> to *null*.
10. If *fireEvents* is *true*:
  1. [Fire an event](#) named [beforetoggle](#)<sup>p1471</sup>, using [ToggleEvent](#)<sup>p833</sup>, with the [oldState](#)<sup>p833</sup> attribute initialized to "open" and the [newState](#)<sup>p833</sup> attribute initialized to "closed" at *element*.
  2. If *autoPopoverListContainsElement* is *true* and *document*'s [showing auto popover list](#)<sup>p894</sup>'s last item is not *element*, then run [hide all popovers until](#)<sup>p891</sup> given *element*, *focusPreviousElement*, and *false*.
  3. If the result of running [check popover validity](#)<sup>p893</sup> given *element*, *true*, *throwExceptions*, and *null* is *false*, then run *cleanupSteps* and return.

**Note**

*Check popover validity*<sup>p893</sup> is called again because firing the [beforetoggle](#)<sup>p1471</sup> event could have disconnected element or changed its [popover](#)<sup>p886</sup> attribute.

4. [Request an element to be removed from the top layer](#) given *element*.
5. Set *element*'s [implicit anchor element](#) to *null*.
11. Otherwise, [remove an element from the top layer immediately](#) given *element*.
12. Set *element*'s [popover visibility state](#)<sup>p887</sup> to [hidden](#)<sup>p887</sup>.
13. If *fireEvents* is *true*, then [queue a popover toggle event task](#)<sup>p889</sup> given *element*, "open", and "closed".
14. Let *previouslyFocusedElement* be *element*'s [previously focused element](#)<sup>p652</sup>.
15. If *previouslyFocusedElement* is not *null*, then:
  1. Set *element*'s [previously focused element](#)<sup>p652</sup> to *null*.

2. If *focusPreviousElement* is true and *document*'s [focused area of the document](#)<sup>p836</sup>'s [DOM anchor](#)<sup>p835</sup> is a [shadow-including inclusive descendant](#) of *element*, then run the [focusing steps](#)<sup>p842</sup> for *previouslyFocusedElement*; the viewport should not be scrolled by doing this step.

16. Run *cleanupSteps*.

The **`togglePopover(options)`** method steps are:

1. Let *force* be null.
2. If *options* is a boolean, set *force* to *options*.
3. Otherwise, if *options*["[force](#)<sup>p142</sup>"] [exists](#), set *force* to *options*["[force](#)<sup>p142</sup>"].
4. Let *invoker* be *options*["[source](#)<sup>p142</sup>"] if it [exists](#); otherwise, null.
5. If *this*'s [popover visibility state](#)<sup>p887</sup> is [showing](#)<sup>p887</sup>, and *force* is null or false, then run the [hide popover algorithm](#)<sup>p890</sup> given *this*, true, true, and true.
6. Otherwise, if *force* is null or true, then run [show popover](#)<sup>p888</sup> given *this*, true, and *invoker*.
7. Otherwise:
  1. Let *expectedToBeShowing* be true if *this*'s [popover visibility state](#)<sup>p887</sup> is [showing](#)<sup>p887</sup>; otherwise false.
  2. Run [check popover validity](#)<sup>p893</sup> given *expectedToBeShowing*, true, and null.
8. Return true if *this*'s [popover visibility state](#)<sup>p887</sup> is [showing](#)<sup>p887</sup>; otherwise false.

To **hide all popovers until**, given an [HTML element](#)<sup>p45</sup> or [Document](#)<sup>p130</sup> *endpoint*, a boolean *focusPreviousElement*, and a boolean *fireEvents*:

1. If *endpoint* is an [HTML element](#)<sup>p45</sup> and *endpoint* is not in the [popover showing state](#)<sup>p887</sup>, then return.
2. Let *document* be *endpoint*'s [node document](#).
3. Let *closeAllOpenPopovers* be an algorithm which performs the following steps:
  1. Let *popover* be *document*'s [topmost auto popover](#)<sup>p893</sup>.
  2. While *popover* is not null:
    1. Run the [hide popover algorithm](#)<sup>p890</sup> given *popover*, *focusPreviousElement*, *fireEvents*, and false.
    2. Set *popover* to *document*'s [topmost auto popover](#)<sup>p893</sup>.
4. If *endpoint* is a [Document](#)<sup>p130</sup>, then run *closeAllOpenPopovers* and return.
5. **Assert:** *endpoint*'s [popover](#)<sup>p886</sup> attribute is in the [auto](#)<sup>p887</sup> state.
6. Let *repeatingHide* be false.
7. Perform the following steps at least once:
  1. Let *lastToHide* be null.
  2. Let *foundEndpoint* be false.
  3. For each *popover* of *document*'s [showing auto popover list](#)<sup>p894</sup>:
    1. If *popover* is *endpoint*, then set *foundEndpoint* to true.
    2. Otherwise, if *foundEndpoint* is true, then set *lastToHide* to *popover* and [break](#).
  4. If *foundEndpoint* is false, then run *closeAllOpenPopovers* and return.
  5. While *lastToHide* is not null and *lastToHide*'s [popover visibility state](#)<sup>p887</sup> is [showing](#)<sup>p887</sup> and *document*'s [showing auto popover list](#)<sup>p894</sup> is not empty:
    1. Run the [hide popover algorithm](#)<sup>p890</sup> given *document*'s [showing auto popover list](#)<sup>p894</sup>'s last element, *focusPreviousElement*, *fireEvents*, and false.

6. Set `repeatingHide` to true if document's [showing auto popover list](#)<sup>p894</sup> contains `endpoint` and document's [showing auto popover list](#)<sup>p894</sup>'s last element is not `endpoint`, otherwise false.
7. If `repeatingHide` is true, then set `fireEvents` to false.

and keep performing them [while](#) `repeatingHide` is true.

#### Note

The [hide all popovers until algorithm](#)<sup>p891</sup> is used in several cases to hide all popovers that don't stay open when something happens. For example, during light-dismiss of a popover, this algorithm ensures that we close only the popovers that aren't related to the node clicked by the user.

To find the **topmost popover ancestor**, given a [Node](#) `newPopoverOrTopLayerElement`, an [HTML element](#)<sup>p45</sup> or null `invoker`, and a boolean `isPopover`, perform the following steps. They return an [HTML element](#)<sup>p45</sup> or null.

#### Note

The [topmost popover ancestor](#)<sup>p892</sup> algorithm will return the topmost (latest in the [showing auto popover list](#)<sup>p894</sup>) ancestor popover for the provided popover or top layer element. Popovers can be related to each other in several ways, creating a tree of popovers. There are two paths through which one popover (call it the "child" popover) can have a topmost ancestor popover (call it the "parent" popover):

1. The popovers are nested within each other in the node tree. In this case, the descendant popover is the "child" and its topmost ancestor popover is the "parent".
2. An invoking element (e.g., a [button](#)<sup>p566</sup>) has a [popovertarget](#)<sup>p894</sup> attribute pointing to a popover. In this case, the popover is the "child", and the popover subtree the invoking element is in is the "parent". The invoker has to be in a popover and reference an open popover.

In each of the relationships formed above, the parent popover has to be strictly earlier in the [showing auto popover list](#)<sup>p894</sup> than the child popover, or it does not form a valid ancestral relationship. This eliminates non-showing popovers and self-pointers (e.g., a popover containing an invoking element that points back to the containing popover), and it allows for the construction of a well-formed tree from the (possibly cyclic) graph of connections. Only [auto](#)<sup>p887</sup> popovers are considered.

If the provided element is a top layer element such as a [dialog](#)<sup>p646</sup> which is not showing as a popover, then [topmost popover ancestor](#)<sup>p892</sup> will only look in the node tree to find the first popover.

1. If `isPopover` is true:
  1. [Assert](#): `newPopoverOrTopLayerElement` is an [HTML element](#)<sup>p45</sup>.
  2. [Assert](#): `newPopoverOrTopLayerElement`'s [popover](#)<sup>p886</sup> attribute is not in the [no popover state](#)<sup>p887</sup> or the [manual](#)<sup>p887</sup> state.
  3. [Assert](#): `newPopoverOrTopLayerElement`'s [popover visibility state](#)<sup>p887</sup> is not in the [popover showing state](#)<sup>p887</sup>.
2. Otherwise:
  1. [Assert](#): `invoker` is null.
3. Let `popoverPositions` be an empty [ordered map](#).
4. Let `index` be 0.
5. Let `document` be `newPopoverOrTopLayerElement`'s [node document](#).
6. For each `popover` of `document`'s [showing auto popover list](#)<sup>p894</sup>:
  1. [Set](#) `popoverPositions[popover]` to `index`.
  2. Increment `index` by 1.
7. If `isPopover` is true, then [set](#) `popoverPositions[newPopoverOrTopLayerElement]` to `index`.
8. Increment `index` by 1.

9. Let *topmostPopoverAncestor* be null.
10. Let *checkAncestor* be an algorithm which performs the following steps given *candidate*:
  1. If *candidate* is null, then return.
  2. Let *candidateAncestor* be the result of running [nearest inclusive open popover](#)<sup>p893</sup> given *candidate*.
  3. If *candidateAncestor* is null, then return.
  4. Let *candidatePosition* be *popoverPositions*[*candidateAncestor*].
  5. If *topmostPopoverAncestor* is null or *popoverPositions*[*topmostPopoverAncestor*] is less than *candidatePosition*, then set *topmostPopoverAncestor* to *candidateAncestor*.
11. Run *checkAncestor* given *newPopoverOrTopLayerElement*'s parent node within the [flat tree](#).
12. Run *checkAncestor* given *invoker*.
13. Return *topmostPopoverAncestor*.

To find the **nearest inclusive open popover** given a [Node](#) *node*, perform the following steps. They return an [HTML element](#)<sup>p45</sup> or null.

1. Let *currentNode* be *node*.
2. While *currentNode* is not null:
  1. If *currentNode*'s [popover](#)<sup>p886</sup> attribute is in the [auto](#)<sup>p887</sup> state and *currentNode*'s [popover visibility state](#)<sup>p887</sup> is [showing](#)<sup>p887</sup>, then return *currentNode*.
  2. Set *currentNode* to *currentNode*'s parent in the [flat tree](#).
3. Return null.

To **find the topmost auto popover** given a [Document](#)<sup>p130</sup> *document*, perform the following steps. They return an [HTML element](#)<sup>p45</sup> or null.

1. If *document*'s [showing auto popover list](#)<sup>p894</sup> is not empty, then return *document*'s [showing auto popover list](#)<sup>p894</sup>'s last element.
2. Return null.

To perform the **popover focusing steps** for an [HTML element](#)<sup>p45</sup> *subject*:

1. If *subject* is a [dialog](#)<sup>p646</sup> element, then run the [dialog focusing steps](#)<sup>p650</sup> given *subject* and return.
2. If *subject* has the [autofocus](#)<sup>p848</sup> attribute, then let *control* be *subject*.
3. Otherwise, let *control* be the [autofocus delegate](#)<sup>p841</sup> for *subject* given "other".
4. If *control* is null, then return.
5. Run the [focusing steps](#)<sup>p842</sup> given *control*.
6. Let *topDocument* be the [active document](#)<sup>p998</sup> of *control*'s [node document](#)'s [browsing context](#)<sup>p999</sup>'s [top-level browsing context](#)<sup>p1001</sup>.
7. If *control*'s [node document](#)'s [origin](#) is not the [same](#)<sup>p899</sup> as the [origin](#) of *topDocument*, then return.
8. [Empty](#) *topDocument*'s [autofocus candidates](#)<sup>p848</sup>.
9. Set *topDocument*'s [autofocus processed flag](#)<sup>p848</sup> to true.

To **check popover validity** for an [HTML element](#)<sup>p45</sup> *element* given a boolean *expectedToBeShowing*, a boolean *throwExceptions*, and a [Document](#)<sup>p130</sup> or null *expectedDocument* perform the following steps. They throw an exception or return a boolean.

1. If *element*'s [popover](#)<sup>p886</sup> attribute is in the [no popover](#)<sup>p887</sup> state, then:
  1. If *throwExceptions* is true, then throw a ["NotSupportedError"](#) [DOMException](#).

2. Return false.

2. If any of the following are true:

- `expectedToBeShowing` is true and `element`'s `popover visibility state`<sup>p887</sup> is not `showing`<sup>p887</sup>; or
- `expectedToBeShowing` is false and `element`'s `popover visibility state`<sup>p887</sup> is not `hidden`<sup>p887</sup>,

then return false.

3. If any of the following are true:

- `element` is not `connected`;
- `element`'s `node document` is not `fully active`<sup>p1003</sup>;
- `expectedDocument` is not null and `element`'s `node document` is not `expectedDocument`;
- `element` is a `dialog`<sup>p646</sup> element and its `is modal`<sup>p652</sup> flag is set to true; or
- `element`'s `fullscreen flag` is set,

then:

1. If `throwExceptions` is true, then throw a `"InvalidStateError" DOMException`.
2. Return false.

4. Return true.

To get the **showing auto popover list** for a `Document`<sup>p138</sup> `document`:

1. Let `popovers` be « ».
2. For each `Element` `element` in `document`'s `top layer`: if `element`'s `popover`<sup>p886</sup> attribute is in the `auto state`<sup>p887</sup> and `element`'s `popover visibility state`<sup>p887</sup> is `showing`<sup>p887</sup>, then `append` `element` to `popovers`.
3. Return `popovers`.

### 6.12.1 The popover target attributes <sup>§ p89</sup><sub>4</sub>

`Buttons`<sup>p514</sup> may have the following content attributes:

- `popovertarget`
- `popovertargetaction`

If specified, the `popovertarget`<sup>p894</sup> attribute value must be the `ID` of an element with a `popover`<sup>p886</sup> attribute in the same `tree` as the `button`<sup>p514</sup> with the `popovertarget`<sup>p894</sup> attribute.

The `popovertargetaction`<sup>p894</sup> attribute is an `enumerated attribute`<sup>p76</sup> with the following keywords and states:

Keyword	State	Brief description
<code>toggle</code>	<code>toggle</code>	Shows or hides the targeted popover element.
<code>show</code>	<code>show</code>	Shows the targeted popover element.
<code>hide</code>	<code>hide</code>	Hides the targeted popover element.

The attribute's `missing value default`<sup>p76</sup> and `invalid value default`<sup>p76</sup> are both the `toggle`<sup>p894</sup> state.

#### Note

*Whenever possible ensure the popover element is placed immediately after its triggering element in the DOM. Doing so will help ensure that the popover is exposed in a logical programmatic reading order for users of assistive technology, such as screen readers.*

#### Example

The following shows how the [popovertarget](#)<sup>p894</sup> attribute in combination with the [popovertargetaction](#)<sup>p894</sup> attribute can be used to show and close a popover:

```
<button popovertarget="foo" popovertargetaction="show">
  Show a popover
</button>

<article popover="auto" id="foo">
  This is a popover article!
  <button popovertarget="foo" popovertargetaction="hide">Close</button>
</article>
```

If a [popovertargetaction](#)<sup>p894</sup> attribute is not specified, the default action will be to toggle the associated popover. The following shows how only specifying the [popovertarget](#)<sup>p894</sup> attribute on its invoking button can toggle a manual popover between its opened and closed states. A manual popover will not respond to [light dismiss](#)<sup>p896</sup> or [close requests](#)<sup>p863</sup>:

```
<input type="button" popovertarget="foo" value="Toggle the popover">

<div popover=manual id="foo">
  This is a popover!
</div>
```

[DOM interface](#)<sup>p147</sup>:

```
IDL interface mixin PopoverInvokerElement {
  [CEReactions] attribute Element? popoverTargetElement;
  [CEReactions] attribute DOMString popoverTargetAction;
};
```

The **popoverTargetElement** IDL attribute must [reflect](#)<sup>p104</sup> the [popovertarget](#)<sup>p894</sup> attribute.

The **popoverTargetAction** IDL attribute must [reflect](#)<sup>p104</sup> the [popovertargetaction](#)<sup>p894</sup> attribute, [limited to only known values](#)<sup>p105</sup>.

To run the **popover target attribute activation behavior** given a [Node](#) *node* and a [Node](#) *eventTarget*:

1. Let *popover* be *node*'s [popover target element](#)<sup>p895</sup>.
2. If *popover* is null, then return.
3. If *eventTarget* is a [shadow-including inclusive descendant](#) of *popover* and *popover* is a [shadow-including descendant](#) of *node*, then return.
4. If *node*'s [popovertargetaction](#)<sup>p894</sup> attribute is in the [show](#)<sup>p894</sup> state and *popover*'s [popover visibility state](#)<sup>p887</sup> is [showing](#)<sup>p887</sup>, then return.
5. If *node*'s [popovertargetaction](#)<sup>p894</sup> attribute is in the [hide](#)<sup>p894</sup> state and *popover*'s [popover visibility state](#)<sup>p887</sup> is [hidden](#)<sup>p887</sup>, then return.
6. If *popover*'s [popover visibility state](#)<sup>p887</sup> is [showing](#)<sup>p887</sup>, then run the [hide popover algorithm](#)<sup>p890</sup> given *popover*, true, true, and false.
7. Otherwise, if *popover*'s [popover visibility state](#)<sup>p887</sup> is [hidden](#)<sup>p887</sup> and the result of running [check popover validity](#)<sup>p893</sup> given *popover*, false, false, and null is true, then run [show popover](#)<sup>p888</sup> given *popover*, false, and *node*.

To get the **popover target element** given a [Node](#) *node*, perform the following steps. They return an [HTML element](#)<sup>p45</sup> or null.

1. If *node* is not a [button](#)<sup>p514</sup>, then return null.
2. If *node* is [disabled](#)<sup>p601</sup>, then return null.
3. If *node* has a [form owner](#)<sup>p598</sup> and *node* is a [submit button](#)<sup>p514</sup>, then return null.
4. Let *popoverElement* be the result of running *node*'s [get the popovertarget-associated element](#)<sup>p108</sup>.

5. If *popoverElement* is null, then return null.
6. If *popoverElement*'s [popover<sup>p886</sup>](#) attribute is in the [no popover<sup>p887</sup>](#) state, then return null.
7. Return *popoverElement*.

## 6.12.2 Popover light dismiss <sup>p889</sup>

### Note

"Light dismiss" means that clicking outside of a popover whose [popover<sup>p886</sup>](#) attribute is in the [auto<sup>p887</sup>](#) state will close the popover. This is in addition to how such popovers respond to [close requests<sup>p863</sup>](#).

To **light dismiss open popovers**, given an [Event](#) event:

1. [Assert](#): event's [isTrusted](#) attribute is true.
2. Let *target* be event's [target](#).
3. Let *document* be *target*'s [node document](#).
4. Let *topmostPopover* be the result of running [topmost auto popover<sup>p893</sup>](#) given *document*.
5. If *topmostPopover* is null, then return.
6. If event is a [PointerEvent](#) and event's [type](#) is "[pointerdown](#)", then: set *document*'s [popover pointerdown target<sup>p887</sup>](#) to the result of running [topmost clicked popover<sup>p896</sup>](#) given *target*.
7. If event is a [PointerEvent](#) and event's [type](#) is "[pointerup](#)", then:
  1. Let *ancestor* be the result of running [topmost clicked popover<sup>p896</sup>](#) given *target*.
  2. Let *sameTarget* be true if *ancestor* is *document*'s [popover pointerdown target<sup>p887</sup>](#).
  3. Set *document*'s [popover pointerdown target<sup>p887</sup>](#) to null.
  4. If *ancestor* is null, then set *ancestor* to *document*.
  5. If *sameTarget* is true, then run [hide all popovers until<sup>p891</sup>](#) given *ancestor*, false, and true.

[Light dismiss open popovers<sup>p896</sup>](#) will be called by the [Pointer Events spec](#) when the user clicks or touches anywhere on the page.

To find the **topmost clicked popover**, given a [Node](#) *node*:

1. Let *clickedPopover* be the result of running [nearest inclusive open popover<sup>p893</sup>](#) given *node*.
2. Let *invokerPopover* be the result of running [nearest inclusive target popover for invoker<sup>p896</sup>](#) given *node*.
3. Let *getStackPosition* be an algorithm which performs the following steps given an [HTML element<sup>p45</sup>](#) *popover*:
  1. Let *popoverList* be *popover*'s [node document](#)'s [showing auto popover list<sup>p894</sup>](#).
  2. If *popover* is in *popoverList*, then return the index of *popover* in *popoverList* + 1.
  3. Return 0.
4. If the result of running *getStackPosition* given *clickedPopover* is greater than the result of running *getStackPosition* given *invokerPopover*, then return *clickedPopover*.
5. Return *invokerPopover*.

To find the **nearest inclusive target popover for invoker** given a [Node](#) *node*:

1. Let *currentNode* be *node*.
2. While *currentNode* is not null:

1. Let *targetPopover* be *currentNode*'s [popover target element](#)<sup>p895</sup>.
2. If *targetPopover* is not null and *targetPopover*'s [popover](#)<sup>p886</sup> attribute is in the [auto](#)<sup>p887</sup> state and *targetPopover*'s [popover visibility state](#)<sup>p887</sup> is [showing](#)<sup>p887</sup>, then return *targetPopover*.
3. Set *currentNode* to *currentNode*'s ancestor in the [flat tree](#).

## 7 Loading web pages §<sup>p89</sup><sub>8</sub>

This section describes features that apply most directly to web browsers. Having said that, except where specified otherwise, the requirements defined in this section *do* apply to all user agents, whether they are web browsers or not.

### 7.1 Supporting concepts §<sup>p89</sup><sub>8</sub>

#### 7.1.1 Origins §<sup>p89</sup><sub>8</sub>

Origins are the fundamental currency of the web's security model. Two actors in the web platform that share an origin are assumed to trust each other and to have the same authority. Actors with differing origins are considered potentially hostile versus each other, and are isolated from each other to varying degrees.

##### Example

For example, if Example Bank's web site, hosted at `bank.example.com`, tries to examine the DOM of Example Charity's web site, hosted at `charity.example.org`, a `"SecurityError" DOMException` will be raised.

An **origin** is one of the following:

##### An opaque origin

An internal value, with no serialization it can be recreated from (it is serialized as `"null"` per [serialization of an origin<sup>p898</sup>](#)), for which the only meaningful operation is testing for equality.

##### A tuple origin

A [tuple<sup>p898</sup>](#) consists of:

- A **scheme** (an [ASCII string](#)).
- A **host** (a [host](#)).
- A **port** (null or a 16-bit unsigned integer).
- A **domain** (null or a [domain](#)). Null unless stated otherwise.

##### Note

[Origins<sup>p898</sup>](#) can be shared, e.g., among multiple [Document<sup>p130</sup>](#) objects. Furthermore, [origins<sup>p898</sup>](#) are generally immutable. Only the [domain<sup>p898</sup>](#) of a [tuple origin<sup>p898</sup>](#) can be changed, and only through the [document.domain<sup>p901</sup>](#) API.

The **effective domain** of an [origin<sup>p898</sup>](#) origin is computed as follows:

1. If origin is an [opaque origin<sup>p898</sup>](#), then return null.
2. If origin's [domain<sup>p898</sup>](#) is non-null, then return origin's [domain<sup>p898</sup>](#).
3. Return origin's [host<sup>p898</sup>](#).

The **serialization of an origin** is the string obtained by applying the following algorithm to the given [origin<sup>p898</sup>](#) origin:

1. If origin is an [opaque origin<sup>p898</sup>](#), then return `"null"`.
2. Otherwise, let *result* be origin's [scheme<sup>p898</sup>](#).
3. Append `"/"` to *result*.
4. Append origin's [host<sup>p898</sup>](#), [serialized](#), to *result*.
5. If origin's [port<sup>p898</sup>](#) is non-null, append a U+003A COLON character (`:`), and origin's [port<sup>p898</sup>](#), [serialized](#), to *result*.
6. Return *result*.

### Example

The [serialization<sup>p898</sup>](#) of ("https", "xn--maraa-rta.example", null, null) is "https://xn--maraa-rta.example".

### Note

*There used to also be a Unicode serialization of an origin. However, it was never widely adopted.*

Two [origins<sup>p898</sup>](#), *A* and *B*, are said to be **same origin** if the following algorithm returns true:

1. If *A* and *B* are the same [opaque origin<sup>p898</sup>](#), then return true.
2. If *A* and *B* are both [tuple origins<sup>p898</sup>](#) and their [schemes<sup>p898</sup>](#), [hosts<sup>p898</sup>](#), and [port<sup>p898</sup>](#) are identical, then return true.
3. Return false.

Two [origins<sup>p898</sup>](#), *A* and *B*, are said to be **same origin-domain** if the following algorithm returns true:

1. If *A* and *B* are the same [opaque origin<sup>p898</sup>](#), then return true.
2. If *A* and *B* are both [tuple origins<sup>p898</sup>](#):
  1. If *A* and *B*'s [schemes<sup>p898</sup>](#) are identical, and their [domains<sup>p898</sup>](#) are identical and non-null, then return true.
  2. Otherwise, if *A* and *B* are [same origin<sup>p899</sup>](#) and their [domains<sup>p898</sup>](#) are both null, return true.
3. Return false.

### Example

<b>A</b>	<b>B</b>	<b>same origin<sup>p899</sup></b>	<b>same origin-domain<sup>p899</sup></b>
("https", "example.org", null, null)	("https", "example.org", null, null)	✓	✓
("https", "example.org", 314, null)	("https", "example.org", 420, null)	✗	✗
("https", "example.org", 314, "example.org")	("https", "example.org", 420, "example.org")	✗	✓
("https", "example.org", null, null)	("https", "example.org", null, "example.org")	✓	✗
("https", "example.org", null, "example.org")	("http", "example.org", null, "example.org")	✗	✗

#### 7.1.1.1 Sites <sup>p899</sup><sub>9</sub>

A **scheme-and-host** is a [tuple](#) of a **scheme** (an [ASCII string](#)) and a **host** (a [host](#)).

A **site** is an [opaque origin<sup>p898</sup>](#) or a [scheme-and-host<sup>p899</sup>](#).

To **obtain a site**, given an origin *origin*, run these steps:

1. If *origin* is an [opaque origin<sup>p898</sup>](#), then return *origin*.
2. If *origin*'s [host<sup>p898</sup>](#)'s [registrable domain](#) is null, then return (*origin*'s [scheme<sup>p898</sup>](#), *origin*'s [host<sup>p898</sup>](#)).
3. Return (*origin*'s [scheme<sup>p898</sup>](#), *origin*'s [host<sup>p898</sup>](#)'s [registrable domain](#)).

Two [sites<sup>p899</sup>](#), *A* and *B*, are said to be **same site** if the following algorithm returns true:

1. If *A* and *B* are the same [opaque origin<sup>p898</sup>](#), then return true.
2. If *A* or *B* is an [opaque origin<sup>p898</sup>](#), then return false.
3. If *A*'s and *B*'s [scheme<sup>p899</sup>](#) values are different, then return false.
4. If *A*'s and *B*'s [host<sup>p899</sup>](#) values are not [equal](#), then return false.
5. Return true.

The **serialization of a site** is the string obtained by applying the following algorithm to the given [site<sup>p899</sup>](#) *site*:

1. If *site* is an [opaque origin](#)<sup>p898</sup>, then return "null".
2. Let *result* be *site*[0].
3. Append "://" to *result*.
4. Append *site*[1], [serialized](#), to *result*.
5. Return *result*.

#### Warning!

*It needs to be clear from context that the serialized value is a site, not an origin, as there is not necessarily a syntactic difference between the two. For example, the origin ("https", "shop.example", null, null) and the site ("https", "shop.example") have the same serialization: "https://shop.example".*

Two [origins](#)<sup>p898</sup>, *A* and *B*, are said to be **schemelessly same site** if the following algorithm returns true:

1. If *A* and *B* are the same [opaque origin](#)<sup>p898</sup>, then return true.
2. If *A* and *B* are both [tuple origins](#)<sup>p898</sup>, then:
  1. Let *hostA* be *A*'s [host](#)<sup>p898</sup>, and let *hostB* be *B*'s [host](#)<sup>p898</sup>.
  2. If *hostA* [equals](#) *hostB* and *hostA*'s [registrable domain](#) is null, then return true.
  3. If *hostA*'s [registrable domain equals](#) *hostB*'s [registrable domain](#) and is non-null, then return true.
3. Return false.

Two [origins](#)<sup>p898</sup>, *A* and *B*, are said to be **same site** if the following algorithm returns true:

1. Let *siteA* be the result of [obtaining a site](#)<sup>p899</sup> given *A*.
2. Let *siteB* be the result of [obtaining a site](#)<sup>p899</sup> given *B*.
3. If *siteA* is [same site](#)<sup>p899</sup> with *siteB*, then return true.
4. Return false.

#### Note

*Unlike the [same origin](#)<sup>p899</sup> and [same origin-domain](#)<sup>p899</sup> concepts, for [schemelessly same site](#)<sup>p900</sup> and [same site](#)<sup>p900</sup>, the [port](#)<sup>p898</sup> and [domain](#)<sup>p898</sup> components are ignored.*

#### Warning!

*For the reasons explained in URL, the [same site](#)<sup>p900</sup> and [schemelessly same site](#)<sup>p900</sup> concepts should be avoided when possible, in favor of [same origin](#)<sup>p899</sup> checks.*

#### Example

Given that [wildlife.museum](#), [museum](#), and [com](#) are [public suffixes](#) and that [example.com](#) is not:

<b>A</b>	<b>B</b>	<b><a href="#">schemelessly same site</a><sup>p900</sup></b>	<b><a href="#">same site</a><sup>p900</sup></b>
("https", "example.com")	("https", "sub.example.com")	✓	✓
("https", "example.com")	("https", "sub.other.example.com")	✓	✓
("https", "example.com")	("http", "non-secure.example.com")	✓	✗
("https", "r.wildlife.museum")	("https", "sub.r.wildlife.museum")	✓	✓
("https", "r.wildlife.museum")	("https", "sub.other.r.wildlife.museum")	✓	✓
("https", "r.wildlife.museum")	("https", "other.wildlife.museum")	✗	✗
("https", "r.wildlife.museum")	("https", "wildlife.museum")	✗	✗
("https", "wildlife.museum")	("https", "wildlife.museum")	✓	✓
("https", "example.com")	("https", "example.com.")	✗	✗

(Here we have omitted the [port](#)<sup>p898</sup> and [domain](#)<sup>p898</sup> components since they are not considered.)

### 7.1.1.2 Relaxing the same-origin restriction §<sup>p90</sup><sub>1</sub>

For web developers (non-normative)

`document.domainp901 [ = domain ]`

Returns the current domain used for security checks.

Can be set to a value that removes subdomains, to change the [origin<sup>p898</sup>](#)'s [domain<sup>p898</sup>](#) to allow pages on other subdomains of the same domain (if they do the same thing) to access each other. This enables pages on different hosts of a domain to synchronously access each other's DOMs.

In sandboxed [iframe<sup>p390</sup>](#)s, [Document<sup>p130</sup>](#)s with [opaque origins<sup>p898</sup>](#), and [Document<sup>p130</sup>](#)s without a [browsing context<sup>p999</sup>](#), the setter will throw a ["SecurityError"](#) exception. In cases where [crossOriginIsolated<sup>p1149</sup>](#) or [originAgentCluster<sup>p903</sup>](#) return true, the setter will do nothing.

Avoid using the `document.domainp901` setter. It undermines the security protections provided by the same-origin policy. This is especially acute when using shared hosting; for example, if an untrusted third party is able to host an HTTP server at the same IP address but on a different port, then the same-origin protection that normally protects two different sites on the same host will fail, as the ports are ignored when comparing origins after the `document.domainp901` setter has been used.

Because of these security pitfalls, this feature is in the process of being removed from the web platform. (This is a long process that takes many years.)

Instead, use [postMessage\(\)<sup>p1201</sup>](#) or [MessageChannel<sup>p1204</sup>](#) objects to communicate across origins in a safe manner.

The `domain` getter steps are:

1. Let *effectiveDomain* be [this's origin's effective domain<sup>p898</sup>](#).
2. If *effectiveDomain* is null, then return the empty string.
3. Return *effectiveDomain*, [serialized](#).

The `domainp901` setter steps are:

1. If [this's browsing context<sup>p999</sup>](#) is null, then throw a ["SecurityError" DOMException](#).
2. If [this's active sandboxing flag set<sup>p917</sup>](#) has its [sandboxed document.domain browsing context flag<sup>p915</sup>](#) set, then throw a ["SecurityError" DOMException](#).
3. Let *effectiveDomain* be [this's origin's effective domain<sup>p898</sup>](#).
4. If *effectiveDomain* is null, then throw a ["SecurityError" DOMException](#).
5. If the given value [is not a registrable domain suffix of and is not equal to<sup>p901</sup>](#) *effectiveDomain*, then throw a ["SecurityError" DOMException](#).
6. If the [surrounding agent's agent cluster's is origin-keyed<sup>p1073</sup>](#) is true, then return.
7. Set [this's origin's domain<sup>p898</sup>](#) to the result of [parsing](#) the given value.

To determine if a [scalar value string](#) *hostSuffixString* is a **registrable domain suffix of or is equal to** a [host](#) *originalHost*:

1. If *hostSuffixString* is the empty string, then return false.
2. Let *hostSuffix* be the result of [parsing](#) *hostSuffixString*.
3. If *hostSuffix* is failure, then return false.
4. If *hostSuffix* does not [equal](#) *originalHost*, then:
  1. If *hostSuffix* or *originalHost* is not a [domain](#), then return false.

#### Note

This excludes [hosts](#) that are [IP addresses](#).

2. If *hostSuffix*, prefixed by U+002E (.), does not match the end of *originalHost*, then return false.

3. If any of the following are true:

- *hostSuffix* [equals](#) *hostSuffix*'s [public suffix](#); or
- *hostSuffix*, prefixed by U+002E (.), matches the end of *originalHost*'s [public suffix](#),

then return false. [\[URL\] p1483](#)

4. [Assert](#): *originalHost*'s [public suffix](#), prefixed by U+002E (.), matches the end of *hostSuffix*.

5. Return true.

#### Example

<i>hostSuffixString</i>	<i>originalHost</i>	Outcome of <a href="#">is a registrable domain suffix of or is equal to</a> p901	Notes
"0.0.0.0"	0.0.0.0	✓	
"0x10203"	0.1.2.3	✓	
"[0::1]"	::1	✓	
"example.com"	example.com	✓	
"example.com"	example.com.	✗	Trailing dot is significant.
"example.com."	example.com	✗	
"example.com"	www.example.com	✓	
"com"	example.com	✗	At the time of writing, com is a public suffix.
"example"	example	✓	
"compute.amazonaws.com"	example.compute.amazonaws.com	✗	At the time of writing, *.compute.amazonaws.com is a public suffix.
"example.compute.amazonaws.com"	www.example.compute.amazonaws.com	✗	
"amazonaws.com"	www.example.compute.amazonaws.com	✗	
"amazonaws.com"	test.amazonaws.com	✓	At the time of writing, amazonaws.com is a registrable domain.

### 7.1.2 Origin-keyed agent clusters § p902

For web developers (non-normative)

**window.originAgentCluster** p903

Returns true if this [Window](#) p922 belongs to an [agent cluster](#) which is [origin](#) p898-keyed p1073, in the manner described in this section.

A [Document](#) p130 delivered over a [secure context](#) p1084 can request that it be placed in an [origin](#) p898-keyed p1073 [agent cluster](#), by using the ``Origin-Agent-Cluster`` HTTP response header. This header is a [structured header](#) whose value must be a [boolean](#). [\[STRUCTURED-FIELDS\] p1482](#)

Per the processing model in the [create and initialize a new Document object](#) p1056, values that are not the [structured header boolean](#) true value (i.e., ``?1``) will be ignored.

The consequences of using this header are that the resulting [Document](#) p130's [agent cluster key](#) p1073 is its [origin](#), instead of the [corresponding site](#) p899. In terms of observable effects, this means that attempting to [relax the same-origin restriction](#) p901 using [document.domain](#) p901 will instead do nothing, and it will not be possible to send [WebAssembly.Module](#) objects to cross-origin [Document](#) p130s (even if they are [same site](#) p900). Behind the scenes, this isolation can allow user agents to allocate implementation-specific resources corresponding to [agent clusters](#), such as processes or threads, more efficiently.

Note that within a [browsing context group](#) p1002, the ``Origin-Agent-Cluster`` p902 header can never cause same-origin [Document](#) p130 objects to end up in different [agent clusters](#), even if one sends the header and the other doesn't. This is prevented by means of the [historical agent cluster key map](#) p1002.

#### Note

This means that the [originAgentCluster](#) p903 getter can return false, even if the header is set, if the header was omitted on a previously-loaded same-origin page in the same [browsing context group](#) p1002. Similarly, it can return true even when the header is not set.

The **originAgentCluster** getter steps are to return the [surrounding agent's agent cluster's is origin-keyed](#)<sup>p1073</sup>.

#### Note

[Document](#)<sup>p130</sup>s with an [opaque origin](#)<sup>p898</sup> can be considered unconditionally origin-keyed; for them the header has no effect, and the [originAgentCluster](#)<sup>p903</sup> getter will always return true.

#### Note

Similarly, [Document](#)<sup>p130</sup>s whose [agent cluster's cross-origin isolation mode](#)<sup>p1073</sup> is not "[none](#)"<sup>p1002</sup> are automatically origin-keyed. The [`Origin-Agent-Cluster`](#)<sup>p902</sup> header might be useful as an additional hint to implementations about resource allocation, since the [`Cross-Origin-Opener-Policy`](#)<sup>p904</sup> and [`Cross-Origin-Embedder-Policy`](#)<sup>p913</sup> headers used to achieve cross-origin isolation are more about ensuring that everything in the same address space opts in to being there. But adding it would have no additional observable effects on author code.

### 7.1.3 Cross-origin opener policies <sup>§<sup>p90</sup><sub>3</sub></sup>

An **opener policy value** allows a document which is navigated to in a [top-level browsing context](#)<sup>p1001</sup> to force the creation of a new [top-level browsing context](#)<sup>p1001</sup>, and a corresponding [group](#)<sup>p1002</sup>. The possible values are:

#### "unsafe-none"

This is the (current) default and means that the document will occupy the same [top-level browsing context](#)<sup>p1001</sup> as its predecessor, unless that document specified a different [opener policy](#)<sup>p904</sup>.

#### "same-origin-allow-popups"

This forces the creation of a new [top-level browsing context](#)<sup>p1001</sup> for the document, unless its predecessor specified the same [opener policy](#)<sup>p904</sup> and they are [same origin](#)<sup>p899</sup>.

#### "same-origin"

This behaves the same as "[same-origin-allow-popups](#)"<sup>p903</sup>, with the addition that any [auxiliary browsing context](#)<sup>p999</sup> created needs to contain [same origin](#)<sup>p899</sup> documents that also have the same [opener policy](#)<sup>p904</sup> or it will appear closed to the opener.

#### "same-origin-plus-COEP"

This behaves the same as "[same-origin](#)"<sup>p903</sup>, with the addition that it sets the (new) [top-level browsing context](#)<sup>p1001</sup>'s [group](#)<sup>p1002</sup>'s [cross-origin isolation mode](#)<sup>p1002</sup> to one of "[logical](#)"<sup>p1002</sup> or "[concrete](#)"<sup>p1002</sup>.

#### Note

"[same-origin-plus-COEP](#)"<sup>p903</sup> cannot be directly set via the [`Cross-Origin-Opener-Policy`](#)<sup>p904</sup> header, but results from a combination of setting both [`Cross-Origin-Opener-Policy`](#)<sup>p904</sup>: [same-origin](#)<sup>p903</sup> and a [`Cross-Origin-Embedder-Policy`](#)<sup>p913</sup> header whose value is [compatible with cross-origin isolation](#)<sup>p912</sup> together.

#### "noopener-allow-popups"

This forces the creation of a new [top-level browsing context](#)<sup>p1001</sup> for the document, regardless of its predecessor.

#### Note

While including a [noopener-allow-popups](#)<sup>p903</sup> value severs the opener relationship between the document on which it is applied and its opener, it does not create a robust security boundary between those same-origin documents.

Other risks from same-origin applications include:

- Same-origin requests fetching the document's content — could be mitigated through Fetch Metadata filtering. [\[FETCHMETADATA\]](#)<sup>p1478</sup>
- Same-origin framing - could be mitigated through [X-Frame-Options](#)<sup>p1068</sup> or CSP [frame-ancestors](#).
- JavaScript accessible cookies - can be mitigated by ensuring all cookies are httpOnly.
- [localStorage](#)<sup>p1255</sup> access to sensitive data.
- Service worker installation.

- [Cache API](#) manipulation or access to sensitive data. [\[SW\]](#)<sup>p1482</sup>
- `postMessage` or [BroadcastChannel](#)<sup>p1209</sup> messaging that exposes sensitive information.
- Autofill which may not require user interaction for same-origin documents.

Developers using [noopener-allow-popups](#)<sup>p903</sup> need to make sure that their sensitive applications don't rely on client-side features accessible to other same-origin documents, e.g., [localStorage](#)<sup>p1255</sup> and other client-side storage APIs, [BroadcastChannel](#)<sup>p1209</sup> and related same-origin communication mechanisms. They also need to make sure that their server-side endpoints don't return sensitive data to non-navigation requests, whose response content is accessible to same-origin documents.

An **opener policy** consists of:

- A **value**, which is an [opener policy value](#)<sup>p903</sup>, initially "[unsafe-none](#)"<sup>p903</sup>.
- A **reporting endpoint**, which is string or null, initially null.
- A **report-only value**, which is an [opener policy value](#)<sup>p903</sup>, initially "[unsafe-none](#)"<sup>p903</sup>.
- A **report-only reporting endpoint**, which is a string or null, initially null.

To **match opener policy values**, given an [opener policy value](#)<sup>p903</sup> `documentCOOP`, an [origin](#)<sup>p898</sup> `documentOrigin`, an [opener policy value](#)<sup>p903</sup> `responseCOOP`, and an [origin](#)<sup>p898</sup> `responseOrigin`:

1. If `documentCOOP` is "[unsafe-none](#)"<sup>p903</sup> and `responseCOOP` is "[unsafe-none](#)"<sup>p903</sup>, then return true.
2. If `documentCOOP` is "[unsafe-none](#)"<sup>p903</sup> or `responseCOOP` is "[unsafe-none](#)"<sup>p903</sup>, then return false.
3. If `documentCOOP` is `responseCOOP` and `documentOrigin` is [same origin](#)<sup>p899</sup> with `responseOrigin`, then return true.
4. Return false.

#### 7.1.3.1 The headers <sup>p90</sup><sub>4</sub>

A [Document](#)<sup>p130</sup>'s [cross-origin opener policy](#)<sup>p131</sup> is derived from the ``Cross-Origin-Opener-Policy`` and ``Cross-Origin-Opener-Policy-Report-Only`` HTTP response headers. These headers are [structured headers](#) whose value must be a [token](#). [\[STRUCTURED-FIELDS\]](#)<sup>p1482</sup>

The valid [token](#) values are the [opener policy values](#)<sup>p903</sup>. The token may also have attached [parameters](#); of these, the "[report-to](#)" parameter can have a [valid URL string](#) identifying an appropriate reporting endpoint. [\[REPORTING\]](#)<sup>p1480</sup>

#### Note

*Per the processing model described below, user agents will ignore this header if it contains an invalid value. Likewise, user agents will ignore this header if the value cannot be parsed as a [token](#).*

To **obtain an opener policy** given a [response](#) `response` and an [environment](#)<sup>p1075</sup> `reservedEnvironment`:

1. Let `policy` be a new [opener policy](#)<sup>p904</sup>.
2. If `reservedEnvironment` is a [non-secure context](#)<sup>p1084</sup>, then return `policy`.
3. Let `parsedItem` be the result of [getting a structured field value](#) given ``Cross-Origin-Opener-Policy``<sup>p904</sup> and "item" from `response`'s [header list](#).
4. If `parsedItem` is not null, then:
  1. If `parsedItem[0]` is "[same-origin](#)"<sup>p903</sup>, then:
    1. Let `coop` be the result of [obtaining a cross-origin embedder policy](#)<sup>p913</sup> from `response` and `reservedEnvironment`.

2. If `coop`'s [value](#)<sup>p912</sup> is [compatible with cross-origin isolation](#)<sup>p912</sup>, then set `policy`'s [value](#)<sup>p904</sup> to "[same-origin-plus-COEP](#)<sup>p903</sup>".
3. Otherwise, set `policy`'s [value](#)<sup>p904</sup> to "[same-origin](#)<sup>p903</sup>".
2. If `parsedItem`[0] is "[same-origin-allow-popups](#)<sup>p903</sup>", then set `policy`'s [value](#)<sup>p904</sup> to "[same-origin-allow-popups](#)<sup>p903</sup>".
3. If `parsedItem`[0] is "[noopener-allow-popups](#)<sup>p903</sup>", then set `policy`'s [value](#)<sup>p904</sup> to "[noopener-allow-popups](#)<sup>p903</sup>".
4. If `parsedItem`[1][["report-to"](#)<sup>p904</sup>] [exists](#) and it is a string, then set `policy`'s [reporting endpoint](#)<sup>p904</sup> to `parsedItem`[1][["report-to"](#)<sup>p904</sup>].
5. Set `parsedItem` to the result of [getting a structured field value](#) given ``Cross-Origin-Opener-Policy-Report-Only`p904` and `"item"` from `response`'s [header list](#).
6. If `parsedItem` is not null, then:
  1. If `parsedItem`[0] is "[same-origin](#)<sup>p903</sup>", then:
    1. Let `coop` be the result of [obtaining a cross-origin embedder policy](#)<sup>p913</sup> from `response` and `reservedEnvironment`.
    2. If `coop`'s [value](#)<sup>p912</sup> is [compatible with cross-origin isolation](#)<sup>p912</sup> or `coop`'s [report-only value](#)<sup>p912</sup> is [compatible with cross-origin isolation](#)<sup>p912</sup>, then set `policy`'s [report-only value](#)<sup>p904</sup> to "[same-origin-plus-COEP](#)<sup>p903</sup>".

**Note**

*Report only COOP also considers report-only COEP to assign the special "[same-origin-plus-COEP](#)<sup>p903</sup>" value. This allows developers more freedom in the order of deployment of COOP and COEP.*
  3. Otherwise, set `policy`'s [report-only value](#)<sup>p904</sup> to "[same-origin](#)<sup>p903</sup>".
  2. If `parsedItem`[0] is "[same-origin-allow-popups](#)<sup>p903</sup>", then set `policy`'s [report-only value](#)<sup>p904</sup> to "[same-origin-allow-popups](#)<sup>p903</sup>".
  3. If `parsedItem`[1][["report-to"](#)<sup>p904</sup>] [exists](#) and it is a string, then set `policy`'s [report-only reporting endpoint](#)<sup>p904</sup> to `parsedItem`[1][["report-to"](#)<sup>p904</sup>].
7. Return `policy`.

### 7.1.3.2 Browsing context group switches due to opener policy <sup>§ p905</sup>

To **check if popup COOP values require a browsing context group switch**, given two [origins](#)<sup>p898</sup> `responseOrigin` and `activeDocumentNavigationOrigin`, and two [opener policy values](#)<sup>p904</sup> `responseCOOPValue` and `activeDocumentCOOPValue`:

1. `responseCOOPValue` is "[noopener-allow-popups](#)<sup>p903</sup>", then return true.
2. If all of the following are true:
  - `activeDocumentCOOPValue`'s [value](#)<sup>p904</sup> is "[same-origin-allow-popups](#)<sup>p903</sup>" or "[noopener-allow-popups](#)<sup>p903</sup>"; and
  - `responseCOOPValue` is "[unsafe-none](#)<sup>p903</sup>",
 then return false.
3. If the result of [matching](#)<sup>p904</sup> `activeDocumentCOOPValue`, `activeDocumentNavigationOrigin`, `responseCOOPValue`, and `responseOrigin` is true, then return false.
4. Return true.

To **check if COOP values require a browsing context group switch**, given a boolean `isInitialAboutBlank`, two [origins](#)<sup>p898</sup> `responseOrigin` and `activeDocumentNavigationOrigin`, and two [opener policy values](#)<sup>p904</sup> `responseCOOPValue` and `activeDocumentCOOPValue`:

1. If `isInitialAboutBlank` is true, then return the result of [checking if popup COOP values requires a browsing context group](#)

[switch](#)<sup>p905</sup> with *responseOrigin*, *activeDocumentNavigationOrigin*, *responseCOOPValue*, and *activeDocumentCOOPValue*.

#### Note

2. *Here we are dealing with a non-popup navigation.*

If the result of [matching](#)<sup>p904</sup> *activeDocumentCOOPValue*, *activeDocumentNavigationOrigin*, *responseCOOPValue*, and *responseOrigin* is true, then return false.

3. Return true.

To **check if enforcing report-only COOP would require a browsing context group switch**, given a boolean *isInitialAboutBlank*, two [origins](#)<sup>p898</sup> *responseOrigin*, *activeDocumentNavigationOrigin*, and two [opener policies](#)<sup>p904</sup> *responseCOOP* and *activeDocumentCOOP*:

1. If the result of [checking if COOP values require a browsing context group switch](#)<sup>p905</sup> given *isInitialAboutBlank*, *responseOrigin*, *activeDocumentNavigationOrigin*, *responseCOOP*'s [report-only value](#)<sup>p904</sup> and *activeDocumentCOOPReportOnly*'s [report-only value](#)<sup>p904</sup> is false, then return false.

#### Note

*Matching report-only policies allows a website to specify the same report-only opener policy on all its pages and not receive violation reports for navigations between these pages.*

2. If the result of [checking if COOP values require a browsing context group switch](#)<sup>p905</sup> given *isInitialAboutBlank*, *responseOrigin*, *activeDocumentNavigationOrigin*, *responseCOOP*'s [value](#)<sup>p904</sup> and *activeDocumentCOOPReportOnly*'s [report-only value](#)<sup>p904</sup> is true, then return true.
3. If the result of [checking if COOP values require a browsing context group switch](#)<sup>p905</sup> given *isInitialAboutBlank*, *responseOrigin*, *activeDocumentNavigationOrigin*, *responseCOOP*'s [report-only value](#)<sup>p904</sup> and *activeDocumentCOOPReportOnly*'s [value](#)<sup>p904</sup> is true, then return true.
4. Return false.

An **opener policy enforcement result** is a [struct](#) with the following [items](#):

- A boolean **needs a browsing context group switch**, initially false.
- A boolean **would need a browsing context group switch due to report-only**, initially false.
- A [URL](#) **url**.
- An [origin](#)<sup>p898</sup> **origin**.
- An [opener policy](#)<sup>p904</sup> **opener policy**.
- A boolean **current context is navigation source**, initially false.

To **enforce a response's opener policy**, given a [browsing context](#)<sup>p998</sup> *browsingContext*, a [URL](#) *responseURL*, an [origin](#)<sup>p898</sup> *responseOrigin*, an [opener policy](#)<sup>p904</sup> *responseCOOP*, an [opener policy enforcement result](#)<sup>p906</sup> *currentCOOPEnforcementResult*, and a [referrer](#) *referrer*:

1. Let *newCOOPEnforcementResult* be a new [opener policy enforcement result](#)<sup>p906</sup> with
  - [needs a browsing context group switch](#)<sup>p906</sup>
  - currentCOOPEnforcementResult*'s [needs a browsing context group switch](#)<sup>p906</sup>
  - [would need a browsing context group switch due to report-only](#)<sup>p906</sup>
  - currentCOOPEnforcementResult*'s [would need a browsing context group switch due to report-only](#)<sup>p906</sup>
  - [url](#)<sup>p906</sup>
  - responseURL*
  - [origin](#)<sup>p906</sup>
  - responseOrigin*
  - [opener policy](#)<sup>p906</sup>
  - responseCOOP*
  - [current context is navigation source](#)<sup>p906</sup>
  - true
2. Let *isInitialAboutBlank* be *browsingContext*'s [active document](#)<sup>p998</sup>'s [is initial about:blank](#)<sup>p131</sup>.

3. If *isInitialAboutBlank* is true and *browsingContext*'s [initial URL](#)<sup>p998</sup> is null, set *browsingContext*'s [initial URL](#)<sup>p998</sup> to *responseURL*.
4. If the result of [checking if COOP values require a browsing context group switch](#)<sup>p905</sup> given *isInitialAboutBlank*, *currentCOOPEnforcementResult*'s [opener policy](#)<sup>p906</sup>'s [value](#)<sup>p904</sup>, *currentCOOPEnforcementResult*'s [origin](#)<sup>p906</sup>, *responseCOOP*'s [value](#)<sup>p904</sup>, and *responseOrigin* is true, then:
  1. Set *newCOOPEnforcementResult*'s [needs a browsing context group switch](#)<sup>p906</sup> to true.
  2. If *browsingContext*'s [group](#)<sup>p1002</sup>'s [browsing context set](#)<sup>p1002</sup>'s [size](#) is greater than 1, then:
    1. [Queue a violation report for browsing context group switch when navigating to a COOP response](#)<sup>p909</sup> with *responseCOOP*, "enforce", *responseURL*, *currentCOOPEnforcementResult*'s [url](#)<sup>p906</sup>, *currentCOOPEnforcementResult*'s [origin](#)<sup>p906</sup>, *responseOrigin*, and *referrer*.
    2. [Queue a violation report for browsing context group switch when navigating away from a COOP response](#)<sup>p909</sup> with *currentCOOPEnforcementResult*'s [opener policy](#)<sup>p906</sup>, "enforce", *currentCOOPEnforcementResult*'s [url](#)<sup>p906</sup>, *responseURL*, *currentCOOPEnforcementResult*'s [origin](#)<sup>p906</sup>, *responseOrigin*, and *currentCOOPEnforcementResult*'s [current context is navigation source](#)<sup>p906</sup>.
5. If the result of [checking if enforcing report-only COOP would require a browsing context group switch](#)<sup>p906</sup> given *isInitialAboutBlank*, *responseOrigin*, *currentCOOPEnforcementResult*'s [origin](#)<sup>p906</sup>, *responseCOOP*, and *currentCOOPEnforcementResult*'s [opener policy](#)<sup>p906</sup>, is true, then:
  1. Set *result*'s [would need a browsing context group switch due to report-only](#)<sup>p906</sup> to true.
  2. If *browsingContext*'s [group](#)<sup>p1002</sup>'s [browsing context set](#)<sup>p1002</sup>'s [size](#) is greater than 1, then:
    1. [Queue a violation report for browsing context group switch when navigating to a COOP response](#)<sup>p909</sup> with *responseCOOP*, "reporting", *responseURL*, *currentCOOPEnforcementResult*'s [url](#)<sup>p906</sup>, *currentCOOPEnforcementResult*'s [origin](#)<sup>p906</sup>, *responseOrigin*, and *referrer*.
    2. [Queue a violation report for browsing context group switch when navigating away from a COOP response](#)<sup>p909</sup> with *currentCOOPEnforcementResult*'s [opener policy](#)<sup>p906</sup>, "reporting", *currentCOOPEnforcementResult*'s [url](#)<sup>p906</sup>, *responseURL*, *currentCOOPEnforcementResult*'s [origin](#)<sup>p906</sup>, *responseOrigin*, and *currentCOOPEnforcementResult*'s [current context is navigation source](#)<sup>p906</sup>.
6. Return *newCOOPEnforcementResult*.

To **obtain a browsing context to use for a navigation response**, given a [browsing context](#)<sup>p998</sup> *browsingContext*, a [sandboxing flag set](#)<sup>p914</sup> *sandboxFlags*, an [opener policy](#)<sup>p904</sup> *navigationCOOP*, and an [opener policy enforcement result](#)<sup>p906</sup> *coopEnforcementResult*:

1. If *browsingContext* is not a [top-level browsing context](#)<sup>p1001</sup>, then return *browsingContext*.
2. If *coopEnforcementResult*'s [needs a browsing context group switch](#)<sup>p906</sup> is false, then:
  1. If *coopEnforcementResult*'s [would need a browsing context group switch due to report-only](#)<sup>p906</sup> is true, set *browsingContext*'s [virtual browsing context group ID](#)<sup>p998</sup> to a new unique identifier.
  2. Return *browsingContext*.
3. Let *newBrowsingContext* be the first return value of [creating a new top-level browsing context and document](#)<sup>p1000</sup>.

#### Note

*In this case we are going to perform a browsing context group swap. *browsingContext* will not be used by the new [Document](#)<sup>p130</sup> that we are about to [create](#)<sup>p1056</sup>. If it is not used by other [Document](#)<sup>p130</sup>'s either (such as ones in the back/forward cache), then the user agent might [destroy it](#)<sup>p1003</sup> at this point.*

4. If *navigationCOOP*'s [value](#)<sup>p904</sup> is "same-origin-plus-COEP<sup>p903</sup>", then set *newBrowsingContext*'s [group](#)<sup>p1002</sup>'s [cross-origin isolation mode](#)<sup>p1002</sup> to either "logical<sup>p1002</sup>" or "concrete<sup>p1002</sup>". The choice of which is [implementation-defined](#).

#### Note

*It is difficult on some platforms to provide the security properties required by the [cross-origin isolated capability](#)<sup>p1076</sup>. "concrete<sup>p1002</sup>" grants access to it and "logical<sup>p1002</sup>" does not.*

5. If *sandboxFlags* is not empty, then:

1. **Assert:** `navigationCOOP`'s `value`<sup>p904</sup> is "`unsafe-none`"<sup>p983</sup>.
2. **Assert:** `newBrowsingContext`'s `popup sandboxing flag set`<sup>p917</sup> is empty.
3. Set `newBrowsingContext`'s `popup sandboxing flag set`<sup>p917</sup> to a `clone` of `sandboxFlags`.
6. Return `newBrowsingContext`.

### 7.1.3.3 Reporting <sup>p990</sup><sub>8</sub>

An **accessor-accessed relationship** is an enum that describes the relationship between two `browsing contexts`<sup>p998</sup> between which an access happened. It can take the following values:

#### **accessor is opener**

The accessor `browsing context`<sup>p998</sup> or one of its `ancestors`<sup>p1001</sup> is the `opener browsing context`<sup>p998</sup> of the accessed `browsing context`<sup>p998</sup>'s `top-level browsing context`<sup>p1001</sup>.

#### **accessor is openee**

The accessed `browsing context`<sup>p998</sup> or one of its `ancestors`<sup>p1001</sup> is the `opener browsing context`<sup>p998</sup> of the accessor `browsing context`<sup>p998</sup>'s `top-level browsing context`<sup>p1001</sup>.

#### **none**

There is no opener relationship between the accessor `browsing context`<sup>p998</sup>, the accessor `browsing context`<sup>p998</sup>, or any of their `ancestors`<sup>p1001</sup>.

To **check if an access between two browsing contexts should be reported**, given two `browsing contexts`<sup>p998</sup> `accessor` and `accessed`, a JavaScript property name `P`, and an `environment settings object`<sup>p1076</sup> `environment`:

1. If `P` is not a `cross-origin accessible window property name`<sup>p920</sup>, then return.
2. **Assert:** `accessor`'s `active document`<sup>p998</sup> and `accessed`'s `active document`<sup>p998</sup> are both `fully active`<sup>p1003</sup>.
3. Let `accessorTopDocument` be `accessor`'s `top-level browsing context`<sup>p1001</sup>'s `active document`<sup>p998</sup>.
4. Let `accessorInclusiveAncestorOrigins` be the list obtained by taking the `origin` of the `active document`<sup>p989</sup> of each of `accessor`'s `active document`<sup>p998</sup>'s `inclusive ancestor navigables`<sup>p994</sup>.
5. Let `accessedTopDocument` be `accessed`'s `top-level browsing context`<sup>p1001</sup>'s `active document`<sup>p998</sup>.
6. Let `accessedInclusiveAncestorOrigins` be the list obtained by taking the `origin` of the `active document`<sup>p989</sup> of each of `accessed`'s `active document`<sup>p998</sup>'s `inclusive ancestor navigables`<sup>p994</sup>.
7. If any of `accessorInclusiveAncestorOrigins` are not `same origin`<sup>p899</sup> with `accessorTopDocument`'s `origin`, or if any of `accessedInclusiveAncestorOrigins` are not `same origin`<sup>p899</sup> with `accessedTopDocument`'s `origin`, then return.

#### Note

*This avoids leaking information about cross-origin iframes to a top level frame with opener policy reporting.*

8. If `accessor`'s `top-level browsing context`<sup>p1001</sup>'s `virtual browsing context group ID`<sup>p998</sup> is `accessed`'s `top-level browsing context`<sup>p1001</sup>'s `virtual browsing context group ID`<sup>p998</sup>, then return.
9. Let `accessorAccessedRelationship` be a new `accessor-accessed relationship`<sup>p908</sup> with value `none`<sup>p908</sup>.
10. If `accessed`'s `top-level browsing context`<sup>p1001</sup>'s `opener browsing context`<sup>p998</sup> is `accessor` or is an `ancestor`<sup>p1001</sup> of `accessor`, then set `accessorAccessedRelationship` to `accessor is opener`<sup>p908</sup>.
11. If `accessor`'s `top-level browsing context`<sup>p1001</sup>'s `opener browsing context`<sup>p998</sup> is `accessed` or is an `ancestor`<sup>p1001</sup> of `accessed`, then set `accessorAccessedRelationship` to `accessor is openee`<sup>p908</sup>.
12. **Queue violation reports for accesses**<sup>p909</sup>, given `accessorAccessedRelationship`, `accessorTopDocument`'s `opener policy`<sup>p131</sup>, `accessedTopDocument`'s `opener policy`<sup>p131</sup>, `accessor`'s `active document`<sup>p998</sup>'s `URL`, `accessed`'s `active document`<sup>p998</sup>'s `URL`, `accessor`'s `top-level browsing context`<sup>p1001</sup>'s `initial URL`<sup>p998</sup>, `accessed`'s `top-level browsing context`<sup>p1001</sup>'s `initial URL`<sup>p998</sup>, `accessor`'s `active document`<sup>p998</sup>'s `origin`, `accessed`'s `active document`<sup>p998</sup>'s `origin`, `accessor`'s `top-level browsing context`<sup>p1001</sup>'s `opener origin at creation`<sup>p998</sup>, `accessed`'s `top-level browsing context`<sup>p1001</sup>'s `opener origin at creation`<sup>p998</sup>,

*accessorTopDocument*'s [referrer](#)<sup>p132</sup>, *accessedTopDocument*'s [referrer](#)<sup>p132</sup>, *P*, and *environment*.

To **sanitize a URL to send in a report** given a [URL](#) *url*:

1. Let *sanitizedURL* be a copy of *url*.
2. [Set the username](#) given *sanitizedURL* and the empty string.
3. [Set the password](#) given *sanitizedURL* and the empty string.
4. Return the [serialization](#) of *sanitizedURL* with [exclude fragment](#) set to true.

To **queue a violation report for browsing context group switch when navigating to a COOP response** given an [opener policy](#)<sup>p904</sup> *coop*, a string *disposition*, a [URL](#) *coopURL*, a [URL](#) *previousResponseURL*, two [origins](#)<sup>p898</sup> *coopOrigin* and *previousResponseOrigin*, and a [referrer](#) *referrer*:

1. If *coop*'s [reporting endpoint](#)<sup>p904</sup> is null, return.
2. Let *coopValue* be *coop*'s [value](#)<sup>p904</sup>.
3. If *disposition* is "reporting", then set *coopValue* to *coop*'s [report-only value](#)<sup>p904</sup>.
4. Let *serializedReferrer* be an empty string.
5. If *referrer* is a [URL](#), set *serializedReferrer* to the [serialization](#) of *referrer*.
6. Let *body* be a new object containing the following properties:

key	value
<i>disposition</i>	<i>disposition</i>
<i>effectivePolicy</i>	<i>coopValue</i>
<i>previousResponseURL</i>	If <i>coopOrigin</i> and <i>previousResponseOrigin</i> are <a href="#">same origin</a> <sup>p899</sup> this is the <a href="#">sanitization</a> <sup>p909</sup> of <i>previousResponseURL</i> , null otherwise.
<i>referrer</i>	<i>serializedReferrer</i>
<i>type</i>	"navigation-to-response"

7. [Queue](#) *body* as "coop" for *coop*'s [reporting endpoint](#)<sup>p904</sup> with *coopURL*.

To **queue a violation report for browsing context group switch when navigating away from a COOP response** given an [opener policy](#)<sup>p904</sup> *coop*, a string *disposition*, a [URL](#) *coopURL*, a [URL](#) *nextResponseURL*, two [origins](#)<sup>p898</sup> *coopOrigin* and *nextResponseOrigin*, and a boolean *isCOOPResponseNavigationSource*:

1. If *coop*'s [reporting endpoint](#)<sup>p904</sup> is null, return.
2. Let *coopValue* be *coop*'s [value](#)<sup>p904</sup>.
3. If *disposition* is "reporting", then set *coopValue* to *coop*'s [report-only value](#)<sup>p904</sup>.
4. Let *body* be a new object containing the following properties:

key	value
<i>disposition</i>	<i>disposition</i>
<i>effectivePolicy</i>	<i>coopValue</i>
<i>nextResponseURL</i>	If <i>coopOrigin</i> and <i>nextResponseOrigin</i> are <a href="#">same origin</a> <sup>p899</sup> or <i>isCOOPResponseNavigationSource</i> is true, this is the <a href="#">sanitization</a> <sup>p909</sup> of <i>previousResponseURL</i> , null otherwise.
<i>type</i>	"navigation-from-response"

5. [Queue](#) *body* as "coop" for *coop*'s [reporting endpoint](#)<sup>p904</sup> with *coopURL*.

To **queue violation reports for accesses**, given an [accessor-accessed relationship](#)<sup>p908</sup> *accessorAccessedRelationship*, two [opener policies](#)<sup>p904</sup> *accessorCOOP* and *accessedCOOP*, four [URLs](#) *accessorURL*, *accessedURL*, *accessorInitialURL*, *accessedInitialURL*, four [origins](#)<sup>p898</sup> *accessorOrigin*, *accessedOrigin*, *accessorCreatorOrigin* and *accessedCreatorOrigin*, two [referrers](#)<sup>p132</sup> *accessorReferrer* and *accessedReferrer*, a string *propertyName*, and an [environment settings object](#)<sup>p1076</sup> *environment*:

1. If *coop*'s [reporting endpoint](#)<sup>p904</sup> is null, return.
2. Let *coopValue* be *coop*'s [value](#)<sup>p904</sup>.

3. If *disposition* is "reporting", then set *coopValue* to *coop*'s [report-only value](#)<sup>p904</sup>.
4. If *accessorAccessedRelationship* is [accessor is opener](#)<sup>p908</sup>:
  1. [Queue a violation report for access to an opened window](#)<sup>p910</sup>, given *accessorCOOP*, *accessorURL*, *accessedURL*, *accessedInitialURL*, *accessorOrigin*, *accessedOrigin*, *accessedCreatorOrigin*, *propertyName*, and *environment*.
  2. [Queue a violation report for access from the opener](#)<sup>p911</sup>, given *accessedCOOP*, *accessedURL*, *accessorURL*, *accessedOrigin*, *accessorOrigin*, *propertyName*, and *accessedReferrer*.
5. Otherwise, if *accessorAccessedRelationship* is [accessor is openee](#)<sup>p908</sup>:
  1. [Queue a violation report for access to the opener](#)<sup>p910</sup>, given *accessorCOOP*, *accessorURL*, *accessedURL*, *accessorOrigin*, *accessedOrigin*, *propertyName*, *accessorReferrer*, and *environment*.
  2. [Queue a violation report for access from an opened window](#)<sup>p911</sup>, given *accessedCOOP*, *accessedURL*, *accessorURL*, *accessorInitialURL*, *accessedOrigin*, *accessorOrigin*, *accessorCreatorOrigin*, and *propertyName*.
6. Otherwise:
  1. [Queue a violation report for access to another window](#)<sup>p910</sup>, given *accessorCOOP*, *accessorURL*, *accessedURL*, *accessorOrigin*, *accessedOrigin*, *propertyName*, and *environment*.
  2. [Queue a violation report for access from another window](#)<sup>p912</sup>, given *accessedCOOP*, *accessedURL*, *accessorURL*, *accessedOrigin*, *accessorOrigin*, and *propertyName*.

To **queue a violation report for access to the opener**, given an [opener policy](#)<sup>p904</sup> *coop*, two [URLs](#) *coopURL* and *openerURL*, two [origins](#)<sup>p898</sup> *coopOrigin* and *openerOrigin*, a string *propertyName*, a [referrer](#) *referrer*, and an [environment settings object](#)<sup>p1076</sup> *environment*:

1. Let *sourceFile*, *lineNumber* and *columnNumber* be the relevant script URL and problematic position which triggered this report.
2. Let *serializedReferrer* be an empty string.
3. If *referrer* is a [URL](#), set *serializedReferrer* to the [serialization](#) of *referrer*.
4. Let *body* be a new object containing the following properties:

key	value
<i>disposition</i>	"reporting"
<i>effectivePolicy</i>	<i>coop</i> 's <a href="#">report-only value</a> <sup>p904</sup>
<i>property</i>	<i>propertyName</i>
<i>openerURL</i>	If <i>coopOrigin</i> and <i>openerOrigin</i> are <a href="#">same origin</a> <sup>p899</sup> , this is the <a href="#">sanitization</a> <sup>p909</sup> of <i>openerURL</i> , null otherwise.
<i>referrer</i>	<i>serializedReferrer</i>
<i>sourceFile</i>	<i>sourceFile</i>
<i>lineNumber</i>	<i>lineNumber</i>
<i>columnNumber</i>	<i>columnNumber</i>
<i>type</i>	"access-to-opener"

5. [Queue](#) *body* as "coop" for *coop*'s [reporting endpoint](#)<sup>p904</sup> with *coopURL* and *environment*.

To **queue a violation report for access to an opened window**, given an [opener policy](#)<sup>p904</sup> *coop*, three [URLs](#) *coopURL*, *openedWindowURL* and *initialWindowURL*, three [origins](#)<sup>p898</sup> *coopOrigin*, *openedWindowOrigin*, and *openerInitialOrigin*, a string *propertyName*, and an [environment settings object](#)<sup>p1076</sup> *environment*:

1. Let *sourceFile*, *lineNumber* and *columnNumber* be the relevant script URL and problematic position which triggered this report.
2. Let *body* be a new object containing the following properties:

key	value
<i>disposition</i>	"reporting"
<i>effectivePolicy</i>	<i>coop</i> 's <a href="#">report-only value</a> <sup>p904</sup>
<i>property</i>	<i>propertyName</i>
<i>openedWindowURL</i>	If <i>coopOrigin</i> and <i>openedWindowOrigin</i> are <a href="#">same origin</a> <sup>p899</sup> , this is the <a href="#">sanitization</a> <sup>p909</sup> of <i>openedWindowURL</i> , null otherwise.

key	value
openedWindowInitialURL	If <i>coopOrigin</i> and <i>openerInitialOrigin</i> are <a href="#">same origin</a> <sup>p899</sup> , this is the <a href="#">sanitization</a> <sup>p909</sup> of <i>initialWindowURL</i> , null otherwise.
sourceFile	<i>sourceFile</i>
lineNumber	<i>lineNumber</i>
columnNumber	<i>columnNumber</i>
type	"access-to-opener"

3. **Queue** *body* as "coop" for *coop*'s [reporting endpoint](#)<sup>p904</sup> with *coopURL* and *environment*.

To **queue a violation report for access to another window**, given an [opener policy](#)<sup>p904</sup> *coop*, two [URLs](#) *coopURL* and *otherURL*, two [origins](#)<sup>p898</sup> *coopOrigin* and *otherOrigin*, a string *propertyName*, and an [environment settings object](#)<sup>p1076</sup> *environment*:

1. Let *sourceFile*, *lineNumber* and *columnNumber* be the relevant script URL and problematic position which triggered this report.
2. Let *body* be a new object containing the following properties:

key	value
disposition	"reporting"
effectivePolicy	<i>coop</i> 's <a href="#">report-only value</a> <sup>p904</sup>
property	<i>propertyName</i>
otherURL	If <i>coopOrigin</i> and <i>otherOrigin</i> are <a href="#">same origin</a> <sup>p899</sup> , this is the <a href="#">sanitization</a> <sup>p909</sup> of <i>otherURL</i> , null otherwise.
sourceFile	<i>sourceFile</i>
lineNumber	<i>lineNumber</i>
columnNumber	<i>columnNumber</i>
type	"access-to-opener"

3. **Queue** *body* as "coop" for *coop*'s [reporting endpoint](#)<sup>p904</sup> with *coopURL* and *environment*.

To **queue a violation report for access from the opener**, given an [opener policy](#)<sup>p904</sup> *coop*, two [URLs](#) *coopURL* and *openerURL*, two [origins](#)<sup>p898</sup> *coopOrigin* and *openerOrigin*, a string *propertyName*, and a [referrer](#) *referrer*:

1. If *coop*'s [reporting endpoint](#)<sup>p904</sup> is null, return.
2. Let *serializedReferrer* be an empty string.
3. If *referrer* is a [URL](#), set *serializedReferrer* to the [serialization](#) of *referrer*.
4. Let *body* be a new object containing the following properties:

key	value
disposition	"reporting"
effectivePolicy	<i>coop</i> 's <a href="#">report-only value</a> <sup>p904</sup>
property	<i>propertyName</i>
openerURL	If <i>coopOrigin</i> and <i>openerOrigin</i> are <a href="#">same origin</a> <sup>p899</sup> , this is the <a href="#">sanitization</a> <sup>p909</sup> of <i>openerURL</i> , null otherwise.
referrer	<i>serializedReferrer</i>
type	"access-to-opener"

5. **Queue** *body* as "coop" for *coop*'s [reporting endpoint](#)<sup>p904</sup> with *coopURL*.

To **queue a violation report for access from an opened window**, given an [opener policy](#)<sup>p904</sup> *coop*, three [URLs](#) *coopURL*, *openedWindowURL* and *initialWindowURL*, three [origins](#)<sup>p898</sup> *coopOrigin*, *openedWindowOrigin*, and *openerInitialOrigin*, and a string *propertyName*:

1. If *coop*'s [reporting endpoint](#)<sup>p904</sup> is null, return.
2. Let *body* be a new object containing the following properties:

key	value
disposition	"reporting"
effectivePolicy	<i>coopValue</i>
property	<i>coop</i> 's <a href="#">report-only value</a> <sup>p904</sup>
openedWindowURL	If <i>coopOrigin</i> and <i>openedWindowOrigin</i> are <a href="#">same origin</a> <sup>p899</sup> , this is the <a href="#">sanitization</a> <sup>p909</sup> of <i>openedWindowURL</i> , null otherwise.

key	value
openedWindowInitialURL	If <i>coopOrigin</i> and <i>openerInitialOrigin</i> are <a href="#">same origin</a> <sup>p899</sup> , this is the <a href="#">sanitization</a> <sup>p909</sup> of <i>initialWindowURL</i> , null otherwise.
type	"access-to-opener"

3. **Queue** *body* as "coop" for *coop*'s [reporting endpoint](#)<sup>p904</sup> with *coopURL*.

To **queue a violation report for access from another window**, given an [opener policy](#)<sup>p904</sup> *coop*, two [URLs](#) *coopURL* and *otherURL*, two [origins](#)<sup>p898</sup> *coopOrigin* and *otherOrigin*, and a string *propertyName*:

1. If *coop*'s [reporting endpoint](#)<sup>p904</sup> is null, return.
2. Let *body* be a new object containing the following properties:

key	value
disposition	"reporting"
effectivePolicy	<i>coop</i> 's <a href="#">report-only value</a> <sup>p904</sup>
property	<i>propertyName</i>
otherURL	If <i>coopOrigin</i> and <i>otherOrigin</i> are <a href="#">same origin</a> <sup>p899</sup> , this is the <a href="#">sanitization</a> <sup>p909</sup> of <i>otherURL</i> , null otherwise.
type	access-to-opener

3. **Queue** *body* as "coop" for *coop*'s [reporting endpoint](#)<sup>p904</sup> with *coopURL*.

### 7.1.4 Cross-origin embedder policies <sup>p912</sup>

An **embedder policy value** is one of three strings that controls the fetching of cross-origin resources without explicit permission from resource owners.

#### "unsafe-none"

This is the default value. When this value is used, cross-origin resources can be fetched without giving explicit permission through the [CORS protocol](#) or the [`Cross-Origin-Resource-Policy`](#) header.

#### "require-corp"

When this value is used, fetching cross-origin resources requires the server's explicit permission through the [CORS protocol](#) or the [`Cross-Origin-Resource-Policy`](#) header.

#### "credentialless"

When this value is used, fetching cross-origin no-CORS resources omits credentials. In exchange, an explicit [`Cross-Origin-Resource-Policy`](#) header is not required. Other requests sent with credentials require the server's explicit permission through the [CORS protocol](#) or the [`Cross-Origin-Resource-Policy`](#) header.

#### ⚠Warning!

**Before supporting "credentialless"<sup>p912</sup>, implementers are strongly encouraged to support both:**

- [Private Network Access](#)
- [Opaque Response Blocking](#)

**Otherwise, it would allow attackers to leverage the client's network position to read non public resources, using the [cross-origin isolated capability](#)<sup>p1076</sup>.**

An [embedder policy value](#)<sup>p912</sup> is **compatible with cross-origin isolation** if it is "credentialless"<sup>p912</sup> or "require-corp"<sup>p912</sup>.

An **embedder policy** consists of:

- A **value**, which is an [embedder policy value](#)<sup>p912</sup>, initially "unsafe-none"<sup>p912</sup>.
- A **reporting endpoint** string, initially the empty string.
- A **report only value**, which is an [embedder policy value](#)<sup>p912</sup>, initially "unsafe-none"<sup>p912</sup>.
- A **report only reporting endpoint** string, initially the empty string.

The "coop" **report type** is a [report type](#) whose value is "coop". It is [visible to ReportingObservers](#).

#### 7.1.4.1 The headers §<sup>p91</sup><sub>3</sub>

The ``Cross-Origin-Embedder-Policy`` and ``Cross-Origin-Embedder-Policy-Report-Only`` HTTP response headers allow a server to declare an [embedder policy](#)<sup>p912</sup> for an [environment settings object](#)<sup>p1076</sup>. These headers are [structured headers](#) whose values must be [token](#). [\[STRUCTURED-FIELDS\]](#)<sup>p1482</sup>

The valid [token](#) values are the [embedder policy values](#)<sup>p912</sup>. The token may also have attached [parameters](#); of these, the `"report-to"` parameter can have a [valid URL string](#) identifying an appropriate reporting endpoint. [\[REPORTING\]](#)<sup>p1480</sup>

#### Note

The [processing model](#)<sup>p913</sup> fails open (by defaulting to `"unsafe-none"`<sup>p912</sup>) in the presence of a header that cannot be parsed as a token. This includes inadvertent lists created by combining multiple instances of the ``Cross-Origin-Embedder-Policy``<sup>p913</sup> header present in a given response:

<code>`Cross-Origin-Embedder-Policy`</code> <sup>p913</sup>	Final embedder policy value <sup>p912</sup>
No header delivered	<code>"unsafe-none"</code> <sup>p912</sup>
<code>`require-corp`</code>	<code>"require-corp"</code> <sup>p912</sup>
<code>`unknown-value`</code>	<code>"unsafe-none"</code> <sup>p912</sup>
<code>`require-corp, unknown-value`</code>	<code>"unsafe-none"</code> <sup>p912</sup>
<code>`unknown-value, unknown-value`</code>	<code>"unsafe-none"</code> <sup>p912</sup>
<code>`unknown-value, require-corp`</code>	<code>"unsafe-none"</code> <sup>p912</sup>
<code>`require-corp, require-corp`</code>	<code>"unsafe-none"</code> <sup>p912</sup>

(The same applies to ``Cross-Origin-Embedder-Policy-Report-Only``<sup>p913</sup>.)

To **obtain an embedder policy** from a [response](#) response and an [environment](#)<sup>p1075</sup> environment:

1. Let *policy* be a new [embedder policy](#)<sup>p912</sup>.
2. If *environment* is a [non-secure context](#)<sup>p1084</sup>, then return *policy*.
3. Let *parsedItem* be the result of [getting a structured field value](#) with ``Cross-Origin-Embedder-Policy``<sup>p913</sup> and "item" from *response*'s [header list](#).
4. If *parsedItem* is non-null and *parsedItem*[0] is [compatible with cross-origin isolation](#)<sup>p912</sup>:
  1. Set *policy*'s [value](#)<sup>p912</sup> to *parsedItem*[0].
  2. If *parsedItem*[1][`"report-to"`<sup>p913</sup>] exists, then set *policy*'s [endpoint](#)<sup>p912</sup> to *parsedItem*[1][`"report-to"`<sup>p913</sup>].
5. Set *parsedItem* to the result of [getting a structured field value](#) with ``Cross-Origin-Embedder-Policy-Report-Only``<sup>p913</sup> and "item" from *response*'s [header list](#).
6. If *parsedItem* is non-null and *parsedItem*[0] is [compatible with cross-origin isolation](#)<sup>p912</sup>:
  1. Set *policy*'s [report only value](#)<sup>p912</sup> to *parsedItem*[0].
  2. If *parsedItem*[1][`"report-to"`<sup>p913</sup>] exists, then set *policy*'s [endpoint](#)<sup>p912</sup> to *parsedItem*[1][`"report-to"`<sup>p913</sup>].
7. Return *policy*.

#### 7.1.4.2 Embedder policy checks §<sup>p91</sup><sub>3</sub>

To **check a navigation response's adherence to its embedder policy** given a [response](#) response, a [navigable](#)<sup>p989</sup> navigable, and an [embedder policy](#)<sup>p912</sup> *responsePolicy*:

1. If *navigable* is not a [child navigable](#)<sup>p992</sup>, then return true.
2. Let *parentPolicy* be *navigable*'s [container document](#)<sup>p992</sup>'s [policy container](#)<sup>p131</sup>'s [embedder policy](#)<sup>p917</sup>.
3. If *parentPolicy*'s [report-only value](#)<sup>p912</sup> is [compatible with cross-origin isolation](#)<sup>p912</sup> and *responsePolicy*'s [value](#)<sup>p912</sup> is not, then [queue a cross-origin embedder policy inheritance violation](#)<sup>p914</sup> with *response*, "navigation", *parentPolicy*'s [report only](#)

[reporting endpoint](#)<sup>p912</sup>, "reporting", and *navigable*'s [container document](#)<sup>p992</sup>'s [relevant settings object](#)<sup>p1083</sup>.

4. If *parentPolicy*'s [value](#)<sup>p912</sup> is not [compatible with cross-origin isolation](#)<sup>p912</sup> or *responsePolicy*'s [value](#)<sup>p912</sup> is [compatible with cross-origin isolation](#)<sup>p912</sup>, then return true.
5. [Queue a cross-origin embedder policy inheritance violation](#)<sup>p914</sup> with *response*, "navigation", *parentPolicy*'s [reporting endpoint](#)<sup>p912</sup>, "enforce", and *navigable*'s [container document](#)<sup>p992</sup>'s [relevant settings object](#)<sup>p1083</sup>.
6. Return false.

To **check a global object's embedder policy** given a [WorkerGlobalScope](#)<sup>p1228</sup> *workerGlobalScope*, an [environment settings object](#)<sup>p1076</sup> *owner*, and a [response](#) *response*:

1. If *workerGlobalScope* is not a [DedicatedWorkerGlobalScope](#)<sup>p1238</sup> object, then return true.
2. Let *policy* be *workerGlobalScope*'s [embedder policy](#)<sup>p1229</sup>.
3. Let *ownerPolicy* be *owner*'s [policy container](#)<sup>p1076</sup>'s [embedder policy](#)<sup>p917</sup>.
4. If *ownerPolicy*'s [report-only value](#)<sup>p912</sup> is [compatible with cross-origin isolation](#)<sup>p912</sup> and *policy*'s [value](#)<sup>p912</sup> is not, then [queue a cross-origin embedder policy inheritance violation](#)<sup>p914</sup> with *response*, "worker initialization", *ownerPolicy*'s [report only reporting endpoint](#)<sup>p912</sup>, "reporting", and *owner*.
5. If *ownerPolicy*'s [value](#)<sup>p912</sup> is not [compatible with cross-origin isolation](#)<sup>p912</sup> or *policy*'s [value](#)<sup>p912</sup> is [compatible with cross-origin isolation](#)<sup>p912</sup>, then return true.
6. [Queue a cross-origin embedder policy inheritance violation](#)<sup>p914</sup> with *response*, "worker initialization", *ownerPolicy*'s [reporting endpoint](#)<sup>p912</sup>, "enforce", and *owner*.
7. Return false.

To **queue a cross-origin embedder policy inheritance violation** given a [response](#) *response*, a string *type*, a string *endpoint*, a string *disposition*, and an [environment settings object](#)<sup>p1076</sup> *settings*:

1. Let *serialized* be the result of [serializing a response URL for reporting](#) with *response*.
2. Let *body* be a new object containing the following properties:

key	value
type	<i>type</i>
blockedURL	<i>serialized</i>
disposition	<i>disposition</i>

3. [Queue](#) *body* as the ["coep" report type](#)<sup>p912</sup> for *endpoint* on *settings*.

### 7.1.5 Sandboxing <sup>p91</sup><sub>4</sub>

A **sandboxing flag set** is a set of zero or more of the following flags, which are used to restrict the abilities that potentially untrusted resources have:

#### The *sandboxed navigation browsing context* flag

This flag [prevents content from navigating browsing contexts other than the sandboxed browsing context itself](#)<sup>p1015</sup> (or browsing contexts further nested inside it), [auxiliary browsing contexts](#)<sup>p999</sup> (which are protected by the [sandboxed auxiliary navigation browsing context flag](#)<sup>p915</sup> defined next), and the [top-level browsing context](#)<sup>p1001</sup> (which is protected by the [sandboxed top-level navigation without user activation browsing context flag](#)<sup>p915</sup> and [sandboxed top-level navigation with user activation browsing context flag](#)<sup>p915</sup> defined below).

If the [sandboxed auxiliary navigation browsing context flag](#)<sup>p915</sup> is not set, then in certain cases the restrictions nonetheless allow popups (new [top-level browsing contexts](#)<sup>p1001</sup>) to be opened. These [browsing contexts](#)<sup>p998</sup> always have **one permitted sandboxed navigator**, set when the browsing context is created, which allows the [browsing context](#)<sup>p998</sup> that created them to actually navigate them. (Otherwise, the [sandboxed navigation browsing context flag](#)<sup>p914</sup> would prevent them from being navigated even if they were opened.)

### The **sandboxed auxiliary navigation browsing context flag**

This flag [prevents content from creating new auxiliary browsing contexts](#)<sup>p997</sup>, e.g. using the [target](#)<sup>p303</sup> attribute or the [window.open\(\)](#)<sup>p926</sup> method.

### The **sandboxed top-level navigation without user activation browsing context flag**

This flag [prevents content from navigating their top-level browsing context](#)<sup>p1015</sup> and [prevents content from closing their top-level browsing context](#)<sup>p928</sup>. It is consulted only when the sandboxed browsing context's [active window](#)<sup>p998</sup> does not have [transient activation](#)<sup>p830</sup>.

When the [sandboxed top-level navigation without user activation browsing context flag](#)<sup>p915</sup> is *not* set, content can navigate its [top-level browsing context](#)<sup>p1001</sup>, but other [browsing contexts](#)<sup>p998</sup> are still protected by the [sandboxed navigation browsing context flag](#)<sup>p914</sup> and possibly the [sandboxed auxiliary navigation browsing context flag](#)<sup>p915</sup>.

### The **sandboxed top-level navigation with user activation browsing context flag**

This flag [prevents content from navigating their top-level browsing context](#)<sup>p1015</sup> and [prevents content from closing their top-level browsing context](#)<sup>p928</sup>. It is consulted only when the sandboxed browsing context's [active window](#)<sup>p998</sup> has [transient activation](#)<sup>p830</sup>.

As with the [sandboxed top-level navigation without user activation browsing context flag](#)<sup>p915</sup>, this flag only affects the [top-level browsing context](#)<sup>p1001</sup>; if it is not set, other [browsing contexts](#)<sup>p998</sup> might still be protected by other flags.

### The **sandboxed origin browsing context flag**

This flag [forces content into an opaque origin](#)<sup>p1001</sup>, thus preventing it from accessing other content from the same [origin](#)<sup>p898</sup>.

This flag also [prevents script from reading from or writing to the document.cookie IDL attribute](#)<sup>p132</sup>, and blocks access to [localStorage](#)<sup>p1255</sup>.

### The **sandboxed forms browsing context flag**

This flag [blocks form submission](#)<sup>p629</sup>.

### The **sandboxed pointer lock browsing context flag**

This flag disables the Pointer Lock API. [\[POINTERLOCK\]](#)<sup>p1481</sup>

### The **sandboxed scripts browsing context flag**

This flag [blocks script execution](#)<sup>p1083</sup>.

### The **sandboxed automatic features browsing context flag**

This flag blocks features that trigger automatically, such as [automatically playing a video](#)<sup>p435</sup> or [automatically focusing a form control](#)<sup>p848</sup>.

### The **sandboxed document.domain browsing context flag**

This flag prevents content from using the [document.domain](#)<sup>p901</sup> setter.

### The **sandbox propagates to auxiliary browsing contexts flag**

This flag prevents content from escaping the sandbox by ensuring that any [auxiliary browsing context](#)<sup>p999</sup> it creates inherits the content's [active sandboxing flag set](#)<sup>p917</sup>.

### The **sandboxed modals flag**

This flag prevents content from using any of the following features to produce modal dialogs:

- [window.alert\(\)](#)<sup>p1167</sup>
- [window.confirm\(\)](#)<sup>p1168</sup>
- [window.print\(\)](#)<sup>p1169</sup>
- [window.prompt\(\)](#)<sup>p1168</sup>
- the [beforeunload](#)<sup>p1471</sup> event

### The **sandboxed orientation lock browsing context flag**

This flag disables the ability to lock the screen orientation. [\[SCREENORIENTATION\]](#)<sup>p1482</sup>

### The **sandboxed presentation browsing context flag**

This flag disables the Presentation API. [\[PRESENTATION\]](#)<sup>p1481</sup>

### The **sandboxed downloads browsing context flag**

This flag prevents content from initiating or instantiating downloads, whether through [downloading hyperlinks](#)<sup>p310</sup> or through [navigation](#)<sup>p1031</sup> that gets handled [as a download](#)<sup>p311</sup>.

### The **sandboxed custom protocols navigation browsing context flag**

This flag prevents navigations toward non [fetch schemes](#) from being [handed off to external software](#)<sup>p1024</sup>.

When the user agent is to **parse a sandboxing directive**, given a string *input*, a [sandboxing flag set](#)<sup>p914</sup> *output*, it must run the following steps:

1. [Split input on ASCII whitespace](#), to obtain *tokens*.
2. Let *output* be empty.
3. Add the following flags to *output*:
  - The [sandboxed navigation browsing context flag](#)<sup>p914</sup>.
  - The [sandboxed auxiliary navigation browsing context flag](#)<sup>p915</sup>, unless *tokens* contains the **allow-popups** keyword.
  - The [sandboxed top-level navigation without user activation browsing context flag](#)<sup>p915</sup>, unless *tokens* contains the **allow-top-navigation** keyword.
  - The [sandboxed top-level navigation with user activation browsing context flag](#)<sup>p915</sup>, unless *tokens* contains either the **allow-top-navigation-by-user-activation** keyword or the [allow-top-navigation](#)<sup>p916</sup> keyword.

#### Note

*This means that if the [allow-top-navigation](#)<sup>p916</sup> is present, the [allow-top-navigation-by-user-activation](#)<sup>p916</sup> keyword will have no effect. For this reason, specifying both is a document conformance error.*

- The [sandboxed origin browsing context flag](#)<sup>p915</sup>, unless the *tokens* contains the **allow-same-origin** keyword.

#### Note

*The [allow-same-origin](#)<sup>p916</sup> keyword is intended for two cases.*

*First, it can be used to allow content from the same site to be sandboxed to disable scripting, while still allowing access to the DOM of the sandboxed content.*

*Second, it can be used to embed content from a third-party site, sandboxed to prevent that site from opening popups, etc, without preventing the embedded page from communicating back to its originating site, using the database APIs to store data, etc.*

- The [sandboxed forms browsing context flag](#)<sup>p915</sup>, unless *tokens* contains the **allow-forms** keyword.
- The [sandboxed pointer lock browsing context flag](#)<sup>p915</sup>, unless *tokens* contains the **allow-pointer-lock** keyword.
- The [sandboxed scripts browsing context flag](#)<sup>p915</sup>, unless *tokens* contains the **allow-scripts** keyword.
- The [sandboxed automatic features browsing context flag](#)<sup>p915</sup>, unless *tokens* contains the [allow-scripts](#)<sup>p916</sup> keyword (defined above).

#### Note

*This flag is relaxed by the same keyword as *scripts*, because when *scripts* are enabled these features are trivially possible anyway, and it would be unfortunate to force authors to use *script* to do them when sandboxed rather than allowing them to use the declarative features.*

- The [sandboxed document.domain browsing context flag](#)<sup>p915</sup>.
- The [sandbox propagates to auxiliary browsing contexts flag](#)<sup>p915</sup>, unless *tokens* contains the **allow-popups-to-escape-sandbox** keyword.
- The [sandboxed modals flag](#)<sup>p915</sup>, unless *tokens* contains the **allow-modals** keyword.
- The [sandboxed orientation lock browsing context flag](#)<sup>p915</sup>, unless *tokens* contains the **allow-orientation-lock** keyword.

- The [sandboxed presentation browsing context flag](#)<sup>p915</sup>, unless *tokens* contains the **allow-presentation** keyword.
- The [sandboxed downloads browsing context flag](#)<sup>p916</sup>, unless *tokens* contains the **allow-downloads** keyword.
- The [sandboxed custom protocols navigation browsing context flag](#)<sup>p916</sup>, unless *tokens* contains either the **allow-top-navigation-to-custom-protocols** keyword, the [allow-popups](#)<sup>p916</sup> keyword, or the [allow-top-navigation](#)<sup>p916</sup> keyword.

Every [top-level browsing context](#)<sup>p1001</sup> has a **popup sandboxing flag set**, which is a [sandboxing flag set](#)<sup>p914</sup>. When a [browsing context](#)<sup>p998</sup> is created, its [popup sandboxing flag set](#)<sup>p917</sup> must be empty. It is populated by [the rules for choosing a navigable](#)<sup>p997</sup> and the [obtain a browsing context to use for a navigation response](#)<sup>p907</sup> algorithm.

Every [iframe](#)<sup>p390</sup> element has an **iframe sandboxing flag set**, which is a [sandboxing flag set](#)<sup>p914</sup>. Which flags in an [iframe sandboxing flag set](#)<sup>p917</sup> are set at any particular time is determined by the [iframe](#)<sup>p390</sup> element's [sandbox](#)<sup>p395</sup> attribute.

Every [Document](#)<sup>p130</sup> has an **active sandboxing flag set**, which is a [sandboxing flag set](#)<sup>p914</sup>. When the [Document](#)<sup>p130</sup> is created, its [active sandboxing flag set](#)<sup>p917</sup> must be empty. It is populated by the [navigation algorithm](#)<sup>p1014</sup>.

Every [CSP list](#) *cspList* has **CSP-derived sandboxing flags**, which is a [sandboxing flag set](#)<sup>p914</sup>. It is the return value of the following algorithm:

1. Let *directives* be an empty [ordered set](#).
2. **For each** *policy* in *cspList*:
  1. If *policy*'s [disposition](#) is not "enforce", then [continue](#).
  2. If *policy*'s [directive set contains](#) a [directive](#) whose name is "sandbox", then [append](#) that directive to *directives*.
3. If *directives* is empty, then return an empty [sandboxing flag set](#)<sup>p914</sup>.
4. Let *directive* be *directives*[*directives*'s [size](#) – 1].
5. Return the result of [parsing the sandboxing directive](#)<sup>p916</sup> *directive*.

To **determine the creation sandboxing flags** for a [browsing context](#)<sup>p999</sup> *browsing context*, given null or an element *embedder*, return the [union](#) of the flags that are present in the following [sandboxing flag sets](#)<sup>p914</sup>:

- If *embedder* is null, then: the flags set on *browsing context*'s [popup sandboxing flag set](#)<sup>p917</sup>.
- If *embedder* is an element, then: the flags set on *embedder*'s [iframe sandboxing flag set](#)<sup>p917</sup>.
- If *embedder* is an element, then: the flags set on *embedder*'s [node document](#)'s [active sandboxing flag set](#)<sup>p917</sup>.

### 7.1.6 Policy containers <sup>§ p91</sup><sub>7</sub>

A **policy container** is a [struct](#) containing policies that apply to a [Document](#)<sup>p130</sup>, a [WorkerGlobalScope](#)<sup>p1228</sup>, or a [WorkletGlobalScope](#)<sup>p1245</sup>. It has the following [items](#):

- A **CSP list**, which is a [CSP list](#). It is initially empty.
- An **embedder policy**, which is an [embedder policy](#)<sup>p912</sup>. It is initially a new [embedder policy](#)<sup>p912</sup>.
- A **referrer policy**, which is a [referrer policy](#). It is initially the [default referrer policy](#).

Move other policies into the policy container.

To **clone a policy container** given a [policy container](#)<sup>p917</sup> *policyContainer*:

1. Let *clone* be a new [policy container](#)<sup>p917</sup>.
2. **For each** *policy* in *policyContainer*'s [CSP list](#)<sup>p917</sup>, [append](#) a copy of *policy* into *clone*'s [CSP list](#)<sup>p917</sup>.

3. Set *clone*'s [embedder policy](#)<sup>p917</sup> to a copy of *policyContainer*'s [embedder policy](#)<sup>p917</sup>.
4. Set *clone*'s [referrer policy](#)<sup>p917</sup> to *policyContainer*'s [referrer policy](#)<sup>p917</sup>.
5. Return *clone*.

To determine whether a [URL](#) *url* **requires storing the policy container in history**:

1. If *url*'s [scheme](#) is "blob", then return false.
2. If *url* [is local](#), then return true.
3. Return false.

To **create a policy container from a fetch response** given a [response](#) *response* and an [environment](#)<sup>p1075</sup>-or-null *environment*:

1. If *response*'s [URL](#)'s [scheme](#) is "blob", then return a [clone](#)<sup>p917</sup> of *response*'s [URL](#)'s [blob URL entry](#)'s [environment](#)'s [policy container](#)<sup>p917</sup>.
2. Let *result* be a new [policy container](#)<sup>p917</sup>.
3. Set *result*'s [CSP list](#)<sup>p917</sup> to the result of [parsing a response's Content Security Policies](#) given *response*.
4. If *environment* is non-null, then set *result*'s [embedder policy](#)<sup>p917</sup> to the result of [obtaining an embedder policy](#)<sup>p913</sup> given *response* and *environment*. Otherwise, set it to ["unsafe-none"](#)<sup>p912</sup>.
5. Set *result*'s [referrer policy](#)<sup>p917</sup> to the result of [parsing the `Referrer-Policy` header](#) given *response*. [\[REFERRERPOLICY\]](#)<sup>p1481</sup>
6. Return *result*.

To **determine navigation params policy container** given a [URL](#) *responseURL* and four [policy container](#)<sup>p917</sup>-or-nulls *historyPolicyContainer*, *initiatorPolicyContainer*, *parentPolicyContainer*, and *responsePolicyContainer*:

1. If *historyPolicyContainer* is not null, then:
  1. [Assert](#): *responseURL* [requires storing the policy container in history](#)<sup>p918</sup>.
  2. Return a [clone](#)<sup>p917</sup> of *historyPolicyContainer*.
2. If *responseURL* is [about:srcdoc](#)<sup>p96</sup>, then:
  1. [Assert](#): *parentPolicyContainer* is not null.
  2. Return a [clone](#)<sup>p917</sup> of *parentPolicyContainer*.
3. If *responseURL* [is local](#) and *initiatorPolicyContainer* is not null, then return a [clone](#)<sup>p917</sup> of *initiatorPolicyContainer*.
4. If *responsePolicyContainer* is not null, then return *responsePolicyContainer*.
5. Return a new [policy container](#)<sup>p917</sup>.

To **initialize a worker global scope's policy container** given a [WorkerGlobalScope](#)<sup>p1228</sup> *workerGlobalScope*, a [response](#) *response*, and an [environment](#)<sup>p1075</sup> *environment*:

1. If *workerGlobalScope*'s [url](#)<sup>p1229</sup> [is local](#) but its [scheme](#) is not "blob":
  1. [Assert](#): *workerGlobalScope*'s [owner set](#)<sup>p1228</sup>'s [size](#) is 1.
  2. Set *workerGlobalScope*'s [policy container](#)<sup>p1229</sup> to a [clone](#)<sup>p917</sup> of *workerGlobalScope*'s [owner set](#)<sup>p1228</sup>[0]'s [relevant settings object](#)<sup>p1083</sup>'s [policy container](#)<sup>p1076</sup>.
2. Otherwise, set *workerGlobalScope*'s [policy container](#)<sup>p1229</sup> to the result of [creating a policy container from a fetch response](#)<sup>p918</sup> given *response* and *environment*.

## 7.2 APIs related to navigation and session history §<sup>p91</sup><sub>9</sub>

### 7.2.1 Security infrastructure for [Window](#)<sup>p922</sup>, [WindowProxy](#)<sup>p934</sup>, and [Location](#)<sup>p937</sup> objects §<sup>p91</sup><sub>9</sub>

Although typically objects cannot be accessed across [origins](#)<sup>p898</sup>, the web platform would not be true to itself if it did not have some legacy exceptions to that rule that the web depends upon.

This section uses the terminology and typographic conventions from the JavaScript specification. [\[JAVASCRIPT\]](#)<sup>p1479</sup>

#### 7.2.1.1 Integration with IDL §<sup>p91</sup><sub>9</sub>

When [perform a security check](#) is invoked, with a *platformObject*, *identifier*, and *type*, run these steps:

1. If *platformObject* is not a [Window](#)<sup>p922</sup> or [Location](#)<sup>p937</sup> object, then return.
2. For each *e* of [CrossOriginProperties](#)<sup>p919</sup>(*platformObject*):
  1. If [SameValue](#)(*e*.[[Property]], *identifier*) is true, then:
    1. If *type* is "method" and *e* has neither [[NeedsGet]] nor [[NeedsSet]], then return.
    2. Otherwise, if *type* is "getter" and *e*.[[NeedsGet]] is true, then return.
    3. Otherwise, if *type* is "setter" and *e*.[[NeedsSet]] is true, then return.
3. If [IsPlatformObjectSameOrigin](#)<sup>p920</sup>(*platformObject*) is false, then throw a ["SecurityError" DOMException](#).

#### 7.2.1.2 Shared internal slot: [\[\[CrossOriginPropertyDescriptorMap\]\]](#) §<sup>p91</sup><sub>9</sub>

[Window](#)<sup>p922</sup> and [Location](#)<sup>p937</sup> objects both have a [\[\[CrossOriginPropertyDescriptorMap\]\]](#) internal slot, whose value is initially an empty map.

The [\[\[CrossOriginPropertyDescriptorMap\]\]](#)<sup>p919</sup> internal slot contains a map with entries whose keys are (*currentGlobal*, *objectGlobal*, *propertyKey*)-tuples and values are property descriptors, as a memoization of what is visible to scripts when *currentGlobal* inspects a [Window](#)<sup>p922</sup> or [Location](#)<sup>p937</sup> object from *objectGlobal*. It is filled lazily by [CrossOriginGetOwnPropertyHelper](#)<sup>p920</sup>, which consults it on future lookups.

User agents should allow a value held in the map to be garbage collected along with its corresponding key when nothing holds a reference to any part of the value. That is, as long as garbage collection is not observable.

#### Example

For example, with `const href = Object.getOwnPropertyDescriptor(crossOriginLocation, "href").set` the value and its corresponding key in the map cannot be garbage collected as that would be observable.

User agents may have an optimization whereby they remove key-value pairs from the map when [document.domain](#)<sup>p901</sup> is set. This is not observable as [document.domain](#)<sup>p901</sup> cannot revisit an earlier value.

#### Example

For example, setting [document.domain](#)<sup>p901</sup> to "example.com" on `www.example.com` means user agents can remove all key-value pairs from the map where part of the key is `www.example.com`, as that can never be part of the [origin](#)<sup>p898</sup> again and therefore the corresponding value could never be retrieved from the map.

#### 7.2.1.3 Shared abstract operations §<sup>p91</sup><sub>9</sub>

##### 7.2.1.3.1 [CrossOriginProperties](#) ( *O* ) §<sup>p91</sup><sub>9</sub>

1. [Assert](#): *O* is a [Location](#)<sup>p937</sup> or [Window](#)<sup>p922</sup> object.
2. If *O* is a [Location](#)<sup>p937</sup> object, then return « { [[Property]]: "href", [[NeedsGet]]: false, [[NeedsSet]]: true }, { [[Property]]:

"replace" } ».

3. Return « { [[Property]]: "window", [[NeedsGet]]: true, [[NeedsSet]]: false }, { [[Property]]: "self", [[NeedsGet]]: true, [[NeedsSet]]: false }, { [[Property]]: "location", [[NeedsGet]]: true, [[NeedsSet]]: true }, { [[Property]]: "close" }, { [[Property]]: "closed", [[NeedsGet]]: true, [[NeedsSet]]: false }, { [[Property]]: "focus" }, { [[Property]]: "blur" }, { [[Property]]: "frames", [[NeedsGet]]: true, [[NeedsSet]]: false }, { [[Property]]: "length", [[NeedsGet]]: true, [[NeedsSet]]: false }, { [[Property]]: "top", [[NeedsGet]]: true, [[NeedsSet]]: false }, { [[Property]]: "opener", [[NeedsGet]]: true, [[NeedsSet]]: false }, { [[Property]]: "parent", [[NeedsGet]]: true, [[NeedsSet]]: false }, { [[Property]]: "postMessage" } ».

#### Note

This abstract operation does not return a [Completion Record](#).

#### Note

Indexed properties do not need to be safelisted in this algorithm, as they are handled directly by the [WindowProxy](#)<sup>p934</sup> object.

A JavaScript property name *P* is a **cross-origin accessible window property name** if it is "window", "self", "location", "close", "closed", "focus", "blur", "frames", "length", "top", "opener", "parent", "postMessage", or an [array index property name](#).

#### 7.2.1.3.2 CrossOriginPropertyFallback ( *P* ) <sup>§ p92</sup><sub>0</sub>

1. If *P* is "then", [%Symbol.toStringTag%](#)<sup>p57</sup>, [%Symbol.hasInstance%](#)<sup>p57</sup>, or [%Symbol.isConcatSpreadable%](#)<sup>p57</sup>, then return [PropertyDescriptor](#){ [[Value]]: undefined, [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.
2. Throw a ["SecurityError" DOMException](#).

#### 7.2.1.3.3 IsPlatformObjectSameOrigin ( *O* ) <sup>§ p92</sup><sub>0</sub>

1. Return true if the [current settings object](#)<sup>p1083</sup>'s [origin](#)<sup>p1076</sup> is [same-origin-domain](#)<sup>p899</sup> with *O*'s [relevant settings object](#)<sup>p1083</sup>'s [origin](#)<sup>p1076</sup>, and false otherwise.

#### Note

This abstract operation does not return a [Completion Record](#).

#### Note

Here the [current settings object](#)<sup>p1083</sup> roughly corresponds to the "caller", because this check occurs before the [execution context](#) for the getter/setter/method in question makes its way onto the [JavaScript execution context stack](#). For example, in the code `w.document`, this step is invoked before the [document](#)<sup>p923</sup> getter is reached as part of the [\[\[Get\]\]](#)<sup>p935</sup> algorithm for the [WindowProxy](#)<sup>p934</sup> `w`.

#### 7.2.1.3.4 CrossOriginGetOwnPropertyHelper ( *O*, *P* ) <sup>§ p92</sup><sub>0</sub>

#### Note

If this abstract operation returns undefined and there is no custom behavior, the caller needs to throw a ["SecurityError" DOMException](#). In practice this is handled by the caller calling [CrossOriginPropertyFallback](#)<sup>p920</sup>.

1. Let *crossOriginKey* be a tuple consisting of the [current settings object](#)<sup>p1083</sup>, *O*'s [relevant settings object](#)<sup>p1083</sup>, and *P*.
2. For each *e* of [CrossOriginProperties](#)<sup>p919</sup>(*O*):
  1. If [SameValue](#)(*e*.[[Property]], *P*) is true, then:
    1. If the value of the [\[\[CrossOriginPropertyDescriptorMap\]\]](#)<sup>p919</sup> internal slot of *O* contains an entry whose key is *crossOriginKey*, then return that entry's value.
    2. Let *originalDesc* be [OrdinaryGetOwnProperty](#)(*O*, *P*).

3. Let *crossOriginDesc* be undefined.
  4. If *e*.[[NeedsGet]] and *e*.[[NeedsSet]] are absent, then:
    1. Let *value* be *originalDesc*.[[Value]].
    2. If *IsCallable*(*value*) is true, then set *value* to an anonymous built-in function, created in the [current realm](#), that performs the same steps as the IDL operation *P* on object *O*.
    3. Set *crossOriginDesc* to [PropertyDescriptor](#){ [[Value]]: *value*, [[Enumerable]]: false, [[Writable]]: false, [[Configurable]]: true }.
  5. Otherwise:
    1. Let *crossOriginGet* be undefined.
    2. If *e*.[[NeedsGet]] is true, then set *crossOriginGet* to an anonymous built-in function, created in the [current realm](#), that performs the same steps as the getter of the IDL attribute *P* on object *O*.
    3. Let *crossOriginSet* be undefined.
    4. If *e*.[[NeedsSet]] is true, then set *crossOriginSet* to an anonymous built-in function, created in the [current realm](#), that performs the same steps as the setter of the IDL attribute *P* on object *O*.
    5. Set *crossOriginDesc* to [PropertyDescriptor](#){ [[Get]]: *crossOriginGet*, [[Set]]: *crossOriginSet*, [[Enumerable]]: false, [[Configurable]]: true }.
  6. Create an entry in the value of the [\[\[CrossOriginPropertyDescriptorMap\]\]](#)<sup>p919</sup> internal slot of *O* with key *crossOriginKey* and value *crossOriginDesc*.
  7. Return *crossOriginDesc*.
3. Return undefined.

#### Note

*This abstract operation does not return a [Completion Record](#).*

#### Note

*The reason that the property descriptors produced here are configurable is to preserve the [invariants of the essential internal methods](#) required by the JavaScript specification. In particular, since the value of the property can change as a consequence of navigation, it is required that the property be configurable. (However, see [tc39/ecma262 issue #672](#) and references to it elsewhere in this specification for cases where we are not able to preserve these invariants, for compatibility with existing web content.)*  
[\[JAVASCRIPT\]](#)<sup>p1479</sup>

#### Note

*The reason the property descriptors are non-enumerable, despite this mismatching the same-origin behavior, is for compatibility with existing web content. See [issue #3183](#) for details.*

### 7.2.1.3.5 *CrossOriginGet* ( *O*, *P*, *Receiver* ) <sup>p92</sup><sub>1</sub>

1. Let *desc* be ? *O*.[[GetOwnProperty]](*P*).
2. [Assert](#): *desc* is not undefined.
3. If *IsDataDescriptor*(*desc*) is true, then return *desc*.[[Value]].
4. [Assert](#): *IsAccessorDescriptor*(*desc*) is true.
5. Let *getter* be *desc*.[[Get]].
6. If *getter* is undefined, then throw a "[SecurityError](#)" [DOMException](#).
7. Return ? [Call](#)(*getter*, *Receiver*).

### 7.2.1.3.6 *CrossOriginSet* ( *O*, *P*, *V*, *Receiver* ) §<sup>p92</sup><sub>2</sub>

1. Let *desc* be ? *O*.[[GetOwnProperty]](*P*).
2. [Assert](#): *desc* is not undefined.
3. If *desc*.[[Set]] is present and its value is not undefined, then:
  1. Perform ? [Call](#)(*setter*, *Receiver*, « *V* »).
  2. Return true.
4. Throw a ["SecurityError" DOMException](#).

### 7.2.1.3.7 *CrossOriginOwnPropertyKeys* ( *O* ) §<sup>p92</sup><sub>2</sub>

1. Let *keys* be a new empty [List](#).
2. For each *e* of [CrossOriginProperties](#)<sup>p919</sup>(*O*), [append](#) *e*.[[Property]] to *keys*.
3. Return the concatenation of *keys* and « "then", [%Symbol.toStringTag%](#)<sup>p57</sup>, [%Symbol.hasInstance%](#)<sup>p57</sup>, [%Symbol.isConcatSpreadable%](#)<sup>p57</sup> ».

#### Note

This abstract operation does not return a [Completion Record](#).

## 7.2.2 The [Window](#)<sup>p922</sup> object §<sup>p92</sup><sub>2</sub>

IDL

```
[Global=Window,
Exposed=Window,
LegacyUnenumerableNamedProperties]
interface Window : EventTarget {
  // the current browsing context
  [LegacyUnforgeable] readonly attribute WindowProxy window;
  [Replaceable] readonly attribute WindowProxy self;
  [LegacyUnforgeable] readonly attribute Document document;
  attribute DOMString name;
  [PutForwards=href, LegacyUnforgeable] readonly attribute Location location;
  readonly attribute History history;
  readonly attribute Navigation navigation;
  readonly attribute CustomElementRegistry customElements;
  [Replaceable] readonly attribute BarProp locationbar;
  [Replaceable] readonly attribute BarProp menubar;
  [Replaceable] readonly attribute BarProp personalbar;
  [Replaceable] readonly attribute BarProp scrollbar;
  [Replaceable] readonly attribute BarProp statusbar;
  [Replaceable] readonly attribute BarProp toolbar;
  attribute DOMString status;
  undefined close();
  readonly attribute boolean closed;
  undefined stop();
  undefined focus();
  undefined blur();

  // other browsing contexts
  [Replaceable] readonly attribute WindowProxy frames;
  [Replaceable] readonly attribute unsigned long length;
  [LegacyUnforgeable] readonly attribute WindowProxy? top;
```

```

attribute any opener;
[Replaceable] readonly attribute WindowProxy? parent;
readonly attribute Element? frameElement;
WindowProxy? open(optional USVString url = "", optional DOMString target = "_blank", optional
[LegacyNullToEmptyString] DOMString features = "");

// Since this is the global object, the IDL named getter adds a NamedPropertiesObject exotic
// object on the prototype chain. Indeed, this does not make the global object an exotic object.
// Indexed access is taken care of by the WindowProxy exotic object.
getter object (DOMString name);

// the user agent
readonly attribute Navigator navigator;
[Replaceable] readonly attribute Navigator clientInformation; // legacy alias of .navigator
readonly attribute boolean originAgentCluster;

// user prompts
undefined alert();
undefined alert(DOMString message);
boolean confirm(optional DOMString message = "");
DOMString? prompt(optional DOMString message = "", optional DOMString default = "");
undefined print();

undefined postMessage(any message, USVString targetOrigin, optional sequence<object> transfer = []);
undefined postMessage(any message, optional WindowPostMessageOptions options = {});

// also has obsolete members
};
Window includes GlobalEventHandlers;
Window includes WindowEventHandlers;

dictionary WindowPostMessageOptions : StructuredSerializeOptions {
  USVString targetOrigin = "/";
};

```

#### For web developers (non-normative)

`window.window`<sup>p923</sup>

`window.frames`<sup>p923</sup>

`window.self`<sup>p923</sup>

These attributes all return *window*.

`window.document`<sup>p923</sup>

Returns the *Document*<sup>p130</sup> associated with *window*.

`document.defaultView`<sup>p924</sup>

Returns the *Window*<sup>p922</sup> associated with *document*, if there is one, or null otherwise.

The *Window*<sup>p922</sup> object has an **associated Document**, which is a *Document*<sup>p130</sup> object. It is set when the *Window*<sup>p922</sup> object is created, and only ever changed during *navigation*<sup>p1014</sup> from the *initial about:blank*<sup>p131</sup> *Document*<sup>p130</sup>.

A *Window*<sup>p922</sup>'s **browsing context** is its *associated Document*<sup>p923</sup>'s *browsing context*<sup>p999</sup>. **Note** *It is either null or a browsing context*<sup>p998</sup>.

A *Window*<sup>p922</sup>'s **navigable** is the *navigable*<sup>p989</sup> whose *active document*<sup>p989</sup> is the *Window*<sup>p922</sup>'s *associated Document*<sup>p923</sup>'s, or null if there is no such *navigable*<sup>p989</sup>.

The **window**, **frames**, and **self** getter steps are to return *this*'s *relevant realm*<sup>p1083</sup>.*[[GlobalEnv]].[[GlobalThisValue]]*.

The **document** getter steps are to return *this*'s *associated Document*<sup>p923</sup>.

## Note

The [Document](#)<sup>p130</sup> object associated with a [Window](#)<sup>p922</sup> object can change in exactly one case: when the [navigate](#)<sup>p1014</sup> algorithm creates a new [Document object](#)<sup>p1056</sup> for the first page loaded in a [browsing context](#)<sup>p998</sup>. In that specific case, the [Window](#)<sup>p922</sup> object of the [initial about:blank](#)<sup>p131</sup> page is reused and gets a new [Document](#)<sup>p130</sup> object.

The [defaultView](#) getter steps are:

1. If [this's browsing context](#)<sup>p999</sup> is null, then return null.
2. Return [this's browsing context](#)<sup>p999</sup>'s [WindowProxy](#)<sup>p934</sup> object.

For historical reasons, [Window](#)<sup>p922</sup> objects must also have a writable, configurable, non-enumerable property named [HTMLDocument](#)<sup>MDN</sup> whose value is the [Document](#)<sup>p130</sup> interface object.

### 7.2.2.1 Opening and closing windows § p924

For web developers (non-normative)

**`window = window.open`**<sup>p926</sup>( [ *url* [ , *target* [ , *features* ] ] ] )

Opens a window to show *url* (defaults to "[about:blank](#)<sup>p53</sup>"), and returns it. *target* (defaults to "[\\_blank](#)") gives the name of the new window. If a window already exists with that name, it is reused. The *features* argument can contain a [set of comma-separated tokens](#)<sup>p95</sup>:

"noopener"

"noreferrer"

These behave equivalently to the [noopener](#)<sup>p325</sup> and [noreferrer](#)<sup>p325</sup> link types on [hyperlinks](#)<sup>p302</sup>.

"popup"

Encourages user agents to provide a minimal web browser user interface for the new window. (Impacts the [visible](#)<sup>p932</sup> getter on all [BarProp](#)<sup>p932</sup> objects as well.)

#### Example

```
globalThis.open("https://email.example/message/CA000kFcWW97r8yg=SsWg7GgCmp4suVX9o85y8BvNRqMjuc5PXg", undefined, "noopener,popup");
```

**`window.name`**<sup>p927</sup> [ = *value* ]

Returns the name of the window.

Can be set, to change the name.

**`window.close`**<sup>p928</sup> ()

Closes the window.

**`window.closed`**<sup>p928</sup>

Returns true if the window has been closed, false otherwise.

**`window.stop`**<sup>p928</sup> ()

Cancels the document load.

To **get opener for window open**, given a [Document](#)<sup>p130</sup> *sourceDocument*, an [ordered map](#) *tokenizedFeatures*, and a [URL record](#) *url*, perform the following steps. They return a boolean.

1. If *url's* [scheme](#) is "blob":
  1. Let *blobOrigin* be *url's* [blob URL entry's environment's origin](#)<sup>p1076</sup>.
  2. Let *topLevelOrigin* be *sourceDocument's* [relevant settings object](#)<sup>p1083</sup>'s [top-level origin](#)<sup>p1076</sup>.
  3. If *blobOrigin* is not [same site](#)<sup>p900</sup> with *topLevelOrigin*, then return true.
2. Let *noopener* be false.

3. If `tokenizedFeatures["noopener"]` [exists](#), then set `noopener` to the result of [parsing tokenizedFeatures\["noopener"\] as a boolean feature](#)<sup>p927</sup>.
4. Return `noopener`.

The **window open steps**, given a string `url`, a string `target`, and a string `features`, are as follows:

1. If the [event loop](#)<sup>p1123</sup>'s [termination nesting level](#)<sup>p1064</sup> is nonzero, then return null.
2. Let `sourceDocument` be the [entry global object](#)<sup>p1080</sup>'s [associated Document](#)<sup>p923</sup>.
3. Let `urlRecord` be null.
4. If `url` is not the empty string, then:
  1. Set `urlRecord` to the result of [encoding-parsing a URL](#)<sup>p97</sup> given `url`, relative to `sourceDocument`.
  2. If `urlRecord` is failure, then throw a ["SyntaxError" DOMException](#).
5. If `target` is the empty string, then set `target` to `"_blank"`.
6. Let `tokenizedFeatures` be the result of [tokenizing](#)<sup>p926</sup> `features`.
7. Let `noreferrer` be false.
8. If `tokenizedFeatures["noreferrer"]` [exists](#), then set `noreferrer` to the result of [parsing tokenizedFeatures\["noreferrer"\] as a boolean feature](#)<sup>p927</sup>.
9. Let `noopener` be the result of [getting noopener for window open](#)<sup>p924</sup> with `sourceDocument`, `tokenizedFeatures`, and `urlRecord`.
10. [Remove](#) `tokenizedFeatures["noopener"]` and `tokenizedFeatures["noreferrer"]`.
11. Let `referrerPolicy` be the empty string.
12. If `noreferrer` is true, then set `noopener` to true and set `referrerPolicy` to `"no-referrer"`.
13. Let `targetNavigable` and `windowType` be the result of applying [the rules for choosing a navigable](#)<sup>p997</sup> given `target`, `sourceDocument`'s [node navigable](#)<sup>p989</sup>, and `noopener`.

#### Example

If there is a user agent that supports control-clicking a link to open it in a new tab, and the user control-clicks on an element whose [onclick](#)<sup>p1144</sup> handler uses the [window.open\(\)](#)<sup>p926</sup> API to open a page in an [iframe](#)<sup>p399</sup> element, the user agent could override the selection of the target browsing context to instead target a new tab.

14. If `targetNavigable` is null, then return null.
15. If `windowType` is either `"new and unrestricted"` or `"new with no opener"`, then:
  1. Set `targetNavigable`'s [active browsing context](#)<sup>p989</sup>'s [is popup](#)<sup>p998</sup> to the result of [checking if a popup window is requested](#)<sup>p927</sup>, given `tokenizedFeatures`.
  2. [Set up browsing context features](#) for `targetNavigable`'s [active browsing context](#)<sup>p989</sup> given `tokenizedFeatures`. [\[CSSOMVIEW\]](#)<sup>p1477</sup>
  3. If `urlRecord` is null, then set `urlRecord` to a [URL record](#) representing [about:blank](#)<sup>p53</sup>.
  4. If `urlRecord` [matches about:blank](#)<sup>p96</sup>, then perform the [URL and history update steps](#)<sup>p1028</sup> given `targetNavigable`'s [active document](#)<sup>p989</sup> and `urlRecord`.

#### Note

*This is necessary in case url is something like `about:blank?foo`. If url is just plain `about:blank`, this will do nothing.*

5. Otherwise, [navigate](#)<sup>p1014</sup> `targetNavigable` to `urlRecord` using `sourceDocument`, with [referrerPolicy](#)<sup>p1014</sup> set to `referrerPolicy` and [exceptionsEnabled](#)<sup>p1014</sup> set to true.
16. Otherwise:
  1. If `urlRecord` is not null, then [navigate](#)<sup>p1014</sup> `targetNavigable` to `urlRecord` using `sourceDocument`, with

[referrerPolicy](#)<sup>p1014</sup> set to `referrerPolicy` and [exceptionsEnabled](#)<sup>p1014</sup> set to `true`.

2. If `noopener` is `false`, then set `targetNavigable`'s [active browsing context](#)<sup>p989</sup>'s [opener browsing context](#)<sup>p998</sup> to `sourceDocument`'s [browsing context](#)<sup>p999</sup>.
17. If `noopener` is `true` or `windowType` is `"new with no opener"`, then return `null`.
18. Return `targetNavigable`'s [active WindowProxy](#)<sup>p989</sup>.

The `open(url, target, features)` method steps are to run the [window open steps](#)<sup>p925</sup> with `url`, `target`, and `features`.

#### Note

The method provides a mechanism for [navigating](#)<sup>p1014</sup> an existing [browsing context](#)<sup>p998</sup> or opening and navigating an [auxiliary browsing context](#)<sup>p999</sup>.

To **tokenize the features argument**:

1. Let `tokenizedFeatures` be a new [ordered map](#).
2. Let `position` point at the first code point of `features`.
3. [While](#) `position` is not past the end of `features`:
  1. Let `name` be the empty string.
  2. Let `value` be the empty string.
  3. [Collect a sequence of code points](#) that are [feature separators](#)<sup>p927</sup> from `features` given `position`. This skips past leading separators before the name.
  4. [Collect a sequence of code points](#) that are not [feature separators](#)<sup>p927</sup> from `features` given `position`. Set `name` to the collected characters, [converted to ASCII lowercase](#).
  5. Set `name` to the result of [normalizing the feature name](#)<sup>p927</sup> `name`.
  6. [While](#) `position` is not past the end of `features` and the code point at `position` in `features` is not U+003D (=):
    1. If the code point at `position` in `features` is U+002C (,), or if it is not a [feature separator](#)<sup>p927</sup>, then [break](#).
    2. Advance `position` by 1.

#### Note

This skips to the first U+003D (=) but does not skip past a U+002C (,) or a non-separator.

7. If the code point at `position` in `features` is a [feature separator](#)<sup>p927</sup>:
  1. [While](#) `position` is not past the end of `features` and the code point at `position` in `features` is a [feature separator](#)<sup>p927</sup>:
    1. If the code point at `position` in `features` is U+002C (,), then [break](#).
    2. Advance `position` by 1.

#### Note

This skips to the first non-separator but does not skip past a U+002C (,).

2. [Collect a sequence of code points](#) that are not [feature separators](#)<sup>p927</sup> code points from `features` given `position`. Set `value` to the collected code points, [converted to ASCII lowercase](#).
8. If `name` is not the empty string, then set `tokenizedFeatures[name]` to `value`.
4. Return `tokenizedFeatures`.

To **check if a window feature is set**, given `tokenizedFeatures`, `featureName`, and `defaultValue`:

1. If `tokenizedFeatures[featureName]` [exists](#), then return the result of [parsing tokenizedFeatures\[featureName\] as a boolean feature](#)<sup>p927</sup>.

2. Return *defaultValue*.

To **check if a popup window is requested**, given *tokenizedFeatures*:

1. If *tokenizedFeatures* is [empty](#), then return false.
2. If *tokenizedFeatures*["popup"] [exists](#), then return the result of [parsing tokenizedFeatures\["popup"\] as a boolean feature](#)<sup>p927</sup>.
3. Let *location* be the result of [checking if a window feature is set](#)<sup>p926</sup>, given *tokenizedFeatures*, "location", and false.
4. Let *toolbar* be the result of [checking if a window feature is set](#)<sup>p926</sup>, given *tokenizedFeatures*, "toolbar", and false.
5. If *location* and *toolbar* are both false, then return true.
6. Let *menubar* be the result of [checking if a window feature is set](#)<sup>p926</sup>, given *tokenizedFeatures*, "menubar", and false.
7. If *menubar* is false, then return true.
8. Let *resizable* be the result of [checking if a window feature is set](#)<sup>p926</sup>, given *tokenizedFeatures*, "resizable", and true.
9. If *resizable* is false, then return true.
10. Let *scrollbars* be the result of [checking if a window feature is set](#)<sup>p926</sup>, given *tokenizedFeatures*, "scrollbars", and false.
11. If *scrollbars* is false, then return true.
12. Let *status* be the result of [checking if a window feature is set](#)<sup>p926</sup>, given *tokenizedFeatures*, "status", and false.
13. If *status* is false, then return true.
14. Return false.

A code point is a **feature separator** if it is [ASCII whitespace](#), U+003D (=), or U+002C (,).

For legacy reasons, there are some aliases of some feature names. To **normalize a feature name** *name*, switch on *name*:

- ↪ "screenx"  
Return "left".
- ↪ "screeny"  
Return "top".
- ↪ "innerwidth"  
Return "width".
- ↪ "innerheight"  
Return "height".
- ↪ **Anything else**  
Return *name*.

To **parse a boolean feature** given a string *value*:

1. If *value* is the empty string, then return true.
2. If *value* is "yes", then return true.
3. If *value* is "true", then return true.
4. Let *parsed* be the result of [parsing value as an integer](#)<sup>p76</sup>.
5. If *parsed* is an error, then set it to 0.
6. Return false if *parsed* is 0, and true otherwise.

The **name** getter steps are:

1. If [this's navigable](#)<sup>p923</sup> is null, then return the empty string.
2. Return [this's navigable](#)<sup>p923</sup>'s [target name](#)<sup>p989</sup>.

The **name**<sup>p927</sup> setter steps are:

1. If **this**'s **navigable**<sup>p923</sup> is null, then return.
2. Set **this**'s **navigable**<sup>p923</sup>'s **active session history entry**<sup>p989</sup>'s **document state**<sup>p1005</sup>'s **navigable target name**<sup>p1007</sup> to the given value.

#### Note

The name **gets reset**<sup>p1018</sup> when the navigable is **navigated**<sup>p1014</sup> to another **origin**<sup>p898</sup>.

The **close()** method steps are:

1. Let *thisTraversable* be **this**'s **navigable**<sup>p923</sup>.
2. If *thisTraversable* is not a **top-level traversable**<sup>p990</sup>, then return.
3. If *thisTraversable*'s **is closing**<sup>p989</sup> is true, then return.
4. Let *browsingContext* be *thisTraversable*'s **active browsing context**<sup>p989</sup>.
5. Let *sourceSnapshotParams* be the result of **snapshotting source snapshot params**<sup>p1012</sup> given *thisTraversable*'s **active document**<sup>p989</sup>.
6. If all the following are true:
  - *thisTraversable* is **script-closable**<sup>p928</sup>;
  - the **incumbent global object**<sup>p1081</sup>'s **browsing context**<sup>p923</sup> is **familiar with**<sup>p1002</sup> *browsingContext*; and
  - the **incumbent global object**<sup>p1081</sup>'s **navigable**<sup>p923</sup> is **allowed by sandboxing to navigate**<sup>p1025</sup> *thisTraversable*, given *sourceSnapshotParams*,

then:

1. Set *thisTraversable*'s **is closing**<sup>p989</sup> to true.
2. **Queue a task**<sup>p1125</sup> on the **DOM manipulation task source**<sup>p1134</sup> to **definitely close**<sup>p996</sup> *thisTraversable*.

A **navigable**<sup>p989</sup> is **script-closable** if its **active browsing context**<sup>p989</sup> is an **auxiliary browsing context**<sup>p999</sup> that was created by a script (as opposed to by an action of the user), or if it is a **top-level traversable**<sup>p990</sup> whose **session history entries**<sup>p990</sup>'s **size** is 1.

The **closed** getter steps are to return true if **this**'s **browsing context**<sup>p923</sup> is null or its **is closing**<sup>p989</sup> is true; otherwise false.

The **stop()** method steps are:

1. If **this**'s **navigable**<sup>p923</sup> is null, then return.
2. **Stop loading**<sup>p1067</sup> **this**'s **navigable**<sup>p923</sup>.

### 7.2.2.2 Indexed access on the **Window**<sup>p922</sup> object §<sup>p92</sup><sub>8</sub>

For web developers (non-normative)

**window.length**<sup>p928</sup>

Returns the number of **document-tree child navigables**<sup>p995</sup>.

**window[index]**

Returns the **WindowProxy**<sup>p934</sup> corresponding to the indicated **document-tree child navigables**<sup>p995</sup>.

The **length** getter steps are to return **this**'s **associated Document**<sup>p923</sup>'s **document-tree child navigables**<sup>p995</sup>'s **size**.

#### Note

Indexed access to **document-tree child navigables**<sup>p995</sup> is defined through the **[[GetOwnProperty]]**<sup>p934</sup> internal method of the

[WindowProxy<sup>p934</sup>](#) object.

### 7.2.2.3 Named access on the [Window<sup>p922</sup>](#) object <sup>§<sup>p92</sup><sub>9</sub></sup>

For web developers (non-normative)

**`window[name]`**

Returns the indicated element or collection of elements.

As a general rule, relying on this will lead to brittle code. Which IDs end up mapping to this API can vary over time, as new features are added to the web platform, for example. Instead of this, use `document.getElementById()` or `document.querySelector()`.

The **document-tree child navigable target name property set** of a [Window<sup>p922</sup>](#) object *window* is the return value of running these steps:

1. Let *children* be the [document-tree child navigables<sup>p995</sup>](#) of *window*'s [associated Document<sup>p923</sup>](#).
2. Let *firstNamedChildren* be an empty [ordered set](#).
3. **For each** *navigable* of *children*:
  1. Let *name* be *navigable*'s [target name<sup>p989</sup>](#).
  2. If *name* is the empty string, then **continue**.
  3. If *firstNamedChildren* **contains** a [navigable<sup>p989</sup>](#) whose [target name<sup>p989</sup>](#) is *name*, then **continue**.
  4. **Append** *navigable* to *firstNamedChildren*.
4. Let *names* be an empty [ordered set](#).
5. **For each** *navigable* of *firstNamedChildren*:
  1. Let *name* be *navigable*'s [target name<sup>p989</sup>](#).
  2. If *navigable*'s [active document<sup>p989</sup>](#)'s [origin](#) is [same origin<sup>p899</sup>](#) with *window*'s [relevant settings object<sup>p1083</sup>](#)'s [origin<sup>p1076</sup>](#), then **append** *name* to *names*.
6. Return *names*.

#### Example

The two separate iterations mean that in the following example, hosted on `https://example.org/`, assuming `https://elsewhere.example/` sets [window.name<sup>p927</sup>](#) to "spices", evaluating `window.spices` after everything has loaded will yield undefined:

```
<iframe src=https://elsewhere.example.com/></iframe>
<iframe name=spices></iframe>
```

The [Window<sup>p922</sup>](#) object **supports named properties**. The [supported property names](#) of a [Window<sup>p922</sup>](#) object *window* at any moment consist of the following, in [tree order](#) according to the element that contributed them, ignoring later duplicates:

- *window*'s [document-tree child navigable target name property set<sup>p929</sup>](#);
- the value of the `name` content attribute for all [embed<sup>p399</sup>](#), [form<sup>p514</sup>](#), [img<sup>p346</sup>](#), and [object<sup>p482</sup>](#) elements that have a non-empty `name` content attribute and are [in a document tree](#) with *window*'s [associated Document<sup>p923</sup>](#) as their [root](#); and
- the value of the [id<sup>p154</sup>](#) content attribute for all [HTML elements<sup>p45</sup>](#) that have a non-empty [id<sup>p154</sup>](#) content attribute and are [in a document tree](#) with *window*'s [associated Document<sup>p923</sup>](#) as their [root](#).

To [determine the value of a named property](#) *name* in a [Window<sup>p922</sup>](#) object *window*, the user agent must return the value obtained using the following steps:

1. Let *objects* be the list of [named objects](#)<sup>p930</sup> of *window* with the name *name*.

#### Note

*There will be at least one such object, since the algorithm would otherwise not have been [invoked by Web IDL](#).*

2. If *objects* contains a [navigable](#)<sup>p989</sup>, then:
  1. Let *container* be the first [navigable container](#)<sup>p991</sup> in *window*'s [associated Document](#)<sup>p923</sup>'s [descendants](#) whose [content navigable](#)<sup>p991</sup> is in *objects*.
  2. Return *container*'s [content navigable](#)<sup>p991</sup>'s [active WindowProxy](#)<sup>p989</sup>.
3. Otherwise, if *objects* has only one element, return that element.
4. Otherwise, return an [HTMLCollection](#) rooted at *window*'s [associated Document](#)<sup>p923</sup>, whose filter matches only [named objects](#)<sup>p930</sup> of *window* with the name *name*. (By definition, these will all be elements.)

**Named objects** of [Window](#)<sup>p922</sup> object *window* with the name *name*, for the purposes of the above algorithm, consist of the following:

- [document-tree child navigables](#)<sup>p995</sup> of *window*'s [associated Document](#)<sup>p923</sup> whose [target name](#)<sup>p989</sup> is *name*;
- [embed](#)<sup>p399</sup>, [form](#)<sup>p514</sup>, [img](#)<sup>p346</sup>, or [object](#)<sup>p402</sup> elements that have a [name](#) content attribute whose value is *name* and are [in a document tree](#) with *window*'s [associated Document](#)<sup>p923</sup> as their [root](#); and
- [HTML elements](#)<sup>p45</sup> that have an [id](#)<sup>p154</sup> content attribute whose value is *name* and are [in a document tree](#) with *window*'s [associated Document](#)<sup>p923</sup> as their [root](#).

#### Note

*Since the [Window](#)<sup>p922</sup> interface has the [\[Global\]](#) extended attribute, its named properties follow the rules for [named properties objects](#) rather than [legacy platform objects](#).*

### 7.2.2.4 Accessing related windows §<sup>p93</sup><sub>0</sub>

For web developers (non-normative)

**[window.top](#)**<sup>p930</sup>

Returns the [WindowProxy](#)<sup>p934</sup> for the [top-level traversable](#)<sup>p990</sup>.

**[window.opener](#)**<sup>p930</sup> [ = *value* ]

Returns the [WindowProxy](#)<sup>p934</sup> for the [opener browsing context](#)<sup>p998</sup>.

Returns null if there isn't one or if it has been set to null.

Can be set to null.

**[window.parent](#)**<sup>p931</sup>

Returns the [WindowProxy](#)<sup>p934</sup> for the [parent navigable](#)<sup>p989</sup>.

**[window.frameElement](#)**<sup>p931</sup>

Returns the [navigable container](#)<sup>p991</sup> element.

Returns null if there isn't one, and in cross-origin situations.

The **top** getter steps are:

1. If *this*'s [navigable](#)<sup>p923</sup> is null, then return null.
2. Return *this*'s [navigable](#)<sup>p923</sup>'s [top-level traversable](#)<sup>p990</sup>'s [active WindowProxy](#)<sup>p989</sup>.

The **opener** getter steps are:

1. Let *current* be *this*'s [browsing context](#)<sup>p923</sup>.
2. If *current* is null, then return null.
3. If *current*'s [opener browsing context](#)<sup>p998</sup> is null, then return null.

4. Return *current*'s [opener browsing context](#)<sup>p998</sup>'s [WindowProxy](#)<sup>p934</sup> object.

The [opener](#)<sup>p930</sup> setter steps are:

1. If the given value is null and *this*'s [browsing context](#)<sup>p923</sup> is non-null, then set *this*'s [browsing context](#)<sup>p923</sup>'s [opener browsing context](#)<sup>p998</sup> to null.
2. If the given value is non-null, then perform ? [DefinePropertyOrThrow](#)(*this*, "opener", { [[Value]]: the given value, [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true }).

#### Note

Setting [window.opener](#)<sup>p930</sup> to null clears the [opener browsing context](#)<sup>p998</sup> reference. In practice, this prevents future scripts from accessing their [opener browsing context](#)<sup>p998</sup>'s [Window](#)<sup>p922</sup> object.

By default, scripts can access their [opener browsing context](#)<sup>p998</sup>'s [Window](#)<sup>p922</sup> object through the [window.opener](#)<sup>p930</sup> getter. E.g., a script can set `window.opener.location`, causing the [opener browsing context](#)<sup>p998</sup> to navigate.

The [parent](#) getter steps are:

1. Let *navigable* be *this*'s [navigable](#)<sup>p923</sup>.
2. If *navigable* is null, then return null.
3. If *navigable*'s [parent](#)<sup>p989</sup> is not null, then set *navigable* to *navigable*'s [parent](#)<sup>p989</sup>.
4. Return *navigable*'s [active WindowProxy](#)<sup>p989</sup>.

The [frameElement](#) getter steps are:

1. Let *current* be *this*'s [node navigable](#)<sup>p989</sup>.
2. If *current* is null, then return null.
3. Let *container* be *current*'s [container](#)<sup>p991</sup>.
4. If *container* is null, then return null.
5. If *container*'s [node document](#)'s [origin](#) is not [same origin-domain](#)<sup>p899</sup> with the [current settings object](#)<sup>p1083</sup>'s [origin](#)<sup>p1076</sup>, then return null.
6. Return *container*.

#### Example

An example of when these properties can return null is as follows:

```
<!DOCTYPE html>
<iframe></iframe>

<script>
  "use strict";
  const element = document.querySelector("iframe");
  const iframeWindow = element.contentWindow;
  element.remove();

  console.assert(iframeWindow.top === null);
  console.assert(iframeWindow.parent === null);
  console.assert(iframeWindow.frameElement === null);
</script>
```

Here the [browsing context](#)<sup>p998</sup> corresponding to `iframeWindow` was [nulled out](#)<sup>p1066</sup> when `element` was removed from the document.

### 7.2.2.5 Historical browser interface element APIs <sup>p93</sup><sub>2</sub>

For historical reasons, the [Window](#)<sup>p922</sup> interface had some properties that represented the visibility of certain web browser interface elements.

For privacy and interoperability reasons, those properties now return values that represent whether the [Window](#)<sup>p922</sup>'s [browsing context](#)<sup>p923</sup>'s [is.popup](#)<sup>p998</sup> property is true or false.

Each interface element is represented by a [BarProp](#)<sup>p932</sup> object:

```
IDL [Exposed=Window]
interface BarProp {
  readonly attribute boolean visible;
};
```

For web developers (non-normative)

```
window.locationbarp932.visiblep932
window.menubarp932.visiblep932
window.personalbarp932.visiblep932
window.scrollbarsp932.visiblep932
window.statusbarp933.visiblep932
window.toolbarp933.visiblep932
```

Returns true if the [Window](#)<sup>p922</sup> is not a popup; otherwise, returns false.

The **visible** getter steps are:

1. Let *browsingContext* be [this](#)'s [relevant global object](#)<sup>p1083</sup>'s [browsing context](#)<sup>p923</sup>.
2. If *browsingContext* is null, then return true.
3. Return the negation of *browsingContext*'s [top-level browsing context](#)<sup>p1001</sup>'s [is.popup](#)<sup>p998</sup>.

The following [BarProp](#)<sup>p932</sup> objects must exist for each [Window](#)<sup>p922</sup> object:

#### The location bar [BarProp](#) object

Historically represented the user interface element that contains a control that displays the browser's location bar.

#### The menu bar [BarProp](#) object

Historically represented the user interface element that contains a list of commands in menu form, or some similar interface concept.

#### The personal bar [BarProp](#) object

Historically represented the user interface element that contains links to the user's favorite pages, or some similar interface concept.

#### The scrollbar [BarProp](#) object

Historically represented the user interface element that contains a scrolling mechanism, or some similar interface concept.

#### The status bar [BarProp](#) object

Historically represented a user interface element found immediately below or after the document, as appropriate for the user's media, which typically provides information about ongoing network activity or information about elements that the user's pointing device is currently indicating.

#### The toolbar [BarProp](#) object

Historically represented the user interface element found immediately above or before the document, as appropriate for the user's media, which typically provides [session history traversal](#)<sup>p1040</sup> controls (back and forward buttons, reload buttons, etc.).

The **locationbar** attribute must return [the location bar \[BarProp\]\(#\) object](#)<sup>p932</sup>.

The **menubar** attribute must return [the menu bar \[BarProp\]\(#\) object](#)<sup>p932</sup>.

The **personalbar** attribute must return [the personal bar \[BarProp\]\(#\) object](#)<sup>p932</sup>.

The **scrollbars** attribute must return [the scrollbar \[BarProp\]\(#\) object](#)<sup>p932</sup>.

The **statusbar** attribute must return [the status bar BarProp object](#)<sup>p932</sup>.

The **toolbar** attribute must return [the toolbar BarProp object](#)<sup>p932</sup>.

For historical reasons, the **status** attribute on the [Window](#)<sup>p922</sup> object must, on getting, return the last string it was set to, and on setting, must set itself to the new value. When the [Window](#)<sup>p922</sup> object is created, the attribute must be set to the empty string. It does not do anything else.

#### 7.2.2.6 Script settings for [Window](#)<sup>p922</sup> objects § p933

To **set up a window environment settings object**, given a [URL](#) *creationURL*, a [JavaScript execution context](#) *execution context*, null or an [environment](#)<sup>p1075</sup> *reservedEnvironment*, a [URL](#) *topLevelCreationURL*, and an [origin](#)<sup>p898</sup> *topLevelOrigin*, run these steps:

1. Let *realm* be the value of *execution context*'s Realm component.
2. Let *window* be *realm*'s [global object](#)<sup>p1077</sup>.
3. Let *settings object* be a new [environment settings object](#)<sup>p1076</sup> whose algorithms are defined as follows:

**The [realm execution context](#)**<sup>p1076</sup>

Return *execution context*.

**The [module map](#)**<sup>p1076</sup>

Return the [module map](#)<sup>p131</sup> of *window*'s [associated Document](#)<sup>p923</sup>.

**The [API base URL](#)**<sup>p1076</sup>

Return the current [base URL](#)<sup>p96</sup> of *window*'s [associated Document](#)<sup>p923</sup>.

**The [origin](#)**<sup>p1076</sup>

Return the [origin](#) of *window*'s [associated Document](#)<sup>p923</sup>.

**The [policy container](#)**<sup>p1076</sup>

Return the [policy container](#)<sup>p131</sup> of *window*'s [associated Document](#)<sup>p923</sup>.

**The [cross-origin isolated capability](#)**<sup>p1076</sup>

Return true if both of the following hold, and false otherwise:

- *realm*'s [agent cluster](#)'s [cross-origin-isolation mode](#)<sup>p1073</sup> is "[concrete](#)<sup>p1002</sup>", and
- *window*'s [associated Document](#)<sup>p923</sup> is [allowed to use](#)<sup>p398</sup> the "[cross-origin-isolated](#)<sup>p75</sup>" feature.

**The [time origin](#)**<sup>p1076</sup>

Return *window*'s [associated Document](#)<sup>p923</sup>'s [load timing info](#)<sup>p134</sup>'s [navigation start time](#)<sup>p134</sup>.

4. If *reservedEnvironment* is non-null, then:
  1. Set *settings object*'s [id](#)<sup>p1075</sup> to *reservedEnvironment*'s [id](#)<sup>p1075</sup>, [target browsing context](#)<sup>p1076</sup> to *reservedEnvironment*'s [target browsing context](#)<sup>p1076</sup>, and [active service worker](#)<sup>p1076</sup> to *reservedEnvironment*'s [active service worker](#)<sup>p1076</sup>.
  2. Set *reservedEnvironment*'s [id](#)<sup>p1075</sup> to the empty string.

**Note**

*The identity of the reserved environment is considered to be fully transferred to the created [environment settings object](#)<sup>p1076</sup>. The reserved environment is not searchable by the [environment](#)<sup>p1075</sup>'s [id](#)<sup>p1075</sup> from this point on.*

5. Otherwise, set *settings object*'s [id](#)<sup>p1075</sup> to a new unique opaque string, *settings object*'s [target browsing context](#)<sup>p1076</sup> to null, and *settings object*'s [active service worker](#)<sup>p1076</sup> to null.
6. Set *settings object*'s [creation URL](#)<sup>p1075</sup> to *creationURL*, *settings object*'s [top-level creation URL](#)<sup>p1075</sup> to *topLevelCreationURL*, and *settings object*'s [top-level origin](#)<sup>p1076</sup> to *topLevelOrigin*.

7. Set *realm*'s `[[HostDefined]]` field to *settings object*.

### 7.2.3 The `WindowProxy`<sup>p934</sup> exotic object § p934

A `WindowProxy` is an exotic object that wraps a `Window`<sup>p922</sup> ordinary object, indirecting most operations through to the wrapped object. Each `browsing context`<sup>p998</sup> has an associated `WindowProxy`<sup>p934</sup> object. When the `browsing context`<sup>p998</sup> is `navigated`<sup>p1014</sup>, the `Window`<sup>p922</sup> object wrapped by the `browsing context`<sup>p998</sup>'s associated `WindowProxy`<sup>p934</sup> object is changed.

The `WindowProxy`<sup>p934</sup> exotic object must use the ordinary internal methods except where it is explicitly specified otherwise below.

There is no `WindowProxy`<sup>p934</sup> interface object.

Every `WindowProxy`<sup>p934</sup> object has a `[[Window]]` internal slot representing the wrapped `Window`<sup>p922</sup> object.

#### Note

*Although `WindowProxy`<sup>p934</sup> is named as a "proxy", it does not do polymorphic dispatch on its target's internal methods as a real proxy would, due to a desire to reuse machinery between `WindowProxy`<sup>p934</sup> and `Location`<sup>p937</sup> objects. As long as the `Window`<sup>p922</sup> object remains an ordinary object this is unobservable and can be implemented either way.*

#### 7.2.3.1 `[[GetPrototypeOf]]` ( ) § p934

1. Let *W* be the value of the `[[Window]]`<sup>p934</sup> internal slot of **this**.
2. If `IsPlatformObjectSameOrigin`<sup>p920</sup>(*W*) is true, then return ! `OrdinaryGetPrototypeOf`(*W*).
3. Return null.

#### 7.2.3.2 `[[SetPrototypeOf]]` ( *V* ) § p934

1. Return ! `SetImmutablePrototype`(**this**, *V*).

#### 7.2.3.3 `[[IsExtensible]]` ( ) § p934

1. Return true.

#### 7.2.3.4 `[[PreventExtensions]]` ( ) § p934

1. Return false.

#### 7.2.3.5 `[[GetOwnProperty]]` ( *P* ) § p934

1. Let *W* be the value of the `[[Window]]`<sup>p934</sup> internal slot of **this**.
2. If *P* is an `array index property name`, then:
  1. Let *index* be ! `ToUint32`(*P*).
  2. Let *children* be the `document-tree child navigables`<sup>p995</sup> of *W*'s `associated Document`<sup>p923</sup>.
  3. Let *value* be undefined.
  4. If *index* is less than *children*'s `size`, then:

1. [Sort](#) children in ascending order, with *navigableA* being less than *navigableB* if *navigableA*'s [container](#)<sup>p991</sup> was inserted into *W*'s [associated Document](#)<sup>p923</sup> earlier than *navigableB*'s [container](#)<sup>p991</sup> was.
2. Set *value* to *children[index]*'s [active WindowProxy](#)<sup>p989</sup>.
5. If *value* is undefined, then:
  1. If [IsPlatformObjectSameOrigin](#)<sup>p920</sup>(*W*) is true, then return undefined.
  2. Throw a ["SecurityError" DOMException](#).
6. Return [PropertyDescriptor](#){ [[Value]]: *value*, [[Writable]]: false, [[Enumerable]]: true, [[Configurable]]: true }.
3. If [IsPlatformObjectSameOrigin](#)<sup>p920</sup>(*W*) is true, then return ! [OrdinaryGetOwnProperty](#)(*W*, *P*).

#### Note

*This is a [willful violation](#)<sup>p28</sup> of the JavaScript specification's [invariants of the essential internal methods](#) to maintain compatibility with existing web content. See [tc39/ecma262 issue #672](#) for more information. [\[JAVASCRIPT\]](#)<sup>p1479</sup>*

4. Let *property* be [CrossOriginGetOwnPropertyHelper](#)<sup>p920</sup>(*W*, *P*).
5. If *property* is not undefined, then return *property*.
6. If *property* is undefined and *P* is in *W*'s [document-tree child navigable target name property set](#)<sup>p929</sup>, then:
  1. Let *value* be the [active WindowProxy](#)<sup>p989</sup> of the [named object](#)<sup>p930</sup> of *W* with the name *P*.
  2. Return [PropertyDescriptor](#){ [[Value]]: *value*, [[Enumerable]]: false, [[Writable]]: false, [[Configurable]]: true }.

#### Note

*The reason the property descriptors are non-enumerable, despite this mismatching the same-origin behavior, is for compatibility with existing web content. See [issue #3183](#) for details.*

7. Return ? [CrossOriginPropertyFallback](#)<sup>p920</sup>(*P*).

### 7.2.3.6 [\[\[DefineOwnProperty\]\]](#) ( *P*, *Desc* ) § p93 5

1. Let *W* be the value of the [\[\[Window\]\]](#)<sup>p934</sup> internal slot of **this**.
2. If [IsPlatformObjectSameOrigin](#)<sup>p920</sup>(*W*) is true, then:
  1. If *P* is an [array index property name](#), return false.
  2. Return ? [OrdinaryDefineOwnProperty](#)(*W*, *P*, *Desc*).

#### Note

*This is a [willful violation](#)<sup>p28</sup> of the JavaScript specification's [invariants of the essential internal methods](#) to maintain compatibility with existing web content. See [tc39/ecma262 issue #672](#) for more information. [\[JAVASCRIPT\]](#)<sup>p1479</sup>*

3. Throw a ["SecurityError" DOMException](#).

### 7.2.3.7 [\[\[Get\]\]](#) ( *P*, *Receiver* ) § p93 5

1. Let *W* be the value of the [\[\[Window\]\]](#)<sup>p934</sup> internal slot of **this**.
2. [Check if an access between two browsing contexts should be reported](#)<sup>p908</sup>, given the [current global object](#)<sup>p1083</sup>'s [browsing context](#)<sup>p923</sup>, *W*'s [browsing context](#)<sup>p923</sup>, *P*, and the [current settings object](#)<sup>p1083</sup>.
3. If [IsPlatformObjectSameOrigin](#)<sup>p920</sup>(*W*) is true, then return ? [OrdinaryGet](#)(**this**, *P*, *Receiver*).

- Return ? [CrossOriginGet](#)<sup>p921</sup>(**this**, *P*, *Receiver*).

**Note**  
***this** is passed rather than *W* as [OrdinaryGet](#) and [CrossOriginGet](#)<sup>p921</sup> will invoke the [\[\[GetOwnProperty\]\]](#)<sup>p934</sup> internal method.*

#### 7.2.3.8 [\[\[Set\]\]](#) ( *P*, *V*, *Receiver* ) § p936

- Let *W* be the value of the [\[\[Window\]\]](#)<sup>p934</sup> internal slot of **this**.
- [Check if an access between two browsing contexts should be reported](#)<sup>p908</sup>, given the [current global object](#)<sup>p1083</sup>'s [browsing context](#)<sup>p998</sup>, *W*'s [browsing context](#)<sup>p998</sup>, *P*, and the [current settings object](#)<sup>p1083</sup>.
- If [IsPlatformObjectSameOrigin](#)<sup>p920</sup>(*W*) is true, then:
  - If *P* is an [array index property name](#), then return false.
  - Return ? [OrdinarySet](#)(*W*, *P*, *V*, *Receiver*).
- Return ? [CrossOriginSet](#)<sup>p922</sup>(**this**, *P*, *V*, *Receiver*).

**Note**  
***this** is passed rather than *W* as [CrossOriginSet](#)<sup>p922</sup> will invoke the [\[\[GetOwnProperty\]\]](#)<sup>p934</sup> internal method.*

#### 7.2.3.9 [\[\[Delete\]\]](#) ( *P* ) § p936

- Let *W* be the value of the [\[\[Window\]\]](#)<sup>p934</sup> internal slot of **this**.
- If [IsPlatformObjectSameOrigin](#)<sup>p920</sup>(*W*) is true, then:
  - If *P* is an [array index property name](#), then:
    - Let *desc* be ! **this**.[\[\[GetOwnProperty\]\]](#)(*P*).
    - If *desc* is undefined, then return true.
    - Return false.
  - Return ? [OrdinaryDelete](#)(*W*, *P*).
- Throw a ["SecurityError" DOMException](#).

#### 7.2.3.10 [\[\[OwnPropertyKeys\]\]](#) ( ) § p936

- Let *W* be the value of the [\[\[Window\]\]](#)<sup>p934</sup> internal slot of **this**.
- Let *maxProperties* be *W*'s [associated Document](#)<sup>p923</sup>'s [document-tree child navigables](#)<sup>p995</sup>'s [size](#).
- Let *keys* be [the range](#) 0 to *maxProperties*, exclusive.
- If [IsPlatformObjectSameOrigin](#)<sup>p920</sup>(*W*) is true, then return the concatenation of *keys* and [OrdinaryOwnPropertyKeys](#)(*W*).
- Return the concatenation of *keys* and ! [CrossOriginOwnPropertyKeys](#)<sup>p922</sup>(*W*).

#### 7.2.4 The [Location](#)<sup>p937</sup> interface § p936

Each [Window](#)<sup>p922</sup> object is associated with a unique instance of a [Location](#)<sup>p937</sup> object, allocated when the [Window](#)<sup>p922</sup> object is created.

### ⚠Warning!

**The [Location](#)<sup>p937</sup> exotic object is defined through a mishmash of IDL, invocation of JavaScript internal methods post-creation, and overridden JavaScript internal methods. Coupled with its scary security policy, please take extra care while implementing this excrescence.**

To create a [Location](#)<sup>p937</sup> object, run these steps:

1. Let *location* be a new [Location](#)<sup>p937</sup> platform object.
2. Let *valueOf* be *location*'s [relevant realm](#)<sup>p1083</sup>.[\[\[Intrinsics\]\].\[\[%Object.prototype.valueOf%\]\]](#).
3. Perform ! *location*.[\[\[DefineOwnProperty\]\]](#)("valueOf", { [\[\[Value\]\]](#): *valueOf*, [\[\[Writable\]\]](#): false, [\[\[Enumerable\]\]](#): false, [\[\[Configurable\]\]](#): false }).
4. Perform ! *location*.[\[\[DefineOwnProperty\]\]](#)([%Symbol.toPrimitive%](#)<sup>p57</sup>, { [\[\[Value\]\]](#): undefined, [\[\[Writable\]\]](#): false, [\[\[Enumerable\]\]](#): false, [\[\[Configurable\]\]](#): false }).
5. Set the value of the [\[\[DefaultProperties\]\]](#)<sup>p943</sup> internal slot of *location* to *location*.[\[\[OwnPropertyKeys\]\]](#)()
6. Return *location*.

### Note

The addition of *valueOf* and [%Symbol.toPrimitive%](#)<sup>p57</sup> own data properties, as well as the fact that all of [Location](#)<sup>p937</sup>'s IDL attributes are marked [\[LegacyUnforgeable\]](#), is required by legacy code that consulted the [Location](#)<sup>p937</sup> interface, or stringified it, to determine the [document URL](#), and then used it in a security-sensitive way. In particular, the *valueOf*, [%Symbol.toPrimitive%](#)<sup>p57</sup>, and [\[LegacyUnforgeable\]](#) stringifier mitigations ensure that code such as `foo[location] = bar` or `location + ""` cannot be misdirected.

### For web developers (non-normative)

**`document.location`<sup>p937</sup> [ = value ]**

**`window.location`<sup>p937</sup> [ = value ]**

Returns a [Location](#)<sup>p937</sup> object with the current page's location.

Can be set, to navigate to another page.

The [Document](#)<sup>p130</sup> object's **location** getter steps are to return [this](#)'s [relevant global object](#)<sup>p1083</sup>'s [Location](#)<sup>p937</sup> object, if [this](#) is [fully active](#)<sup>p1003</sup>, and null otherwise.

The [Window](#)<sup>p922</sup> object's **location** getter steps are to return [this](#)'s [Location](#)<sup>p937</sup> object.

[Location](#)<sup>p937</sup> objects provide a representation of the [URL](#) of their associated [Document](#)<sup>p130</sup>, as well as methods for [navigating](#)<sup>p1014</sup> and [reloading](#)<sup>p1027</sup> the associated [navigable](#)<sup>p989</sup>.

```
IDL [Exposed=Window]
interface Location { // but see also additional creation steps and overridden internal methods
  [LegacyUnforgeable] stringifier attribute USVString href;
  [LegacyUnforgeable] readonly attribute USVString origin;
  [LegacyUnforgeable] attribute USVString protocol;
  [LegacyUnforgeable] attribute USVString host;
  [LegacyUnforgeable] attribute USVString hostname;
  [LegacyUnforgeable] attribute USVString port;
  [LegacyUnforgeable] attribute USVString pathname;
  [LegacyUnforgeable] attribute USVString search;
  [LegacyUnforgeable] attribute USVString hash;

  [LegacyUnforgeable] undefined assign(USVString url);
  [LegacyUnforgeable] undefined replace(USVString url);
  [LegacyUnforgeable] undefined reload();

  [LegacyUnforgeable, SameObject] readonly attribute DOMStringList ancestorOrigins;
};
```

**`location.toString()`**

**`location.href`**<sup>p939</sup>

Returns the [Location](#)<sup>p937</sup> object's URL.

Can be set, to navigate to the given URL.

**`location.origin`**<sup>p939</sup>

Returns the [Location](#)<sup>p937</sup> object's URL's origin.

**`location.protocol`**<sup>p939</sup>

Returns the [Location](#)<sup>p937</sup> object's URL's scheme.

Can be set, to navigate to the same URL with a changed scheme.

**`location.host`**<sup>p940</sup>

Returns the [Location](#)<sup>p937</sup> object's URL's host and port (if different from the default port for the scheme).

Can be set, to navigate to the same URL with a changed host and port.

**`location.hostname`**<sup>p940</sup>

Returns the [Location](#)<sup>p937</sup> object's URL's host.

Can be set, to navigate to the same URL with a changed host.

**`location.port`**<sup>p940</sup>

Returns the [Location](#)<sup>p937</sup> object's URL's port.

Can be set, to navigate to the same URL with a changed port.

**`location.pathname`**<sup>p941</sup>

Returns the [Location](#)<sup>p937</sup> object's URL's path.

Can be set, to navigate to the same URL with a changed path.

**`location.search`**<sup>p941</sup>

Returns the [Location](#)<sup>p937</sup> object's URL's query (includes leading "?" if non-empty).

Can be set, to navigate to the same URL with a changed query (ignores leading "?").

**`location.hash`**<sup>p942</sup>

Returns the [Location](#)<sup>p937</sup> object's URL's fragment (includes leading "#" if non-empty).

Can be set, to navigate to the same URL with a changed fragment (ignores leading "#").

**`location.assign`**<sup>p942</sup> (*url*)

Navigates to the given URL.

**`location.replace`**<sup>p942</sup> (*url*)

Removes the current page from the session history and navigates to the given URL.

**`location.reload`**<sup>p942</sup> ()

Reloads the current page.

**`location.ancestorOrigins`**<sup>p943</sup>

Returns a [DOMStringList](#)<sup>p116</sup> object listing the origins of the [ancestor navigables](#)<sup>p994</sup>, [active documents](#)<sup>p989</sup>.

A [Location](#)<sup>p937</sup> object has an associated **relevant Document**, which is its [relevant global object](#)<sup>p1083</sup>'s [browsing context](#)<sup>p923</sup>'s [active document](#)<sup>p998</sup>, if this [Location](#)<sup>p937</sup> object's [relevant global object](#)<sup>p1083</sup>'s [browsing context](#)<sup>p923</sup> is non-null, and null otherwise.

A [Location](#)<sup>p937</sup> object has an associated **url**, which is this [Location](#)<sup>p937</sup> object's [relevant Document](#)<sup>p938</sup>'s **URL**, if this [Location](#)<sup>p937</sup> object's [relevant Document](#)<sup>p938</sup> is non-null, and [about:blank](#)<sup>p53</sup> otherwise.

A [Location](#)<sup>p937</sup> object has an associated **ancestor origins list**. When a [Location](#)<sup>p937</sup> object is created, its [ancestor origins list](#)<sup>p938</sup> must be set to a [DOMStringList](#)<sup>p116</sup> object whose associated list is the **list** of strings that the following steps would produce:

1. Let *output* be a new **list** of strings.
2. Let *current* be the [Location](#)<sup>p937</sup> object's [relevant Document](#)<sup>p938</sup>.
3. While *current*'s [container document](#)<sup>p992</sup> is non-null:

1. Set *current* to *current*'s [container document](#)<sup>p992</sup>.
2. [Append](#) the [serialization](#)<sup>p898</sup> of *current*'s [origin](#) to *output*.
4. Return *output*.

To **Location-object navigate** a [Location](#)<sup>p937</sup> object *location* to a [URL](#) *url*, optionally given a [NavigationHistoryBehavior](#)<sup>p952</sup> *historyHandling* (default "[auto](#)"<sup>p1014</sup>):

1. Let *navigable* be *location*'s [relevant global object](#)<sup>p1083</sup>'s [navigable](#)<sup>p923</sup>.
2. Let *sourceDocument* be the [incumbent global object](#)<sup>p1081</sup>'s [associated Document](#)<sup>p923</sup>.
3. If *location*'s [relevant Document](#)<sup>p938</sup> is not yet [completely loaded](#)<sup>p1063</sup>, and the [incumbent global object](#)<sup>p1081</sup> does not have [transient activation](#)<sup>p830</sup>, then set *historyHandling* to "[replace](#)"<sup>p1014</sup>.
4. [Navigate](#)<sup>p1014</sup> *navigable* to *url* using *sourceDocument*, with [exceptionsEnabled](#)<sup>p1014</sup> set to true and [historyHandling](#)<sup>p1014</sup> set to *historyHandling*.

The **href** getter steps are:

1. If *this*'s [relevant Document](#)<sup>p938</sup> is non-null and its [origin](#) is not [same origin-domain](#)<sup>p899</sup> with the [entry settings object](#)<sup>p1080</sup>'s [origin](#)<sup>p1076</sup>, then throw a "[SecurityError](#)" [DOMException](#).
2. Return *this*'s [url](#)<sup>p938</sup>, [serialized](#).

The **href**<sup>p939</sup> setter steps are:

1. If *this*'s [relevant Document](#)<sup>p938</sup> is null, then return.
2. Let *url* be the result of [encoding-parsing a URL](#)<sup>p97</sup> given the given value, relative to the [entry settings object](#)<sup>p1080</sup>.
3. If *url* is failure, then throw a "[SyntaxError](#)" [DOMException](#).
4. [Location-object navigate](#)<sup>p939</sup> *this* to *url*.

#### Note

The **href**<sup>p939</sup> setter intentionally has no security check.

The **origin** getter steps are:

1. If *this*'s [relevant Document](#)<sup>p938</sup> is non-null and its [origin](#) is not [same origin-domain](#)<sup>p899</sup> with the [entry settings object](#)<sup>p1080</sup>'s [origin](#)<sup>p1076</sup>, then throw a "[SecurityError](#)" [DOMException](#).
2. Return the [serialization](#)<sup>p898</sup> of *this*'s [url](#)<sup>p938</sup>'s [origin](#).

The **protocol** getter steps are:

1. If *this*'s [relevant Document](#)<sup>p938</sup> is non-null and its [origin](#) is not [same origin-domain](#)<sup>p899</sup> with the [entry settings object](#)<sup>p1080</sup>'s [origin](#)<sup>p1076</sup>, then throw a "[SecurityError](#)" [DOMException](#).
2. Return *this*'s [url](#)<sup>p938</sup>'s [scheme](#), followed by ":".

The **protocol**<sup>p939</sup> setter steps are:

1. If *this*'s [relevant Document](#)<sup>p938</sup> is null, then return.
2. If *this*'s [relevant Document](#)<sup>p938</sup>'s [origin](#) is not [same origin-domain](#)<sup>p899</sup> with the [entry settings object](#)<sup>p1080</sup>'s [origin](#)<sup>p1076</sup>, then throw a "[SecurityError](#)" [DOMException](#).
3. Let *copyURL* be a copy of *this*'s [url](#)<sup>p938</sup>.
4. Let *possibleFailure* be the result of [basic URL parsing](#) the given value, followed by ":", with *copyURL* as *url* and [scheme start state](#) as *state override*.

#### Note

Because the URL parser ignores multiple consecutive colons, providing a value of "https:" (or even "https:::") is the

same as providing a value of "https".

5. If *possibleFailure* is failure, then throw a ["SyntaxError" DOMException](#).
6. If *copyURL*'s [scheme](#) is not an [HTTP\(S\) scheme](#), then terminate these steps.
7. [Location-object navigate](#)<sup>p939</sup> *this* to *copyURL*.

The **host** getter steps are:

1. If *this*'s [relevant Document](#)<sup>p938</sup> is non-null and its [origin](#) is not [same origin-domain](#)<sup>p899</sup> with the [entry settings object](#)<sup>p1080</sup>'s [origin](#)<sup>p1076</sup>, then throw a ["SecurityError" DOMException](#).
2. Let *url* be *this*'s [url](#)<sup>p938</sup>.
3. If *url*'s [host](#) is null, return the empty string.
4. If *url*'s [port](#) is null, return *url*'s [host](#), [serialized](#).
5. Return *url*'s [host](#), [serialized](#), followed by ":" and *url*'s [port](#), [serialized](#).

The [host](#)<sup>p940</sup> setter steps are:

1. If *this*'s [relevant Document](#)<sup>p938</sup> is null, then return.
2. If *this*'s [relevant Document](#)<sup>p938</sup>'s [origin](#) is not [same origin-domain](#)<sup>p899</sup> with the [entry settings object](#)<sup>p1080</sup>'s [origin](#)<sup>p1076</sup>, then throw a ["SecurityError" DOMException](#).
3. Let *copyURL* be a copy of *this*'s [url](#)<sup>p938</sup>.
4. If *copyURL* has an [opaque path](#), then return.
5. [Basic URL parse](#) the given value, with *copyURL* as *url* and *host state* as *state override*.
6. [Location-object navigate](#)<sup>p939</sup> *this* to *copyURL*.

The **hostname** getter steps are:

1. If *this*'s [relevant Document](#)<sup>p938</sup> is non-null and its [origin](#) is not [same origin-domain](#)<sup>p899</sup> with the [entry settings object](#)<sup>p1080</sup>'s [origin](#)<sup>p1076</sup>, then throw a ["SecurityError" DOMException](#).
2. If *this*'s [url](#)<sup>p938</sup>'s [host](#) is null, return the empty string.
3. Return *this*'s [url](#)<sup>p938</sup>'s [host](#), [serialized](#).

The [hostname](#)<sup>p940</sup> setter steps are:

1. If *this*'s [relevant Document](#)<sup>p938</sup> is null, then return.
2. If *this*'s [relevant Document](#)<sup>p938</sup>'s [origin](#) is not [same origin-domain](#)<sup>p899</sup> with the [entry settings object](#)<sup>p1080</sup>'s [origin](#)<sup>p1076</sup>, then throw a ["SecurityError" DOMException](#).
3. Let *copyURL* be a copy of *this*'s [url](#)<sup>p938</sup>.
4. If *copyURL* has an [opaque path](#), then return.
5. [Basic URL parse](#) the given value, with *copyURL* as *url* and *hostname state* as *state override*.
6. [Location-object navigate](#)<sup>p939</sup> *this* to *copyURL*.

The **port** getter steps are:

1. If *this*'s [relevant Document](#)<sup>p938</sup> is non-null and its [origin](#) is not [same origin-domain](#)<sup>p899</sup> with the [entry settings object](#)<sup>p1080</sup>'s [origin](#)<sup>p1076</sup>, then throw a ["SecurityError" DOMException](#).
2. If *this*'s [url](#)<sup>p938</sup>'s [port](#) is null, return the empty string.
3. Return *this*'s [url](#)<sup>p938</sup>'s [port](#), [serialized](#).

The `port`<sup>p940</sup> setter steps are:

1. If `this`'s `relevant Document`<sup>p938</sup> is null, then return.
2. If `this`'s `relevant Document`<sup>p938</sup>'s `origin` is not `same origin-domain`<sup>p899</sup> with the `entry settings object`<sup>p1080</sup>'s `origin`<sup>p1076</sup>, then throw a `"SecurityError" DOMException`.
3. Let `copyURL` be a copy of `this`'s `url`<sup>p938</sup>.
4. If `copyURL` cannot have a username/password/port, then return.
5. If the given value is the empty string, then set `copyURL`'s `port` to null.
6. Otherwise, `basic URL parse` the given value, with `copyURL` as `url` and `port state` as `state override`.
7. `Location-object navigate`<sup>p939</sup> `this` to `copyURL`.

The `pathname` getter steps are:

1. If `this`'s `relevant Document`<sup>p938</sup> is non-null and its `origin` is not `same origin-domain`<sup>p899</sup> with the `entry settings object`<sup>p1080</sup>'s `origin`<sup>p1076</sup>, then throw a `"SecurityError" DOMException`.
2. Return the result of `URL path serializing` this `Location`<sup>p937</sup> object's `url`<sup>p938</sup>.

The `pathname`<sup>p941</sup> setter steps are:

1. If `this`'s `relevant Document`<sup>p938</sup> is null, then return.
2. If `this`'s `relevant Document`<sup>p938</sup>'s `origin` is not `same origin-domain`<sup>p899</sup> with the `entry settings object`<sup>p1080</sup>'s `origin`<sup>p1076</sup>, then throw a `"SecurityError" DOMException`.
3. Let `copyURL` be a copy of `this`'s `url`<sup>p938</sup>.
4. If `copyURL` has an `opaque path`, then return.
5. Set `copyURL`'s `path` to the empty list.
6. `Basic URL parse` the given value, with `copyURL` as `url` and `path start state` as `state override`.
7. `Location-object navigate`<sup>p939</sup> `this` to `copyURL`.

The `search` getter steps are:

1. If `this`'s `relevant Document`<sup>p938</sup> is non-null and its `origin` is not `same origin-domain`<sup>p899</sup> with the `entry settings object`<sup>p1080</sup>'s `origin`<sup>p1076</sup>, then throw a `"SecurityError" DOMException`.
2. If `this`'s `url`<sup>p938</sup>'s `query` is either null or the empty string, return the empty string.
3. Return "?", followed by `this`'s `url`<sup>p938</sup>'s `query`.

The `search`<sup>p941</sup> setter steps are:

1. If `this`'s `relevant Document`<sup>p938</sup> is null, then return.
2. If `this`'s `relevant Document`<sup>p938</sup>'s `origin` is not `same origin-domain`<sup>p899</sup> with the `entry settings object`<sup>p1080</sup>'s `origin`<sup>p1076</sup>, then throw a `"SecurityError" DOMException`.
3. Let `copyURL` be a copy of `this`'s `url`<sup>p938</sup>.
4. If the given value is the empty string, set `copyURL`'s `query` to null.
5. Otherwise, run these substeps:
  1. Let `input` be the given value with a single leading "?" removed, if any.
  2. Set `copyURL`'s `query` to the empty string.
  3. `Basic URL parse` `input`, with null, the `relevant Document`<sup>p938</sup>'s `document's character encoding`, `copyURL` as `url`, and `query state` as `state override`.
6. `Location-object navigate`<sup>p939</sup> `this` to `copyURL`.

The **hash** getter steps are:

1. If [this's relevant Document](#)<sup>p938</sup> is non-null and its [origin](#) is not [same origin-domain](#)<sup>p899</sup> with the [entry settings object](#)<sup>p1080</sup>'s [origin](#)<sup>p1076</sup>, then throw a ["SecurityError" DOMException](#).
2. If [this's url](#)<sup>p938</sup>'s [fragment](#) is either null or the empty string, return the empty string.
3. Return ["#"](#), followed by [this's url](#)<sup>p938</sup>'s [fragment](#).

The [hash](#)<sup>p942</sup> setter steps are:

1. If [this's relevant Document](#)<sup>p938</sup> is null, then return.
2. If [this's relevant Document](#)<sup>p938</sup>'s [origin](#) is not [same origin-domain](#)<sup>p899</sup> with the [entry settings object](#)<sup>p1080</sup>'s [origin](#)<sup>p1076</sup>, then throw a ["SecurityError" DOMException](#).
3. Let *copyURL* be a copy of [this's url](#)<sup>p938</sup>.
4. Let *input* be the given value with a single leading ["#"](#) removed, if any.
5. Set *copyURL*'s [fragment](#) to the empty string.
6. [Basic URL parse](#) *input*, with *copyURL* as [url](#) and [fragment state](#) as [state override](#).
7. If *copyURL*'s [fragment](#) is [this's url](#)<sup>p938</sup>'s [fragment](#), then return.

**Note**

*This bailout is necessary for compatibility with deployed content, which [redundantly sets location.hash on scroll](#). It does not apply to other mechanisms of fragment navigation, such as the [location.href](#)<sup>p939</sup> setter or [location.assign\(\)](#)<sup>p942</sup>.*

8. [Location-object navigate](#)<sup>p939</sup> [this](#) to *copyURL*.

**Note**

*Unlike the equivalent API for the [a](#)<sup>p257</sup> and [area](#)<sup>p471</sup> elements, the [hash](#)<sup>p942</sup> setter does not special case the empty string, to remain compatible with deployed scripts.*

The **assign(url)** method steps are:

1. If [this's relevant Document](#)<sup>p938</sup> is null, then return.
2. If [this's relevant Document](#)<sup>p938</sup>'s [origin](#) is not [same origin-domain](#)<sup>p899</sup> with the [entry settings object](#)<sup>p1080</sup>'s [origin](#)<sup>p1076</sup>, then throw a ["SecurityError" DOMException](#).
3. Let *urlRecord* be the result of [encoding-parsing a URL](#)<sup>p97</sup> given *url*, relative to the [entry settings object](#)<sup>p1080</sup>.
4. If *urlRecord* is failure, then throw a ["SyntaxError" DOMException](#).
5. [Location-object navigate](#)<sup>p939</sup> [this](#) to *urlRecord*.

The **replace(url)** method steps are:

1. If [this's relevant Document](#)<sup>p938</sup> is null, then return.
2. Let *urlRecord* be the result of [encoding-parsing a URL](#)<sup>p97</sup> given *url*, relative to the [entry settings object](#)<sup>p1080</sup>.
3. If *urlRecord* is failure, then throw a ["SyntaxError" DOMException](#).
4. [Location-object navigate](#)<sup>p939</sup> [this](#) to *urlRecord* given ["replace"](#)<sup>p1014</sup>.

**Note**

*The [replace\(\)](#)<sup>p942</sup> method intentionally has no security check.*

The **reload()** method steps are:

1. Let *document* be [this's relevant Document](#)<sup>p938</sup>.
2. If *document* is null, then return.
3. If *document*'s [origin](#) is not [same origin-domain](#)<sup>p899</sup> with the [entry settings object](#)<sup>p1080</sup>'s [origin](#)<sup>p1076</sup>, then throw a ["SecurityError" DOMException](#).
4. [Reload](#)<sup>p1027</sup> *document*'s [node navigable](#)<sup>p989</sup>.

The **ancestorOrigins** getter steps are:

1. If [this's relevant Document](#)<sup>p938</sup> is null, then return an empty [list](#).
2. If [this's relevant Document](#)<sup>p938</sup>'s [origin](#) is not [same origin-domain](#)<sup>p899</sup> with the [entry settings object](#)<sup>p1080</sup>'s [origin](#)<sup>p1076</sup>, then throw a ["SecurityError" DOMException](#).
3. Otherwise, return [this's ancestor origins list](#)<sup>p938</sup>.

#### ⚠Warning!

*The details of how the [ancestorOrigins](#)<sup>p943</sup> attribute works are still controversial and might change. See [issue #1918](#) for more information.*

As explained earlier, the [Location](#)<sup>p937</sup> exotic object requires additional logic beyond IDL for security purposes. The [Location](#)<sup>p937</sup> object must use the ordinary internal methods except where it is explicitly specified otherwise below.

Also, every [Location](#)<sup>p937</sup> object has a **[[DefaultProperties]]** internal slot representing its own properties at time of its creation.

#### 7.2.4.1 **[[GetPrototypeOf]]** ( ) § p94 3

1. If [IsPlatformObjectSameOrigin](#)<sup>p920</sup>(**this**) is true, then return ! [OrdinaryGetPrototypeOf](#)(**this**).
2. Return null.

#### 7.2.4.2 **[[SetPrototypeOf]]** ( V ) § p94 3

1. Return ! [SetImmutablePrototype](#)(**this**, V).

#### 7.2.4.3 **[[IsExtensible]]** ( ) § p94 3

1. Return true.

#### 7.2.4.4 **[[PreventExtensions]]** ( ) § p94 3

1. Return false.

#### 7.2.4.5 **[[GetOwnProperty]]** ( P ) § p94 3

1. If [IsPlatformObjectSameOrigin](#)<sup>p920</sup>(**this**) is true, then:
  1. Let *desc* be [OrdinaryGetOwnProperty](#)(**this**, P).
  2. If the value of the [\[\[DefaultProperties\]\]](#)<sup>p943</sup> internal slot of **this** contains P, then set *desc*.[[Configurable]] to true.
  3. Return *desc*.

2. Let *property* be [CrossOriginGetOwnPropertyHelper](#)<sup>p920</sup>(**this**, *P*).
3. If *property* is not undefined, then return *property*.
4. Return ? [CrossOriginPropertyFallback](#)<sup>p920</sup>(*P*).

#### 7.2.4.6 **[[DefineOwnProperty]]** ( *P*, *Desc* ) §<sup>p94</sup><sub>4</sub>

1. If [IsPlatformObjectSameOrigin](#)<sup>p920</sup>(**this**) is true, then:
  1. If the value of the [\[\[DefaultProperties\]\]](#)<sup>p943</sup> internal slot of **this** contains *P*, then return false.
  2. Return ? [OrdinaryDefineOwnProperty](#)(**this**, *P*, *Desc*).
2. Throw a ["SecurityError" DOMException](#).

#### 7.2.4.7 **[[Get]]** ( *P*, *Receiver* ) §<sup>p94</sup><sub>4</sub>

1. If [IsPlatformObjectSameOrigin](#)<sup>p920</sup>(**this**) is true, then return ? [OrdinaryGet](#)(**this**, *P*, *Receiver*).
2. Return ? [CrossOriginGet](#)<sup>p921</sup>(**this**, *P*, *Receiver*).

#### 7.2.4.8 **[[Set]]** ( *P*, *V*, *Receiver* ) §<sup>p94</sup><sub>4</sub>

1. If [IsPlatformObjectSameOrigin](#)<sup>p920</sup>(**this**) is true, then return ? [OrdinarySet](#)(**this**, *P*, *V*, *Receiver*).
2. Return ? [CrossOriginSet](#)<sup>p922</sup>(**this**, *P*, *V*, *Receiver*).

#### 7.2.4.9 **[[Delete]]** ( *P* ) §<sup>p94</sup><sub>4</sub>

1. If [IsPlatformObjectSameOrigin](#)<sup>p920</sup>(**this**) is true, then return ? [OrdinaryDelete](#)(**this**, *P*).
2. Throw a ["SecurityError" DOMException](#).

#### 7.2.4.10 **[[OwnPropertyKeys]]** ( ) §<sup>p94</sup><sub>4</sub>

1. If [IsPlatformObjectSameOrigin](#)<sup>p920</sup>(**this**) is true, then return [OrdinaryOwnPropertyKeys](#)(**this**).
2. Return [CrossOriginOwnPropertyKeys](#)<sup>p922</sup>(**this**).

### 7.2.5 The [History](#)<sup>p944</sup> interface §<sup>p94</sup><sub>4</sub>

```
IDL enum ScrollRestoration { "auto", "manual" };

[Exposed=Window]
interface History {
  readonly attribute unsigned long length;
  attribute ScrollRestoration scrollRestoration;
  readonly attribute any state;
  undefined go(optional long delta = 0);
  undefined back();
  undefined forward();
}
```

```
    undefined pushState(any data, DOMString unused, optional USVString? url = null);  
    undefined replaceState(any data, DOMString unused, optional USVString? url = null);  
};
```

For web developers (non-normative)

**history<sup>p945</sup>.length<sup>p946</sup>**

Returns the number of overall [session history entries<sup>p990</sup>](#) for the current [traversable navigable<sup>p990</sup>](#).

**history<sup>p945</sup>.scrollRestoration<sup>p946</sup>**

Returns the [scroll restoration mode<sup>p1005</sup>](#) of the [active session history entry<sup>p989</sup>](#).

**history<sup>p945</sup>.scrollRestoration<sup>p946</sup> = value**

Set the [scroll restoration mode<sup>p1005</sup>](#) of the [active session history entry<sup>p989</sup>](#) to *value*.

**history<sup>p945</sup>.state<sup>p946</sup>**

Returns the [classic history API state<sup>p1005</sup>](#) of the [active session history entry<sup>p989</sup>](#), deserialized into a JavaScript value.

**history<sup>p945</sup>.go<sup>p946</sup>( )**

Reloads the current page.

**history<sup>p945</sup>.go<sup>p946</sup>(delta)**

Goes back or forward the specified number of steps in the overall [session history entries<sup>p990</sup>](#) list for the current [traversable navigable<sup>p990</sup>](#).

A zero delta will reload the current page.

If the delta is out of range, does nothing.

**history<sup>p945</sup>.back<sup>p946</sup>( )**

Goes back one step in the overall [session history entries<sup>p990</sup>](#) list for the current [traversable navigable<sup>p990</sup>](#).

If there is no previous page, does nothing.

**history<sup>p945</sup>.forward<sup>p946</sup>( )**

Goes forward one step in the overall [session history entries<sup>p990</sup>](#) list for the current [traversable navigable<sup>p990</sup>](#).

If there is no next page, does nothing.

**history<sup>p945</sup>.pushState<sup>p946</sup>(data, "")**

Adds a new entry into session history with its [classic history API state<sup>p1005</sup>](#) set to a serialization of *data*. The [active history entry<sup>p989</sup>](#)'s [URL<sup>p1005</sup>](#) will be copied over and used for the new entry's URL.

(The second parameter exists for historical reasons, and cannot be omitted; passing the empty string is traditional.)

**history<sup>p945</sup>.pushState<sup>p946</sup>(data, "", url)**

Adds a new entry into session history with its [classic history API state<sup>p1005</sup>](#) set to a serialization of *data*, and with its [URL<sup>p1005</sup>](#) set to *url*.

If the current [Document<sup>p130</sup>](#) cannot have its URL rewritten<sup>p947</sup> to *url*, a "SecurityError" [DOMException](#) will be thrown.

(The second parameter exists for historical reasons, and cannot be omitted; passing the empty string is traditional.)

**history<sup>p945</sup>.replaceState<sup>p946</sup>(data, "")**

Updates the [classic history API state<sup>p1005</sup>](#) of the [active session history entry<sup>p989</sup>](#) to a structured clone of *data*.

(The second parameter exists for historical reasons, and cannot be omitted; passing the empty string is traditional.)

**history<sup>p945</sup>.replaceState<sup>p946</sup>(data, "", url)**

Updates the [classic history API state<sup>p1005</sup>](#) of the [active session history entry<sup>p989</sup>](#) to a structured clone of *data*, and its [URL<sup>p1005</sup>](#) to *url*.

If the current [Document<sup>p130</sup>](#) cannot have its URL rewritten<sup>p947</sup> to *url*, a "SecurityError" [DOMException](#) will be thrown.

(The second parameter exists for historical reasons, and cannot be omitted; passing the empty string is traditional.)

A [Document<sup>p130</sup>](#) has a **history object**, a [History<sup>p944</sup>](#) object.

The **history** getter steps are to return [this](#)'s [associated Document<sup>p923</sup>](#)'s [history object<sup>p945</sup>](#).

Each [History](#)<sup>p944</sup> object has **state**, initially null.

Each [History](#)<sup>p944</sup> object has a **length**, a non-negative integer, initially 0.

Each [History](#)<sup>p944</sup> object has an **index**, a non-negative integer, initially 0.

#### Note

*Although the [index](#)<sup>p946</sup> is not directly exposed, it can be inferred from changes to the [length](#)<sup>p946</sup> during synchronous navigations. In fact, that is what it's used for.*

The **length** getter steps are:

1. If [this](#)'s [relevant global object](#)<sup>p1083</sup>'s [associated Document](#)<sup>p923</sup> is not [fully active](#)<sup>p1003</sup>, then throw a ["SecurityError" DOMException](#).
2. Return [this](#)'s [length](#)<sup>p946</sup>.

The **scrollRestoration** getter steps are:

1. If [this](#)'s [relevant global object](#)<sup>p1083</sup>'s [associated Document](#)<sup>p923</sup> is not [fully active](#)<sup>p1003</sup>, then throw a ["SecurityError" DOMException](#).
2. Return [this](#)'s [node navigable](#)<sup>p989</sup>'s [active session history entry](#)<sup>p989</sup>'s [scroll restoration mode](#)<sup>p1005</sup>.

The **scrollRestoration**<sup>p946</sup> setter steps are:

1. If [this](#)'s [relevant global object](#)<sup>p1083</sup>'s [associated Document](#)<sup>p923</sup> is not [fully active](#)<sup>p1003</sup>, then throw a ["SecurityError" DOMException](#).
2. Set [this](#)'s [node navigable](#)<sup>p989</sup>'s [active session history entry](#)<sup>p989</sup>'s [scroll restoration mode](#)<sup>p1005</sup> to the given value.

The **state** getter steps are:

1. If [this](#)'s [relevant global object](#)<sup>p1083</sup>'s [associated Document](#)<sup>p923</sup> is not [fully active](#)<sup>p1003</sup>, then throw a ["SecurityError" DOMException](#).
2. Return [this](#)'s [state](#)<sup>p946</sup>.

The **go(delta)** method steps are to [delta traverse](#)<sup>p946</sup> [this](#) given *delta*.

The **back()** method steps are to [delta traverse](#)<sup>p946</sup> [this](#) given  $-1$ .

The **forward()** method steps are to [delta traverse](#)<sup>p946</sup> [this](#) given  $+1$ .

To **delta traverse** a [History](#)<sup>p944</sup> object *history* given an integer *delta*:

1. Let *document* be *history*'s [relevant global object](#)<sup>p1083</sup>'s [associated Document](#)<sup>p923</sup>.
2. If *document* is not [fully active](#)<sup>p1003</sup>, then throw a ["SecurityError" DOMException](#).
3. If *delta* is 0, then [reload](#)<sup>p1027</sup> *document*'s [node navigable](#)<sup>p989</sup>, and return.
4. [Traverse the history by a delta](#)<sup>p1028</sup> given *document*'s [node navigable](#)<sup>p989</sup>'s [traversable navigable](#)<sup>p990</sup>, *delta*, and with [sourceDocument](#)<sup>p1028</sup> set to *document*.

The **pushState(data, unused, url)** method steps are to run the [shared history push/replace state steps](#)<sup>p946</sup> given [this](#), *data*, *url*, and ["push"](#)<sup>p1014</sup>.

The **replaceState(data, unused, url)** method steps are to run the [shared history push/replace state steps](#)<sup>p946</sup> given [this](#), *data*, *url*, and ["replace"](#)<sup>p1014</sup>.

The **shared history push/replace state steps**, given a [History](#)<sup>p944</sup> *history*, a value *data*, a [scalar value string](#)-or-null *url*, and a [history handling behavior](#)<sup>p1014</sup> *historyHandling*, are:

1. Let *document* be *history*'s associated [Document](#)<sup>p130</sup>.

2. If *document* is not [fully active](#)<sup>p1003</sup>, then throw a ["SecurityError" DOMException](#).
3. Optionally, return. (For example, the user agent might disallow calls to these methods that are invoked on a timer, or from event listeners that are not triggered in response to a clear user action, or that are invoked in rapid succession.)
4. Let *serializedData* be [StructuredSerializeForStorage](#)<sup>p122</sup>(*data*). Rethrow any exceptions.
5. Let *newURL* be *document*'s [URL](#).
6. If *url* is not null or the empty string, then:
  1. Set *newURL* to the result of [encoding-parsing a URL](#)<sup>p97</sup> given *url*, relative to the [relevant settings object](#)<sup>p1083</sup> of *history*.
  2. If *newURL* is failure, then throw a ["SecurityError" DOMException](#).
  3. If *document* [cannot have its URL rewritten](#)<sup>p947</sup> to *newURL*, then throw a ["SecurityError" DOMException](#).

#### Note

The special case for the empty string here is historical, and leads to different resulting URLs when comparing code such as `location.href = ""` (which performs URL parsing on the empty string) versus `history.pushState(null, "", "")` (which bypasses it).

7. Let *navigation* be *history*'s [relevant global object](#)<sup>p1083</sup>'s [navigation API](#)<sup>p952</sup>.
8. Let *continue* be the result of [firing a push/replace/reload navigate event](#)<sup>p974</sup> at *navigation* with [navigationType](#)<sup>p974</sup> set to *historyHandling*, [isSameDocument](#)<sup>p974</sup> set to true, [destinationURL](#)<sup>p974</sup> set to *newURL*, and [classicHistoryAPIState](#)<sup>p975</sup> set to *serializedData*.
9. If *continue* is false, then return.
10. Run the [URL and history update steps](#)<sup>p1028</sup> given *document* and *newURL*, with [serializedData](#)<sup>p1028</sup> set to *serializedData* and [historyHandling](#)<sup>p1028</sup> set to *historyHandling*.

User agents may limit the number of state objects added to the session history per page. If a page hits the [implementation-defined](#) limit, user agents must remove the entry immediately after the first entry for that [Document](#)<sup>p130</sup> object in the session history after having added the new entry. (Thus the state history acts as a FIFO buffer for eviction, but as a LIFO buffer for navigation.)

A [Document](#)<sup>p130</sup> *document* **can have its URL rewritten** to a [URL](#) *targetURL* if the following algorithm returns true:

1. Let *documentURL* be *document*'s [URL](#).
2. If *targetURL* and *documentURL* differ in their [scheme](#), [username](#), [password](#), [host](#), or [port](#) components, then return false.
3. If *targetURL*'s [scheme](#) is an [HTTP\(S\) scheme](#), then return true.

#### Note

Differences in [path](#), [query](#), and [fragment](#) are allowed for [http:](#) and [https:](#) URLs.

4. If *targetURL*'s [scheme](#) is "file", then:
  1. If *targetURL* and *documentURL* differ in their [path](#) component, then return false.
  2. Return true.

#### Note

Differences in [query](#) and [fragment](#) are allowed for [file:](#) URLs.

5. If *targetURL* and *documentURL* differ in their [path](#) component or [query](#) components, then return false.

#### Note

Only differences in [fragment](#) are allowed for other types of URLs.

6. Return true.

#### Example

document's <a href="#">URL</a>	targetURL	can have its URL rewritten <sup>p947</sup>
https://example.com/home	https://example.com/home#about	✓
https://example.com/home	https://example.com/home?page=shop	✓
https://example.com/home	https://example.com/shop	✓
https://example.com/home	https://user:pass@example.com/home	✗
https://example.com/home	http://example.com/home	✗
file:///path/to/x	file:///path/to/x#hash	✓
file:///path/to/x	file:///path/to/x?search	✓
file:///path/to/x	file:///path/to/y	✗
about:blank	about:blank#hash	✓
about:blank	about:blank?search	✗
about:blank	about:srcdoc	✗
data:text/html,foo	data:text/html,foo#hash	✓
data:text/html,foo	data:text/html,foo?search	✗
data:text/html,foo	data:text/html,bar	✗
data:text/html,foo	data:bar	✗
blob:https://example.com/77becafe-657b-4fdc-8bd3-e83aaa5e8f43	blob:https://example.com/77becafe-657b-4fdc-8bd3-e83aaa5e8f43#hash	✓
blob:https://example.com/77becafe-657b-4fdc-8bd3-e83aaa5e8f43	blob:https://example.com/77becafe-657b-4fdc-8bd3-e83aaa5e8f43?search	✗
blob:https://example.com/77becafe-657b-4fdc-8bd3-e83aaa5e8f43	blob:https://example.com/anything	✗
blob:https://example.com/77becafe-657b-4fdc-8bd3-e83aaa5e8f43	blob:path	✗

Note how only the [URL](#) of the [Document](#)<sup>p130</sup> matters, and not its [origin](#). They can mismatch in cases like [about:blank](#)<sup>p53</sup> [Document](#)<sup>p130</sup>s with inherited origins, in sandboxed [iframe](#)<sup>p390</sup>s, or when the [document.domain](#)<sup>p901</sup> setter has been used.

### Example

Consider a game where the user can navigate along a line, such that the user is always at some coordinate, and such that the user can bookmark the page corresponding to a particular coordinate, to return to it later.

A static page implementing the x=5 position in such a game could look like the following:

```
<!DOCTYPE HTML>
<!-- this is https://example.com/line?x=5 -->
<html lang="en">
<title>Line Game - 5</title>
<p>You are at coordinate 5 on the line.</p>
<p>
  <a href="?x=6">Advance to 6</a> or
  <a href="?x=4">retreat to 4</a>?
</p>
```

The problem with such a system is that each time the user clicks, the whole page has to be reloaded. Here instead is another way of doing it, using script:

```
<!DOCTYPE HTML>
<!-- this starts off as https://example.com/line?x=5 -->
<html lang="en">
<title>Line Game - 5</title>
<p>You are at coordinate <span id="coord">5</span> on the line.</p>
<p>
  <a href="?x=6" onclick="go(1); return false;">Advance to 6</a> or
  <a href="?x=4" onclick="go(-1); return false;">retreat to 4</a>?
</p>
<script>
```

```

var currentPage = 5; // prefilled by server
function go(d) {
  setupPage(currentPage + d);
  history.pushState(currentPage, "", '?x=' + currentPage);
}
onpopstate = function(event) {
  setupPage(event.state);
}
function setupPage(page) {
  currentPage = page;
  document.title = 'Line Game - ' + currentPage;
  document.getElementById('coord').textContent = currentPage;
  document.links[0].href = '?x=' + (currentPage+1);
  document.links[0].textContent = 'Advance to ' + (currentPage+1);
  document.links[1].href = '?x=' + (currentPage-1);
  document.links[1].textContent = 'retreat to ' + (currentPage-1);
}
</script>

```

In systems without script, this still works like the previous example. However, users that *do* have script support can now navigate much faster, since there is no network access for the same experience. Furthermore, contrary to the experience the user would have with just a naïve script-based approach, bookmarking and navigating the session history still work.

In the example above, the *data* argument to the `pushState()`<sup>p946</sup> method is the same information as would be sent to the server, but in a more convenient form, so that the script doesn't have to parse the URL each time the user navigates.

### Example

Most applications want to use the same `scroll restoration mode`<sup>p1006</sup> value for all of their history entries. To achieve this they can set the `scrollRestoration`<sup>p946</sup> attribute as soon as possible (e.g., in the first `script`<sup>p652</sup> element in the document's `head`<sup>p173</sup> element) to ensure that any entry added to the history session gets the desired scroll restoration mode.

```

<head>
  <script>
    if ('scrollRestoration' in history)
      history.scrollRestoration = 'manual';
  </script>
</head>

```

## 7.2.6 The navigation API §<sup>p94</sup><sub>9</sub>

### 7.2.6.1 Introduction §<sup>p94</sup><sub>9</sub>

*This section is non-normative.*

The navigation API, provided by the global `navigation`<sup>p952</sup> property, provides a modern and web application-focused way of managing navigations and history entries. It is a successor to the classic `location`<sup>p937</sup> and `history`<sup>p945</sup> APIs.

One ability the API provides is inspecting `session history entries`<sup>p1005</sup>. For example, the following will display the entries' URLs in an ordered list:

```

const ol = document.createElement("ol");
ol.start = 0; // so that the list items' ordinal values match up with the entry indices

for (const entry of navigation.entries()) {
  const li = document.createElement("li");

```

```

if (entry.index < navigation.currentEntry.index) {
  li.className = "backward";
} else if (entry.index > navigation.currentEntry.index) {
  li.className = "forward";
} else {
  li.className = "current";
}

li.textContent = entry.url;
ol.append(li);
}

```

The `navigation.entries()`<sup>p958</sup> array contains `NavigationHistoryEntry`<sup>p956</sup> instances, which have other useful properties in addition to the `url`<sup>p957</sup> and `index`<sup>p957</sup> properties shown here. Note that the array only contains `NavigationHistoryEntry`<sup>p956</sup> objects that represent the current `navigable`<sup>p989</sup>, and thus its contents are not impacted by navigations inside `navigable containers`<sup>p991</sup> such as `iframe`<sup>p390</sup>s, or by navigations of the `parent navigable`<sup>p989</sup> in cases where the navigation API is itself being used inside an `iframe`<sup>p390</sup>. Additionally, it only contains `NavigationHistoryEntry`<sup>p956</sup> objects representing same-origin<sup>p898</sup> `session history entries`<sup>p1005</sup>, meaning that if the user has visited other origins before or after the current one, there will not be corresponding `NavigationHistoryEntry`<sup>p956</sup>s.

The navigation API can also be used to navigate, reload, or traverse through the history:

```

<button onclick="navigation.reload()">Reload</button>

<input type="url" id="navigationURL">
<button onclick="navigation.navigate(navigationURL.value)">Navigate</button>

<button id="backButton" onclick="navigation.back()">Back</button>
<button id="forwardButton" onclick="navigation.forward()">Forward</button>

<select id="traversalDestinations"></select>
<button id="goButton" onclick="navigation.traverseTo(traversalDestinations.value)">Traverse To</button>

<script>
backButton.disabled = !navigation.canGoBack;
forwardButton.disabled = !navigation.canGoForward;

for (const entry of navigation.entries()) {
  traversalDestinations.append(new Option(entry.url, entry.key));
}
</script>

```

Note that traversals are again limited to same-origin<sup>p898</sup> destinations, meaning that, for example, `navigation.canGoBack`<sup>p959</sup> will be false if the previous `session history entry`<sup>p1005</sup> is for a page from another origin.

The most powerful part of the navigation API is the `navigate`<sup>p1472</sup> event, which fires whenever almost any navigation or traversal occurs in the current `navigable`<sup>p989</sup>:

```

navigation.onnavigate = event => {
  console.log(event.navigationType); // "push", "replace", "reload", or "traverse"
  console.log(event.destination.url);
  console.log(event.userInitiated);
  // ... and other useful properties
};

```

(The event will not fire for `location bar-initiated navigations`<sup>p1069</sup>, or navigations initiated from other windows, when the destination of the navigation is a new document.)

Much of the time, the event's `cancelable` property will be true, meaning this event can be canceled using `preventDefault()`:

```

navigation.onnavigate = event => {
  if (event.cancelable && isDisallowedURL(event.destination.url)) {
    alert(`Please don't go to ${event.destination.url}!`);
    event.preventDefault();
  }
};

```

The `cancelable` property will be false for some "[traverse](#)<sup>p954</sup>" navigations, such as those taking place inside [child navigables](#)<sup>p992</sup>, those crossing to new origins, or when the user attempts to traverse again shortly after a previous call to `preventDefault()` prevented them from doing so.

The [NavigateEvent](#)<sup>p970</sup>'s `intercept()`<sup>p972</sup> method allows intercepting a navigation and converting it into a same-document navigation:

```

navigation.addEventListener("navigate", e => {
  // Some navigations, e.g. cross-origin navigations, we cannot intercept.
  // Let the browser handle those normally.
  if (!e.canIntercept) {
    return;
  }

  // Similarly, don't intercept fragment navigations or downloads.
  if (e.hashChange || e.downloadRequest !== null) {
    return;
  }

  const url = new URL(event.destination.url);

  if (url.pathname.startsWith("/articles/")) {
    e.intercept({
      async handler() {
        // The URL has already changed, so show a placeholder while
        // fetching the new content, such as a spinner or loading page.
        renderArticlePagePlaceholder();

        // Fetch the new content and display when ready.
        const articleContent = await getArticleContent(url.pathname, { signal: e.signal });
        renderArticlePage(articleContent);
      }
    });
  }
});

```

Note that the [handler](#)<sup>p970</sup> function can return a promise to represent the asynchronous progress, and success or failure, of the navigation. While the promise is still pending, browser UI can treat the navigation as ongoing (e.g., by presenting a loading spinner). Other parts of the navigation API are also sensitive to these promises, such as the return value of `navigation.navigate()`<sup>p960</sup>:

```

const { committed, finished } = await navigation.navigate("/articles/the-navigation-api-is-cool");

// The committed promise will fulfill once the URL has changed, which happens
// immediately (as long as the NavigateEvent wasn't canceled).
await committed;

// The finished promise will fulfill once the Promise returned by handler() has
// fulfilled, which happens once the article is downloaded and rendered. (Or,
// it will reject, if handler() fails along the way).
await finished;

```

## 7.2.6.2 The [Navigation](#)<sup>p952</sup> interface §<sup>p95</sup><sub>2</sub>

```
IDL [Exposed=Window]
interface Navigation : EventTarget {
  sequence<NavigationHistoryEntry> entries();
  readonly attribute NavigationHistoryEntry? currentEntry;
  undefined updateCurrentEntry(NavigationUpdateCurrentEntryOptions options);
  readonly attribute NavigationTransition? transition;
  readonly attribute NavigationActivation? activation;

  readonly attribute boolean canGoBack;
  readonly attribute boolean canGoForward;

  NavigationResult navigate(USVString url, optional NavigationNavigateOptions options = {});
  NavigationResult reload(optional NavigationReloadOptions options = {});

  NavigationResult traverseTo(DOMString key, optional NavigationOptions options = {});
  NavigationResult back(optional NavigationOptions options = {});
  NavigationResult forward(optional NavigationOptions options = {});

  attribute EventHandler onnavigate;
  attribute EventHandler onnavigatesuccess;
  attribute EventHandler onnavigateerror;
  attribute EventHandler oncurrententrychange;
};

dictionary NavigationUpdateCurrentEntryOptions {
  required any state;
};

dictionary NavigationOptions {
  any info;
};

dictionary NavigationNavigateOptions : NavigationOptions {
  any state;
  NavigationHistoryBehavior history = "auto";
};

dictionary NavigationReloadOptions : NavigationOptions {
  any state;
};

dictionary NavigationResult {
  Promise<NavigationHistoryEntry> committed;
  Promise<NavigationHistoryEntry> finished;
};

enum NavigationHistoryBehavior {
  "auto",
  "push",
  "replace"
};
```

Each [Window](#)<sup>p922</sup> has an associated **navigation API**, which is a [Navigation](#)<sup>p952</sup> object. Upon creation of the [Window](#)<sup>p922</sup> object, its [navigation API](#)<sup>p952</sup> must be set to a [new Navigation](#)<sup>p952</sup> object created in the [Window](#)<sup>p922</sup> object's [relevant realm](#)<sup>p1083</sup>.

The **navigation** getter steps are to return [this's navigation API](#)<sup>p952</sup>.

The following are the [event handlers](#)<sup>p1136</sup> (and their corresponding [event handler event types](#)<sup>p1139</sup>) that must be supported, as [event handler IDL attributes](#)<sup>p1137</sup>, by all objects implementing the [Navigation](#)<sup>p952</sup> interface:

Event handler <sup>p1136</sup>	Event handler event type <sup>p1139</sup>
onnavigate	navigate <sup>p1472</sup>
onnavigate success	navigate success <sup>p1472</sup>
onnavigate error	navigate error <sup>p1472</sup>
oncurrententrychange	currententrychange <sup>p1471</sup>

### 7.2.6.3 Core infrastructure <sup>§<sub>3</sub> p95</sup>

Each [Navigation](#)<sup>p952</sup> has an associated **entry list**, a **list** of [NavigationHistoryEntry](#)<sup>p956</sup> objects, initially empty.

Each [Navigation](#)<sup>p952</sup> has an associated **current entry index**, an integer, initially  $-1$ .

The **current entry** of a [Navigation](#)<sup>p952</sup> *navigation* is the result of running the following steps:

1. If *navigation* [has entries and events disabled](#)<sup>p953</sup>, then return null.
2. **Assert**: *navigation*'s [current entry index](#)<sup>p953</sup> is not  $-1$ .
3. Return *navigation*'s [entry list](#)<sup>p953</sup>[*navigation*'s [current entry index](#)<sup>p953</sup>].

A [Navigation](#)<sup>p952</sup> *navigation* **has entries and events disabled** if the following steps return true:

1. Let *document* be *navigation*'s [relevant global object](#)<sup>p1083</sup>'s [associated Document](#)<sup>p923</sup>.
2. If *document* is not [fully active](#)<sup>p1003</sup>, then return true.
3. If *document*'s [is initial about:blank](#)<sup>p131</sup> is true, then return true.
4. If *document*'s [origin](#) is [opaque](#)<sup>p898</sup>, then return true.
5. Return false.

To **get the navigation API entry index** of a [session history entry](#)<sup>p1005</sup> *she* within a [Navigation](#)<sup>p952</sup> *navigation*:

1. Let *index* be 0.
2. **For each** *nhe* of *navigation*'s [entry list](#)<sup>p953</sup>:
  1. If *nhe*'s [session history entry](#)<sup>p957</sup> is equal to *she*, then return *index*.
  2. Increment *index* by 1.
3. Return  $-1$ .

A key type used throughout the navigation API is the [NavigationType](#)<sup>p953</sup> enumeration:

```
IDL
enum NavigationType {
    "push",
    "replace",
    "reload",
    "traverse"
};
```

This captures the main web developer-visible types of "navigations", which (as [noted elsewhere](#)<sup>p1012</sup>) do not exactly correspond to this standard's singular [navigate](#)<sup>p1014</sup> algorithm. The meaning of each value is the following:

#### "push"

Corresponds to calls to [navigate](#)<sup>p1014</sup> where the [history handling behavior](#)<sup>p1014</sup> ends up as ["push"](#)<sup>p1014</sup>, or to [history.pushState\(\)](#)<sup>p946</sup>.

#### "replace"

Corresponds to calls to [navigate](#)<sup>p1014</sup> where the [history handling behavior](#)<sup>p1014</sup> ends up as ["replace"](#)<sup>p1014</sup>, or to

[history.replaceState\(\)](#)<sup>p946</sup>.

#### "reload"

Corresponds to calls to [reload](#)<sup>p1027</sup>.

#### "traverse"

Corresponds to calls to [traverse the history by a delta](#)<sup>p1028</sup>.

#### Note

The value space of the [NavigationType](#)<sup>p953</sup> enumeration is a superset of the value space of the specification-internal [history handling behavior](#)<sup>p1014</sup> type. Several parts of this standard make use of this overlap, by passing in a [history handling behavior](#)<sup>p1014</sup> to an algorithm that expects a [NavigationType](#)<sup>p953</sup>.

### 7.2.6.4 Initializing and updating the entry list <sup>p95</sup><sub>4</sub>

To **initialize the navigation API entries for a new document** given a [Navigation](#)<sup>p952</sup> navigation, a [list](#) of [session history entries](#)<sup>p1005</sup> newSHEs, and a [session history entry](#)<sup>p1005</sup> initialSHE:

1. [Assert](#): navigation's [entry list](#)<sup>p953</sup> is empty.
2. [Assert](#): navigation's [current entry index](#)<sup>p953</sup> is  $-1$ .
3. If navigation [has entries and events disabled](#)<sup>p953</sup>, then return.
4. [For each](#) newSHE of newSHEs:
  1. Let newNHE be a [new NavigationHistoryEntry](#)<sup>p956</sup> created in the [relevant realm](#)<sup>p1083</sup> of navigation.
  2. Set newNHE's [session history entry](#)<sup>p957</sup> to newSHE.
  3. [Append](#) newNHE to navigation's [entry list](#)<sup>p953</sup>.

#### Note

newSHEs will have originally come from [getting session history entries for the navigation API](#)<sup>p1011</sup>, and thus each newSHE will be contiguous [same](#)<sup>p899</sup> [origin](#)<sup>p1006</sup> with initialSHE.

5. Set navigation's [current entry index](#)<sup>p953</sup> to the result of [getting the navigation API entry index](#)<sup>p953</sup> of initialSHE within navigation.

To **update the navigation API entries for reactivation** given a [Navigation](#)<sup>p952</sup> navigation, a [list](#) of [session history entries](#)<sup>p1005</sup> newSHEs, and a [session history entry](#)<sup>p1005</sup> reactivatedSHE:

1. If navigation [has entries and events disabled](#)<sup>p953</sup>, then return.
2. Let newNHEs be a new empty [list](#).
3. Let oldNHEs be a [clone](#) of navigation's [entry list](#)<sup>p953</sup>.
4. [For each](#) newSHE of newSHEs:
  1. Let newNHE be null.
  2. If oldNHEs [contains](#) a [NavigationHistoryEntry](#)<sup>p956</sup> matchingOldNHE whose [session history entry](#)<sup>p957</sup> is newSHE, then:
    1. Set newNHE to matchingOldNHE.
    2. [Remove](#) matchingOldNHE from oldNHEs.
  3. Otherwise:
    1. Set newNHE to a [new NavigationHistoryEntry](#)<sup>p956</sup> created in the [relevant realm](#)<sup>p1083</sup> of navigation.
    2. Set newNHE's [session history entry](#)<sup>p957</sup> to newSHE.
4. [Append](#) newNHE to newNHEs.

**Note**

newSHEs will have originally come from [getting session history entries for the navigation API](#)<sup>p1011</sup>, and thus each newSHE will be contiguous [same](#)<sup>p899</sup> [origin](#)<sup>p1006</sup> with reactivatedSHE.

**Note**

By the end of this loop, all [NavigationHistoryEntry](#)<sup>p956</sup>s that remain in oldNHEs represent [session history entries](#)<sup>p1005</sup> which have been disposed while the [Document](#)<sup>p138</sup> was in [bfcache](#)<sup>p1006</sup>.

5. Set navigation's [entry list](#)<sup>p632</sup> to newNHEs.
6. Set navigation's [current entry index](#)<sup>p953</sup> to the result of [getting the navigation API entry index](#)<sup>p953</sup> of reactivatedSHE within navigation.
7. [Queue a global task](#)<sup>p1125</sup> on the [navigation and traversal task source](#)<sup>p1134</sup> given navigation's [relevant global object](#)<sup>p1083</sup> to run the following steps:
  1. [For each](#) disposedNHE of oldNHEs:
    1. [Fire an event](#) named [dispose](#)<sup>p1471</sup> at disposedNHE.

**Note**

We delay these steps by a task to ensure that [dispose](#)<sup>p1471</sup> events will fire after the [pageshow](#)<sup>p1472</sup> event. This ensures that [pageshow](#)<sup>p1472</sup> is the first event a page receives upon [reactivation](#)<sup>p1051</sup>.

(However, the rest of this algorithm runs before the [pageshow](#)<sup>p1472</sup> event fires. This ensures that [navigation.entries\(\)](#)<sup>p958</sup> and [navigation.currentEntry](#)<sup>p958</sup> will have correctly-updated values during any [pageshow](#)<sup>p1472</sup> event handlers.)

To **update the navigation API entries for a same-document navigation** given a [Navigation](#)<sup>p952</sup> navigation, a [session history entry](#)<sup>p1005</sup> destinationSHE, and a [NavigationType](#)<sup>p953</sup> navigationType:

1. If navigation [has entries and events disabled](#)<sup>p953</sup>, then return.
2. Let oldCurrentNHE be the [current entry](#)<sup>p953</sup> of navigation.
3. Let disposedNHEs be a new empty [list](#).
4. If navigationType is "[traverse](#)<sup>p954</sup>", then:
  1. Set navigation's [current entry index](#)<sup>p953</sup> to the result of [getting the navigation API entry index](#)<sup>p953</sup> of destinationSHE within navigation.
  2. [Assert](#): navigation's [current entry index](#)<sup>p953</sup> is not -1.

**Note**

This algorithm is only called for same-document traversals. Cross-document traversals will instead call either [initialize the navigation API entries for a new document](#)<sup>p954</sup> or [update the navigation API entries for reactivation](#)<sup>p954</sup>.

5. Otherwise, if navigationType is "[push](#)<sup>p953</sup>", then:
  1. Set navigation's [current entry index](#)<sup>p953</sup> to navigation's [current entry index](#)<sup>p953</sup> + 1.
  2. Let *i* be navigation's [current entry index](#)<sup>p953</sup>.
  3. [While](#) *i* < navigation's [entry list](#)<sup>p953</sup>'s [size](#):
    1. [Append](#) navigation's [entry list](#)<sup>p953</sup>[*i*] to disposedNHEs.
    2. Set *i* to *i* + 1.
  4. [Remove](#) all items in disposedNHEs from navigation's [entry list](#)<sup>p953</sup>.
6. Otherwise, if navigationType is "[replace](#)<sup>p953</sup>", then:
  1. [Append](#) oldCurrentNHE to disposedNHEs.
7. If navigationType is "[push](#)<sup>p953</sup>" or "[replace](#)<sup>p953</sup>", then:

1. Let *newNHE* be a [new `NavigationHistoryEntry`](#)<sup>p956</sup> created in the [relevant realm](#)<sup>p1083</sup> of navigation.
  2. Set *newNHE*'s [session history entry](#)<sup>p957</sup> to *destinationSHE*.
  3. Set navigation's [entry list](#)<sup>p953</sup>[navigation's [current entry index](#)<sup>p953</sup>] to *newNHE*.
8. If navigation's [ongoing API method tracker](#)<sup>p964</sup> is non-null, then [notify about the committed-to entry](#)<sup>p966</sup> given navigation's [ongoing API method tracker](#)<sup>p964</sup> and the [current entry](#)<sup>p953</sup> of navigation.

#### Note

*It is important to do this before firing the [dispose](#)<sup>p1471</sup> or [currententrychange](#)<sup>p1471</sup> events, since event handlers could start another navigation, or otherwise change the value of navigation's [ongoing API method tracker](#)<sup>p964</sup>.*

9. [Prepare to run script](#)<sup>p1097</sup> given navigation's [relevant settings object](#)<sup>p1083</sup>.

#### Note

*See [the discussion for other navigation API events](#)<sup>p977</sup> to understand why we do this.*

10. [Fire an event](#) named [currententrychange](#)<sup>p1471</sup> at navigation using [NavigationCurrentEntryChangeEvent](#)<sup>p980</sup>, with its [navigationType](#)<sup>p980</sup> attribute initialized to *navigationType* and its [from](#)<sup>p980</sup> initialized to *oldCurrentNHE*.
11. [For each](#) *disposedNHE* of *disposedNHEs*:
  1. [Fire an event](#) named [dispose](#)<sup>p1471</sup> at *disposedNHE*.
12. [Clean up after running script](#)<sup>p1097</sup> given navigation's [relevant settings object](#)<sup>p1083</sup>.

In implementations, same-document navigations can cause [session history entries](#)<sup>p1005</sup> to be disposed by falling off the back of the session history entry list. This is not yet handled by the above algorithm (or by any other part of this standard). See [issue #8620](#) to track progress on defining the correct behavior in such cases.

### 7.2.6.5 The [NavigationHistoryEntry](#)<sup>p956</sup> interface § <sup>p95</sup><sub>6</sub>

```
IDL [Exposed=Window]
interface NavigationHistoryEntry : EventTarget {
  readonly attribute USVString? url;
  readonly attribute DOMString key;
  readonly attribute DOMString id;
  readonly attribute long long index;
  readonly attribute boolean sameDocument;

  any getState();

  attribute EventHandler ondispose;
};
```

#### For web developers (non-normative)

##### [entry.url](#)<sup>p957</sup>

The URL of this navigation history entry.

This can return null if the entry corresponds to a different [Document](#)<sup>p130</sup> than the current one (i.e., if [sameDocument](#)<sup>p957</sup> is false), and that [Document](#)<sup>p130</sup> was fetched with a [referrer policy](#) of "no-referrer" or "origin", since that indicates the [Document](#)<sup>p130</sup> in question is hiding its URL even from other same-origin pages.

##### [entry.key](#)<sup>p957</sup>

A user agent-generated random UUID string representing this navigation history entry's place in the navigation history list. This value will be reused by other [NavigationHistoryEntry](#)<sup>p956</sup> instances that replace this one due to "[replace](#)<sup>p953</sup>" navigations, and will survive reloads and session restores.

This is useful for navigating back to this entry in the navigation history list, using [navigation.traverseTo\(key\)](#)<sup>p962</sup>.

### **entry.id**<sup>p957</sup>

A user agent-generated random UUID string representing this specific navigation history entry. This value will *not* be reused by other [NavigationHistoryEntry](#)<sup>p956</sup> instances. This value will survive reloads and session restores.

This is useful for associating data with this navigation history entry using other storage APIs.

### **entry.index**<sup>p957</sup>

The index of this [NavigationHistoryEntry](#)<sup>p956</sup> within [navigation.entries\(\)](#)<sup>p958</sup>, or  $-1$  if the entry is not in the navigation history entry list.

### **entry.sameDocument**<sup>p957</sup>

Indicates whether or not this navigation history entry is for the same [Document](#)<sup>p130</sup> as the current one, or not. This will be true, for example, when the entry represents a fragment navigation or single-page app navigation.

### **entry.getState**<sup>p958</sup> ()

Returns the [deserialization](#)<sup>p122</sup> of the state stored in this entry, which was added to the entry using [navigation.navigate\(\)](#)<sup>p960</sup> or [navigation.updateCurrentEntry\(\)](#)<sup>p958</sup>. This state survives reloads and session restores.

Note that in general, unless the state value is a primitive, `entry.getState() !== entry.getState()`, since a fresh deserialization is returned each time.

This state is unrelated to the classic history API's [history.state](#)<sup>p946</sup>.

Each [NavigationHistoryEntry](#)<sup>p956</sup> has an associated **session history entry**, which is a [session history entry](#)<sup>p1005</sup>.

The **key** of a [NavigationHistoryEntry](#)<sup>p956</sup> *nhe* is given by the return value of the following algorithm:

1. If *nhe*'s [relevant global object](#)<sup>p1083</sup>'s [associated Document](#)<sup>p923</sup> is not [fully active](#)<sup>p1003</sup>, then return the empty string.
2. Return *nhe*'s [session history entry](#)<sup>p957</sup>'s [navigation API key](#)<sup>p1005</sup>.

The **ID** of a [NavigationHistoryEntry](#)<sup>p956</sup> *nhe* is given by the return value of the following algorithm:

1. If *nhe*'s [relevant global object](#)<sup>p1083</sup>'s [associated Document](#)<sup>p923</sup> is not [fully active](#)<sup>p1003</sup>, then return the empty string.
2. Return *nhe*'s [session history entry](#)<sup>p957</sup>'s [navigation API ID](#)<sup>p1005</sup>.

The **index** of a [NavigationHistoryEntry](#)<sup>p956</sup> *nhe* is given by the return value of the following algorithm:

1. If *nhe*'s [relevant global object](#)<sup>p1083</sup>'s [associated Document](#)<sup>p923</sup> is not [fully active](#)<sup>p1003</sup>, then return  $-1$ .
2. Return the result of [getting the navigation API entry index](#)<sup>p953</sup> of *this*'s [session history entry](#)<sup>p957</sup> within *this*'s [relevant global object](#)<sup>p1083</sup>'s [navigation API](#)<sup>p952</sup>.

The **url** getter steps are:

1. Let *document* be *this*'s [relevant global object](#)<sup>p1083</sup>'s [associated Document](#)<sup>p923</sup>.
2. If *document* is not [fully active](#)<sup>p1003</sup>, then return the empty string.
3. Let *she* be *this*'s [session history entry](#)<sup>p957</sup>.
4. If *she*'s [document](#)<sup>p1005</sup> does not equal *document*, and *she*'s [document state](#)<sup>p1005</sup>'s [request referrer policy](#)<sup>p1006</sup> is "no-referrer" or "origin", then return null.
5. Return *she*'s [URL](#)<sup>p1005</sup>, [serialized](#).

The **key** getter steps are to return *this*'s [key](#)<sup>p957</sup>.

The **id** getter steps are to return *this*'s [ID](#)<sup>p957</sup>.

The **index** getter steps are to return *this*'s [index](#)<sup>p957</sup>.

The **sameDocument** getter steps are:

1. Let *document* be *this*'s [relevant global object](#)<sup>p1083</sup>'s [associated Document](#)<sup>p923</sup>.

2. If *document* is not [fully active](#)<sup>p1003</sup>, then return false.
3. Return true if *this*'s [session history entry](#)<sup>p957</sup>'s [document](#)<sup>p1005</sup> equals *document*, and false otherwise.

The **getState()** method steps are:

1. If *this*'s [relevant global object](#)<sup>p1083</sup>'s [associated Document](#)<sup>p923</sup> is not [fully active](#)<sup>p1003</sup>, then return undefined.
2. Return [StructuredDeserialize](#)<sup>p122</sup>(*this*'s [session history entry](#)<sup>p957</sup>'s [navigation API state](#)<sup>p1005</sup>). Rethrow any exceptions.

#### Note

*This can in theory throw an exception, if attempting to deserialize a large [ArrayBuffer](#) when not enough memory is available.*

The following are the [event handlers](#)<sup>p1136</sup> (and their corresponding [event handler event types](#)<sup>p1139</sup>) that must be supported, as [event handler IDL attributes](#)<sup>p1137</sup>, by all objects implementing the [NavigationHistoryEntry](#)<sup>p956</sup> interface:

<a href="#">Event handler</a> <sup>p1136</sup>	<a href="#">Event handler event type</a> <sup>p1139</sup>
<a href="#">ondispose</a>	<a href="#">dispose</a> <sup>p1471</sup>

### 7.2.6.6 The history entry list <sup>p95</sup><sub>8</sub>

For web developers (non-normative)

**[navigation](#)<sup>p952</sup>.[entries\(\)](#)**<sup>p958</sup>

Returns an array of [NavigationHistoryEntry](#)<sup>p956</sup> instances represent the current navigation history entry list, i.e., all [session history entries](#)<sup>p1005</sup> for this [navigable](#)<sup>p989</sup> that are [same origin](#)<sup>p899</sup> and contiguous to the [current session history entry](#)<sup>p989</sup>.

**[navigation](#)<sup>p952</sup>.[currentEntry](#)**<sup>p958</sup>

Returns the [NavigationHistoryEntry](#)<sup>p956</sup> corresponding to the [current session history entry](#)<sup>p989</sup>.

**[navigation](#)<sup>p952</sup>.[updateCurrentEntry](#)**<sup>p958</sup>(**state**<sup>p952</sup> )

Updates the [navigation API state](#)<sup>p1005</sup> of the [current session history entry](#)<sup>p989</sup>, without performing a navigation like [navigation.reload\(\)](#)<sup>p961</sup> would do.

This method is best used to capture updates to the page that have already happened, and need to be reflected into the navigation API state. For cases where the state update is meant to drive a page update, instead use [navigation.navigate\(\)](#)<sup>p960</sup> or [navigation.reload\(\)](#)<sup>p961</sup>, which will trigger a [navigate](#)<sup>p1472</sup> event.

**[navigation](#)<sup>p952</sup>.[canGoBack](#)**<sup>p959</sup>

Returns true if the current [current session history entry](#)<sup>p989</sup> (i.e., [currentEntry](#)<sup>p958</sup>) is not the first one in the navigation history entry list (i.e., in [entries\(\)](#)<sup>p958</sup>). This means that there is a previous [session history entry](#)<sup>p1005</sup> for this [navigable](#)<sup>p989</sup>, and its [document state](#)<sup>p1005</sup>'s [origin](#)<sup>p1006</sup> is [same origin](#)<sup>p899</sup> with the current [Document](#)<sup>p130</sup>'s [origin](#).

**[navigation](#)<sup>p952</sup>.[canGoForward](#)**<sup>p959</sup>

Returns true if the current [current session history entry](#)<sup>p989</sup> (i.e., [currentEntry](#)<sup>p958</sup>) is not the last one in the navigation history entry list (i.e., in [entries\(\)](#)<sup>p958</sup>). This means that there is a next [session history entry](#)<sup>p1005</sup> for this [navigable](#)<sup>p989</sup>, and its [document state](#)<sup>p1005</sup>'s [origin](#)<sup>p1006</sup> is [same origin](#)<sup>p899</sup> with the current [Document](#)<sup>p130</sup>'s [origin](#).

The **entries()** method steps are:

1. If *this* has [entries and events disabled](#)<sup>p953</sup>, then return the empty list.
2. Return *this*'s [entry list](#)<sup>p953</sup>.

#### Note

*Recall that because of Web IDL's sequence type conversion rules, this will create a new JavaScript array object on each call. That is, [navigation.entries\(\)](#)<sup>p958</sup> !== [navigation.entries\(\)](#)<sup>p958</sup>.*

The **currentEntry** getter steps are to return the [current entry](#)<sup>p953</sup> of *this*.

The **updateCurrentEntry(options)** method steps are:

1. Let *current* be the [current entry](#)<sup>p953</sup> of [this](#).
2. If *current* is null, then throw an ["InvalidStateError" DOMException](#).
3. Let *serializedState* be [StructuredSerializeForStorage](#)<sup>p122</sup>(*options*["[state](#)<sup>p952</sup>"]), rethrowing any exceptions.
4. Set *current*'s [session history entry](#)<sup>p957</sup>'s [navigation API state](#)<sup>p1005</sup> to *serializedState*.
5. [Fire an event](#) named [currententrychange](#)<sup>p1471</sup> at [this](#) using [NavigationCurrentEntryChangeEvent](#)<sup>p980</sup>, with its [navigationType](#)<sup>p980</sup> attribute initialized to null and its [from](#)<sup>p980</sup> initialized to *current*.

The **canGoBack** getter steps are:

1. If [this has entries and events disabled](#)<sup>p953</sup>, then return false.
2. [Assert](#): [this](#)'s [current entry index](#)<sup>p953</sup> is not −1.
3. If [this](#)'s [current entry index](#)<sup>p953</sup> is 0, then return false.
4. Return true.

The **canGoForward** getter steps are:

1. If [this has entries and events disabled](#)<sup>p953</sup>, then return false.
2. [Assert](#): [this](#)'s [current entry index](#)<sup>p953</sup> is not −1.
3. If [this](#)'s [current entry index](#)<sup>p953</sup> is equal to [this](#)'s [entry list](#)<sup>p953</sup>'s [size](#) − 1, then return false.
4. Return true.

#### 7.2.6.7 Initiating navigations §<sup>p95</sup><sub>9</sub>

For web developers (non-normative)

```
{ committedp952, finishedp952 } = navigationp952.navigatep960(url)
{ committedp952, finishedp952 } = navigationp952.navigatep960(url, options)
```

[Navigates](#)<sup>p1014</sup> the current page to the given *url*. *options* can contain the following values:

- [history](#)<sup>p952</sup> can be set to ["replace"](#)<sup>p1014</sup> to replace the current session history entry, instead of pushing a new one.
- [info](#)<sup>p952</sup> can be set to any value; it will populate the [info](#)<sup>p972</sup> property of the corresponding [NavigateEvent](#)<sup>p970</sup>.
- [state](#)<sup>p952</sup> can be set to any [serializable](#)<sup>p117</sup> value; it will populate the state retrieved by [navigation.currentEntry.getState\(\)](#)<sup>p958</sup> once the navigation completes, for same-document navigations. (It will be ignored for navigations that end up cross-document.)

By default this will perform a full navigation (i.e., a cross-document navigation, unless the given URL differs only in a [fragment](#) from the current one). The [navigateEvent.intercept\(\)](#)<sup>p972</sup> method can be used to convert it into a same-document navigation.

The returned promises will behave as follows:

- For navigations that get aborted, both promises will reject with an ["AbortError" DOMException](#).
- For same-document navigations created by using the [navigateEvent.intercept\(\)](#)<sup>p972</sup> method, [committed](#)<sup>p952</sup> will fulfill immediately, and [finished](#)<sup>p952</sup> will fulfill or reject according to any promises returned by handlers passed to [intercept\(\)](#)<sup>p972</sup>.
- For other same-document navigations (e.g., non-intercepted [fragment navigations](#)<sup>p1021</sup>), both promises will fulfill immediately.
- For cross-document navigations, or navigations that result in 204 or 205 [statuses](#) or `Content-Disposition: attachment` header fields from the server (and thus do not actually navigate), both promises will never settle.

In all cases, when the returned promises fulfill, it will be with the [NavigationHistoryEntry](#)<sup>p956</sup> that was navigated to.

```
{ committedp952, finishedp952 } = navigationp952.reloadp961(options)
```

[Reloads<sup>p1027</sup>](#) the current page. *options* can contain [info<sup>p952</sup>](#) and [state<sup>p952</sup>](#), which behave as described above.

The default behavior of performing a from-network-or-cache reload of the current page can be overridden by the using the [navigateEvent.intercept\(\)<sup>p972</sup>](#) method. Doing so will mean this call only updates state or passes along the appropriate [info<sup>p952</sup>](#), plus performing whatever actions the [navigate<sup>p1472</sup>](#) event handlers see fit to carry out.

The returned promises will behave as follows:

- If the reload is intercepted by using the [navigateEvent.intercept\(\)<sup>p972</sup>](#) method, [committed<sup>p952</sup>](#) will fulfill immediately, and [finished<sup>p952</sup>](#) will fulfill or reject according to any promises returned by handlers passed to [intercept\(\)<sup>p972</sup>](#).
- Otherwise, both promises will never settle.

```
{ committedp952, finishedp952 } = navigationp952.traverseTop962(key)
```

```
{ committedp952, finishedp952 } = navigationp952.traverseTop962(key, { infop952 })
```

[Traverses<sup>p1040</sup>](#) to the closest [session history entry<sup>p1005</sup>](#) that matches the [NavigationHistoryEntry<sup>p956</sup>](#) with the given key. [info<sup>p952</sup>](#) can be set to any value; it will populate the [info<sup>p972</sup>](#) property of the corresponding [NavigateEvent<sup>p978</sup>](#).

If a traversal to that [session history entry<sup>p1005</sup>](#) is already in progress, then this will return the promises for that original traversal, and [info<sup>p972</sup>](#) will be ignored.

The returned promises will behave as follows:

- If there is no [NavigationHistoryEntry<sup>p956</sup>](#) in [navigation.entries\(\)<sup>p958</sup>](#) whose [key<sup>p957</sup>](#) matches *key*, both promises will reject with an ["InvalidStateError" DOMException](#).
- For same-document traversals intercepted by the [navigateEvent.intercept\(\)<sup>p972</sup>](#) method, [committed<sup>p952</sup>](#) will fulfill as soon as the traversal is processed and [navigation.currentEntry<sup>p958</sup>](#) is updated, and [finished<sup>p952</sup>](#) will fulfill or reject according to any promises returned by the handlers passed to [intercept\(\)<sup>p972</sup>](#).
- For non-intercepted same-document traversals, both promises will fulfill as soon as the traversal is processed and [navigation.currentEntry<sup>p958</sup>](#) is updated.
- For cross-document traversals, including attempted cross-document traversals that end up resulting in a 204 or 205 [statuses](#) or ``Content-Disposition: attachment`` header fields from the server (and thus do not actually traverse), both promises will never settle.

```
{ committedp952, finishedp952 } = navigationp952.backp962(key)
```

```
{ committedp952, finishedp952 } = navigationp952.backp962(key, { infop952 })
```

Traverses to the closest previous [session history entry<sup>p1005</sup>](#) which results in this [navigable<sup>p989</sup>](#) traversing, i.e., which corresponds to a different [NavigationHistoryEntry<sup>p956</sup>](#) and thus will cause [navigation.currentEntry<sup>p958</sup>](#) to change. [info<sup>p952</sup>](#) can be set to any value; it will populate the [info<sup>p972</sup>](#) property of the corresponding [NavigateEvent<sup>p978</sup>](#).

If a traversal to that [session history entry<sup>p1005</sup>](#) is already in progress, then this will return the promises for that original traversal, and [info<sup>p972</sup>](#) will be ignored.

The returned promises behave equivalently to those returned by [traverseTo\(\)<sup>p962</sup>](#).

```
{ committedp952, finishedp952 } = navigationp952.forwardp962(key)
```

```
{ committedp952, finishedp952 } = navigationp952.forwardp962(key, { infop952 })
```

Traverses to the closest forward [session history entry<sup>p1005</sup>](#) which results in this [navigable<sup>p989</sup>](#) traversing, i.e., which corresponds to a different [NavigationHistoryEntry<sup>p956</sup>](#) and thus will cause [navigation.currentEntry<sup>p958</sup>](#) to change. [info<sup>p952</sup>](#) can be set to any value; it will populate the [info<sup>p972</sup>](#) property of the corresponding [NavigateEvent<sup>p978</sup>](#).

If a traversal to that [session history entry<sup>p1005</sup>](#) is already in progress, then this will return the promises for that original traversal, and [info<sup>p972</sup>](#) will be ignored.

The returned promises behave equivalently to those returned by [traverseTo\(\)<sup>p962</sup>](#).

The [navigate\(url, options\)](#) method steps are:

1. Let *urlRecord* be the result of [parsing a URL<sup>p97</sup>](#) given *url*, relative to [this's relevant settings object<sup>p1083</sup>](#).
2. If *urlRecord* is failure, then return an [early error result<sup>p963</sup>](#) for a ["SyntaxError" DOMException](#).
3. Let *document* be [this's relevant global object<sup>p1083</sup>](#)'s [associated Document<sup>p923</sup>](#).

4. If `options["history"p952]` is "`push`<sup>p1014</sup>", and `the navigation must be a replace`<sup>p1014</sup> given `urlRecord` and `document`, then return an `early error result`<sup>p963</sup> for a "`NotSupportedError`" `DOMException`.
5. Let `state` be `options["state"p952]`, if it `exists`; otherwise, undefined.
6. Let `serializedState` be `StructuredSerializeForStorage`<sup>p122</sup>(`state`). If this throws an exception, then return an `early error result`<sup>p963</sup> for that exception.

#### Note

*It is importantly to perform this step early, since serialization can invoke web developer code, which in turn might change various things we check in later steps.*

7. If `document` is not `fully active`<sup>p1003</sup>, then return an `early error result`<sup>p963</sup> for an "`InvalidStateError`" `DOMException`.
8. If `document`'s `unload counter`<sup>p1064</sup> is greater than 0, then return an `early error result`<sup>p963</sup> for an "`InvalidStateError`" `DOMException`.
9. Let `info` be `options["info"p952]`, if it `exists`; otherwise, undefined.
10. Let `apiMethodTracker` be the result of `maybe setting the upcoming non-traverse API method tracker`<sup>p964</sup> for `this` given `info` and `serializedState`.
11. `Navigate`<sup>p1014</sup> `document`'s `node navigable`<sup>p989</sup> to `urlRecord` using `document`, with `historyHandling`<sup>p1014</sup> set to `options["history"p952]` and `navigationAPIState`<sup>p1014</sup> set to `serializedState`.

#### Note

*Unlike `location.assign()`<sup>p942</sup> and friends, which are exposed across `origin-domain`<sup>p899</sup> boundaries, `navigation.navigate()`<sup>p968</sup> can only be accessed by code with direct synchronous access to the `window.navigation`<sup>p952</sup> property. Thus, we avoid the complications about attributing the source document of the navigation, and we don't need to deal with the `allowed by sandboxing to navigate`<sup>p1025</sup> check and its accompanying `exceptionsEnabled`<sup>p1014</sup> flag. We just treat all navigations as if they come from the `Document`<sup>p130</sup> corresponding to this `Navigation`<sup>p952</sup> object itself (i.e., `document`).*

12. If `this`'s `upcoming non-traverse API method tracker`<sup>p964</sup> is `apiMethodTracker`, then:

#### Note

*If the `upcoming non-traverse API method tracker`<sup>p964</sup> is still `apiMethodTracker`, this means that the `navigate`<sup>p1014</sup> algorithm bailed out before ever getting to the `inner navigate event firing algorithm`<sup>p975</sup> which would `promote that upcoming API method tracker to ongoing`<sup>p966</sup>.*

1. Set `this`'s `upcoming non-traverse API method tracker`<sup>p964</sup> to null.
  2. Return an `early error result`<sup>p963</sup> for an "`AbortError`" `DOMException`.
13. Return a `navigation API method tracker-derived result`<sup>p963</sup> for `apiMethodTracker`.

The `reload(options)` method steps are:

1. Let `document` be `this`'s `relevant global object`<sup>p1083</sup>'s `associated Document`<sup>p923</sup>.
2. Let `serializedState` be `StructuredSerializeForStorage`<sup>p122</sup>(undefined).
3. If `options["state"p952]` `exists`, then set `serializedState` to `StructuredSerializeForStorage`<sup>p122</sup>(`options["state"p952]`). If this throws an exception, then return an `early error result`<sup>p963</sup> for that exception.

#### Note

*It is importantly to perform this step early, since serialization can invoke web developer code, which in turn might change various things we check in later steps.*

4. Otherwise:
  1. Let `current` be the `current entry`<sup>p953</sup> of `this`.
  2. If `current` is not null, then set `serializedState` to `current`'s `session history entry`<sup>p957</sup>'s `navigation API state`<sup>p1005</sup>.
5. If `document` is not `fully active`<sup>p1003</sup>, then return an `early error result`<sup>p963</sup> for an "`InvalidStateError`" `DOMException`.

6. If *document*'s [unload counter](#)<sup>p1064</sup> is greater than 0, then return an [early error result](#)<sup>p963</sup> for an ["InvalidStateError"](#) [DOMException](#).
7. Let *info* be *options*["[info](#)<sup>p952</sup>"], if it [exists](#); otherwise, undefined.
8. Let *apiMethodTracker* be the result of [maybe setting the upcoming non-traverse API method tracker](#)<sup>p964</sup> for *this* given *info* and *serializedState*.
9. [Reload](#)<sup>p1027</sup> *document*'s [node navigable](#)<sup>p989</sup> with [navigationAPIState](#)<sup>p1027</sup> set to *serializedState*.
10. Return a [navigation API method tracker-derived result](#)<sup>p963</sup> for *apiMethodTracker*.

The **traverseTo(key, options)** method steps are:

1. If *this*'s [current entry index](#)<sup>p953</sup> is −1, then return an [early error result](#)<sup>p963</sup> for an ["InvalidStateError"](#) [DOMException](#).
2. If *this*'s [entry list](#)<sup>p953</sup> does not [contain](#) a [NavigationHistoryEntry](#)<sup>p956</sup> whose [session history entry](#)<sup>p957</sup>'s [navigation API key](#)<sup>p1005</sup> equals *key*, then return an [early error result](#)<sup>p963</sup> for an ["InvalidStateError"](#) [DOMException](#).
3. Return the result of [performing a navigation API traversal](#)<sup>p962</sup> given *this*, *key*, and *options*.

The **back(options)** method steps are:

1. If *this*'s [current entry index](#)<sup>p953</sup> is −1 or 0, then return an [early error result](#)<sup>p963</sup> for an ["InvalidStateError"](#) [DOMException](#).
2. Let *key* be *this*'s [entry list](#)<sup>p953</sup>[*this*'s [current entry index](#)<sup>p953</sup> − 1]'s [session history entry](#)<sup>p957</sup>'s [navigation API key](#)<sup>p1005</sup>.
3. Return the result of [performing a navigation API traversal](#)<sup>p962</sup> given *this*, *key*, and *options*.

The **forward(options)** method steps are:

1. If *this*'s [current entry index](#)<sup>p953</sup> is −1 or is equal to *this*'s [entry list](#)<sup>p953</sup>'s [size](#) − 1, then return an [early error result](#)<sup>p963</sup> for an ["InvalidStateError"](#) [DOMException](#).
2. Let *key* be *this*'s [entry list](#)<sup>p953</sup>[*this*'s [current entry index](#)<sup>p953</sup> + 1]'s [session history entry](#)<sup>p957</sup>'s [navigation API key](#)<sup>p1005</sup>.
3. Return the result of [performing a navigation API traversal](#)<sup>p962</sup> given *this*, *key*, and *options*.

To **perform a navigation API traversal** given a [Navigation](#)<sup>p952</sup> *navigation*, a string *key*, and a [NavigationOptions](#)<sup>p952</sup> *options*:

1. Let *document* be *navigation*'s [relevant global object](#)<sup>p1083</sup>'s [associated Document](#)<sup>p923</sup>.
2. If *document* is not [fully active](#)<sup>p1003</sup>, then return an [early error result](#)<sup>p963</sup> for an ["InvalidStateError"](#) [DOMException](#).
3. If *document*'s [unload counter](#)<sup>p1064</sup> is greater than 0, then return an [early error result](#)<sup>p963</sup> for an ["InvalidStateError"](#) [DOMException](#).
4. Let *current* be the [current entry](#)<sup>p953</sup> of *navigation*.
5. If *key* equals *current*'s [session history entry](#)<sup>p957</sup>'s [navigation API key](#)<sup>p1005</sup>, then return «[ "[committed](#)<sup>p952</sup>" → [a promise resolved with current](#), "[finished](#)<sup>p952</sup>" → [a promise resolved with current](#) ]».
6. If *navigation*'s [upcoming traverse API method trackers](#)<sup>p964</sup>[*key*] [exists](#), then return a [navigation API method tracker-derived result](#)<sup>p963</sup> for *navigation*'s [upcoming traverse API method trackers](#)<sup>p964</sup>[*key*].
7. Let *info* be *options*["[info](#)<sup>p952</sup>"], if it [exists](#); otherwise, undefined.
8. Let *apiMethodTracker* be the result of [adding an upcoming traverse API method tracker](#)<sup>p965</sup> for *navigation* given *key* and *info*.
9. Let *navigable* be *document*'s [node navigable](#)<sup>p989</sup>.
10. Let *traversable* be *navigable*'s [traversable navigable](#)<sup>p990</sup>.
11. Let *sourceSnapshotParams* be the result of [snapshotting source snapshot params](#)<sup>p1012</sup> given *document*.
12. [Append the following session history traversal steps](#)<sup>p1008</sup> to *traversable*:
  1. Let *navigableSHEs* be the result of [getting session history entries](#)<sup>p1010</sup> given *navigable*.
  2. Let *targetSHE* be the [session history entry](#)<sup>p1005</sup> in *navigableSHEs* whose [navigation API key](#)<sup>p1005</sup> is *key*. If no such

entry exists, then:

1. [Queue a global task](#)<sup>p1125</sup> on the [navigation and traversal task source](#)<sup>p1134</sup> given *navigation's relevant global object*<sup>p1083</sup> to [reject the finished promise](#)<sup>p967</sup> for *apiMethodTracker* with an ["InvalidStateError" DOMException](#).
2. Abort these steps.

#### Note

*This path is taken if *navigation's entry list*<sup>p953</sup> was outdated compared to navigableSHEs, which can occur for brief periods while all the relevant threads and processes are being synchronized in reaction to a history change.*

3. If *targetSHE* is *navigable's active session history entry*<sup>p989</sup>, then abort these steps.

#### Note

*This can occur if a previously [queued](#)<sup>p1008</sup> traversal already took us to this [session history entry](#)<sup>p1005</sup>. In that case the previous traversal will have dealt with *apiMethodTracker* already.*

4. Let *result* be the result of [applying the traverse history step](#)<sup>p1040</sup> given by *targetSHE's step*<sup>p1005</sup> to *traversable*, given *sourceSnapshotParams*, *navigable*, and ["none"](#)<sup>p1014</sup>.
5. If *result* is "canceled-by-beforeunload", then [queue a global task](#)<sup>p1125</sup> on the [navigation and traversal task source](#)<sup>p1134</sup> given *navigation's relevant global object*<sup>p1083</sup> to [reject the finished promise](#)<sup>p967</sup> for *apiMethodTracker* with a new ["AbortError" DOMException](#) created in *navigation's relevant realm*<sup>p1083</sup>.
6. If *result* is "initiator-disallowed", then [queue a global task](#)<sup>p1125</sup> on the [navigation and traversal task source](#)<sup>p1134</sup> given *navigation's relevant global object*<sup>p1083</sup> to [reject the finished promise](#)<sup>p967</sup> for *apiMethodTracker* with a new ["SecurityError" DOMException](#) created in *navigation's relevant realm*<sup>p1083</sup>.

#### Note

*When *result* is "canceled-by-beforeunload" or "initiator-disallowed", the [navigate](#)<sup>p1472</sup> event was never fired, [aborting the ongoing navigation](#)<sup>p967</sup> would not be correct; it would result in a [navigateerror](#)<sup>p1472</sup> event without a preceding [navigate](#)<sup>p1472</sup> event.*

*In the "canceled-by-navigate" case, [navigate](#)<sup>p1472</sup> is fired, but the [inner navigate event firing algorithm](#)<sup>p975</sup> will take care of [aborting the ongoing navigation](#)<sup>p967</sup>.*

13. Return a [navigation API method tracker-derived result](#)<sup>p963</sup> for *apiMethodTracker*.

An **early error result** for an exception *e* is a [NavigationResult](#)<sup>p952</sup> dictionary instance given by «[ ["committed"](#)<sup>p952</sup> → a [promise rejected with](#) *e*, ["finished"](#)<sup>p952</sup> → a [promise rejected with](#) *e* ]».

A **navigation API method tracker-derived result** for a [navigation API method tracker](#)<sup>p964</sup> is a [NavigationResult](#)<sup>p952</sup> dictionary instance given by «[ ["committed"](#)<sup>p952</sup> → *apiMethodTracker's committed promise*<sup>p964</sup>, ["finished"](#)<sup>p952</sup> → *apiMethodTracker's finished promise*<sup>p964</sup> ]».

### 7.2.6.8 Ongoing navigation tracking <sup>§<sup>p96</sup><sub>3</sub></sup>

During any given navigation (in the [broad sense of the word](#)<sup>p953</sup>), the [Navigation](#)<sup>p952</sup> object needs to keep track of the following:

State	Duration	Explanation
The <a href="#">NavigateEvent</a> <sup>p970</sup>	For the duration of event firing	So that if the navigation is canceled while the event is firing, we can <a href="#">cancel</a> the event
The event's <a href="#">abort controller</a> <sup>p972</sup>	Until all promises returned from handlers passed to <a href="#">intercept()</a> <sup>p972</sup> have settled	So that if the navigation is canceled, we can <a href="#">signal abort</a>
Whether a new element was <a href="#">focused</a> <sup>p842</sup>	Until all promises returned from handlers passed to <a href="#">intercept()</a> <sup>p972</sup> have settled	So that if one was, focus is not <a href="#">reset</a> <sup>p979</sup>
The <a href="#">NavigationHistoryEntry</a> <sup>p956</sup> being navigated to	From when it is determined, until all promises returned from handlers passed to <a href="#">intercept()</a> <sup>p972</sup> have settled	So that we know what to resolve any <a href="#">committed</a> <sup>p952</sup> and <a href="#">finished</a> <sup>p952</sup> promises with
Any <a href="#">finished</a> <sup>p952</sup> promise that	Until all promises returned from handlers passed to <a href="#">intercept()</a> <sup>p972</sup>	So that we can resolve or reject it appropriately

State	Duration	Explanation
was returned	have settled	

For non-"[traverse](#)<sup>p954</sup>" navigations

State	Duration	Explanation
Any <a href="#">state</a> <sup>p952</sup>	For the duration of event firing	So that we can update the current entry's <a href="#">navigation API state</a> <sup>p1005</sup> if the event finishes firing without being <a href="#">canceled</a>

For "[traverse](#)<sup>p954</sup>" navigations

State	Duration	Explanation
Any <a href="#">info</a> <sup>p952</sup>	Until the task is queued to fire the <a href="#">navigate</a> <sup>p1472</sup> event	So that we can use it to fire the <a href="#">navigate</a> <sup>p1472</sup> after the trip through the <a href="#">session history traversal queue</a> <sup>p990</sup> .
Any <a href="#">committed</a> <sup>p952</sup> promise that was returned	Until the session history is updated (inside that same task)	So that we can resolve or reject it appropriately
Whether <a href="#">intercept()</a> <sup>p972</sup> was called	Until the session history is updated (inside that same task)	So that we can suppress the normal scroll restoration logic in favor of the behavior given by the <a href="#">scroll</a> <sup>p970</sup> option

We also cannot assume there is only a single navigation requested at any given time, due to web developer code such as:

```
const p1 = navigation.navigate(url1).finished;
const p2 = navigation.navigate(url2).finished;
```

That is, in this scenario, we need to ensure that while navigating to url2, we still have the promise p1 around so that we can reject it. We can't just get rid of any ongoing navigation promises the moment the second call to [navigate\(\)](#)<sup>p960</sup> happens.

We end up accomplishing all this by associating the following with each [Navigation](#)<sup>p952</sup>:

- **Ongoing [navigate](#) event**, a [NavigateEvent](#)<sup>p970</sup> or null, initially null.
- **Focus changed during ongoing navigation**, a boolean, initially false.
- **Suppress normal scroll restoration during ongoing navigation**, a boolean, initially false.
- **Ongoing API method tracker**, a [navigation API method tracker](#)<sup>p964</sup> or null, initially null.
- **Upcoming non-traverse API method tracker**, a [navigation API method tracker](#)<sup>p964</sup> or null, initially null.
- **Upcoming traverse API method trackers**, an [ordered map](#) from strings to [navigation API method trackers](#)<sup>p964</sup>, initially empty.

#### Note

*The state here that is not stored in [navigation API method trackers](#)<sup>p964</sup> is state which needs to be tracked even for navigations that are not initiated via navigation API methods.*

A **navigation API method tracker** is a [struct](#) with the following [items](#):

- A **navigation object**, a [Navigation](#)<sup>p952</sup>
- A **key**, a string or null
- An **info**, a JavaScript value
- A **serialized state**, a [serialized state](#)<sup>p1006</sup> or null
- A **committed-to entry**, a [NavigationHistoryEntry](#)<sup>p956</sup> or null
- A **committed promise**, a promise
- A **finished promise**, a promise

All this state is then managed via the following algorithms.

To **maybe set the upcoming non-traverse API method tracker** given a [Navigation](#)<sup>p952</sup> *navigation*, a JavaScript value *info*, and a [serialized state](#)<sup>p1006</sup>-or-null *serializedState*:

1. Let *committedPromise* and *finishedPromise* be new promises created in *navigation*'s [relevant realm](#)<sup>p1083</sup>.

2. [Mark as handled](#) `finishedPromise`.

#### Note

*The web developer doesn't necessarily care about `finishedPromise` being rejected:*

- They might only care about `committedPromise`.
- They could be doing multiple synchronous navigations within the same task, in which case all but the last will be aborted (causing their `finishedPromise` to reject). This could be an application bug, but also could just be an emergent feature of disparate parts of the application overriding each others' actions.
- They might prefer to listen to other transition-failure signals instead of `finishedPromise`, e.g., the [navigateerror](#)<sup>p1472</sup> event, or the [navigation.transition.finished](#)<sup>p969</sup> promise.

*As such, we mark it as handled to ensure that it never triggers [unhandledrejection](#)<sup>p1472</sup> events.*

3. Let `apiMethodTracker` be a new [navigation API method tracker](#)<sup>p964</sup> with:

[navigation object](#)<sup>p964</sup>

`navigation`

[key](#)<sup>p964</sup>

`null`

[info](#)<sup>p964</sup>

`info`

[serialized state](#)<sup>p964</sup>

`serializedState`

[committed-to entry](#)<sup>p964</sup>

`null`

[committed promise](#)<sup>p964</sup>

`committedPromise`

[finished promise](#)<sup>p964</sup>

`finishedPromise`

4. [Assert](#): `navigation`'s [upcoming non-traverse API method tracker](#)<sup>p964</sup> is `null`.
5. If `navigation` does not [have entries and events disabled](#)<sup>p953</sup>, then set `navigation`'s [upcoming non-traverse API method tracker](#)<sup>p964</sup> to `apiMethodTracker`.

#### Note

*If `navigation` [has entries and events disabled](#)<sup>p953</sup>, then `committedPromise` and `finishedPromise` will never fulfill (since we never create a [NavigationHistoryEntry](#)<sup>p956</sup> object for such [Document](#)<sup>p130</sup>s, and so we have nothing to resolve them with); there is no [NavigationHistoryEntry](#)<sup>p956</sup> to apply `serializedState` to; and there is no [navigate](#)<sup>p1472</sup> event to include `info` with. So, we don't need to track this API method call after all.*

6. Return `apiMethodTracker`.

To **add an upcoming traverse API method tracker** given a [Navigation](#)<sup>p952</sup> `navigation`, a string `destinationKey`, and a JavaScript value `info`:

1. Let `committedPromise` and `finishedPromise` be new promises created in `navigation`'s [relevant realm](#)<sup>p1083</sup>.
2. [Mark as handled](#) `finishedPromise`.

#### Note

*See the [previous discussion](#)<sup>p965</sup> about why this is done.*

3. Let `apiMethodTracker` be a new [navigation API method tracker](#)<sup>p964</sup> with:

[navigation object](#)<sup>p964</sup>

`navigation`

[key](#)<sup>p964</sup>

`destinationKey`

[info](#)<sup>p964</sup>

`info`

[serialized state](#)<sup>p964</sup>

null

[committed-to entry](#)<sup>p964</sup>

null

[committed promise](#)<sup>p964</sup>

committedPromise

[finished promise](#)<sup>p964</sup>

finishedPromise

4. Set *navigation*'s [upcoming traverse API method trackers](#)<sup>p964</sup>[*key*] to *apiMethodTracker*.
5. Return *apiMethodTracker*.

To **promote an upcoming API method tracker to ongoing** given a [Navigation](#)<sup>p952</sup> *navigation* and a string-or-null *destinationKey*:

1. **Assert**: *navigation*'s [ongoing API method tracker](#)<sup>p964</sup> is null.
2. If *destinationKey* is not null, then:
  1. **Assert**: *navigation*'s [upcoming non-traverse API method tracker](#)<sup>p964</sup> is null.
  2. If *navigation*'s [upcoming traverse API method trackers](#)<sup>p964</sup>[*destinationKey*] **exists**, then:
    1. Set *navigation*'s [ongoing API method tracker](#)<sup>p964</sup> to *navigation*'s [upcoming traverse API method trackers](#)<sup>p964</sup>[*destinationKey*].
    2. **Remove** *navigation*'s [upcoming traverse API method trackers](#)<sup>p964</sup>[*destinationKey*].
3. Otherwise:
  1. Set *navigation*'s [ongoing API method tracker](#)<sup>p964</sup> to *navigation*'s [upcoming non-traverse API method tracker](#)<sup>p964</sup>.
  2. Set *navigation*'s [upcoming non-traverse API method tracker](#)<sup>p964</sup> to null.

To **clean up** a [navigation API method tracker](#)<sup>p964</sup> *apiMethodTracker*:

1. Let *navigation* be *apiMethodTracker*'s [navigation object](#)<sup>p964</sup>.
2. If *navigation*'s [ongoing API method tracker](#)<sup>p964</sup> is *apiMethodTracker*, then set *navigation*'s [ongoing API method tracker](#)<sup>p964</sup> to null.
3. Otherwise:
  1. Let *key* be *apiMethodTracker*'s [key](#)<sup>p964</sup>.
  2. **Assert**: *key* is not null.
  3. **Assert**: *navigation*'s [upcoming traverse API method trackers](#)<sup>p964</sup>[*key*] **exists**.
  4. **Remove** *navigation*'s [upcoming traverse API method trackers](#)<sup>p964</sup>[*key*].

To **notify about the committed-to entry** given a [navigation API method tracker](#)<sup>p964</sup> *apiMethodTracker* and a [NavigationHistoryEntry](#)<sup>p956</sup> *nhe*:

1. Set *apiMethodTracker*'s [committed-to entry](#)<sup>p964</sup> to *nhe*.
2. If *apiMethodTracker*'s [serialized state](#)<sup>p964</sup> is not null, then set *nhe*'s [session history entry](#)<sup>p957</sup>'s [navigation API state](#)<sup>p1005</sup> to *apiMethodTracker*'s [serialized state](#)<sup>p964</sup>.

#### Note

If it's null, then we're traversing to *nhe* via [navigation.traverseTo\(\)](#)<sup>p962</sup>, which does not allow changing the state.

#### Note

At this point, *apiMethodTracker*'s [serialized state](#)<sup>p964</sup> is no longer needed. Implementations might want to clear it out to avoid keeping it alive for the lifetime of the [navigation API method tracker](#)<sup>p964</sup>.

3. Resolve *apiMethodTracker*'s [committed promise](#)<sup>p964</sup> with *nhe*.

#### Note

At this point, `apiMethodTracker`'s `committed promise`<sup>p964</sup> is only needed in cases where it has not yet been returned to author code. Implementations might want to clear it out to avoid keeping it alive for the lifetime of the `navigation API method tracker`<sup>p964</sup>.

To **resolve the finished promise** for a `navigation API method tracker`<sup>p964</sup> `apiMethodTracker`:

1. Resolve `apiMethodTracker`'s `committed promise`<sup>p964</sup> with its `committed-to entry`<sup>p964</sup>.

#### Note

Usually, `notify about the committed-to entry`<sup>p966</sup> has previously been called on `apiMethodTracker`, and so this will do nothing. However, in some cases `resolve the finished promise`<sup>p967</sup> is called directly, in which case this step is necessary.

2. Resolve `apiMethodTracker`'s `finished promise`<sup>p964</sup> with its `committed-to entry`<sup>p964</sup>.
3. `Clean up`<sup>p966</sup> `apiMethodTracker`.

To **reject the finished promise** for a `navigation API method tracker`<sup>p964</sup> `apiMethodTracker` with a JavaScript value exception:

1. Reject `apiMethodTracker`'s `committed promise`<sup>p964</sup> with exception.

#### Note

This will do nothing if `apiMethodTracker`'s `committed promise`<sup>p964</sup> was previously resolved via `notify about the committed-to entry`<sup>p966</sup>.

2. Reject `apiMethodTracker`'s `finished promise`<sup>p964</sup> with exception.
3. `Clean up`<sup>p966</sup> `apiMethodTracker`.

To **abort the ongoing navigation** given a `Navigation`<sup>p952</sup> `navigation` and an optional `DOMException` error:

1. Let event be `navigation`'s `ongoing navigate event`<sup>p964</sup>.
2. `Assert`: event is not null.
3. Set `navigation`'s `focus changed during ongoing navigation`<sup>p964</sup> to false.
4. Set `navigation`'s `suppress normal scroll restoration during ongoing navigation`<sup>p964</sup> to false.
5. If error was not given, then let error be a new "AbortError" `DOMException` created in `navigation`'s `relevant realm`<sup>p1083</sup>.
6. If event's `dispatch flag` is set, then set event's `canceled flag` to true.
7. `Signal abort` on event's `abort controller`<sup>p972</sup> given error.
8. Set `navigation`'s `ongoing navigate event`<sup>p964</sup> to null.
9. Let `errorInfo` be the result of `extracting error information`<sup>p1098</sup> from error.

#### Note

For example, if this algorithm is reached because of a call to `window.stop()`<sup>p928</sup>, these properties would probably end up initialized based on the line of script that called `window.stop()`<sup>p928</sup>. But if it's because the user clicked the stop button, these properties would probably end up with default values like the empty string or 0.

10. `Fire an event` named `navigateerror`<sup>p1472</sup> at `navigation` using `ErrorEvent`<sup>p1099</sup>, with additional attributes initialized according to `errorInfo`.
11. If `navigation`'s `ongoing API method tracker`<sup>p964</sup> is non-null, then `reject the finished promise`<sup>p967</sup> for `apiMethodTracker` with error.
12. If `navigation`'s `transition`<sup>p968</sup> is not null, then:
  1. Reject `navigation`'s `transition`<sup>p968</sup>'s `finished promise`<sup>p968</sup> with error.
  2. Set `navigation`'s `transition`<sup>p968</sup> to null.

To **inform the navigation API about aborting navigation** in a `navigable`<sup>p989</sup> `navigable`:

1. If this algorithm is running on *navigable*'s [active window](#)<sup>p989</sup>'s [relevant agent](#)<sup>p1073</sup>'s [event loop](#)<sup>p1123</sup>, then continue on to the following steps. Otherwise, [queue a global task](#)<sup>p1125</sup> on the [navigation and traversal task source](#)<sup>p1134</sup> given *navigable*'s [active window](#)<sup>p989</sup> to run the following steps.
2. Let *navigation* be *navigable*'s [active window](#)<sup>p989</sup>'s [navigation API](#)<sup>p952</sup>.
3. If *navigation*'s [ongoing navigate event](#)<sup>p964</sup> is null, then return.
4. [Abort the ongoing navigation](#)<sup>p967</sup> given *navigation*.

To **inform the navigation API about child navigable destruction** given a [navigable](#)<sup>p989</sup> *navigable*:

1. [Inform the navigation API about aborting navigation](#)<sup>p967</sup> in *navigable*.
2. Let *navigation* be *navigable*'s [active window](#)<sup>p989</sup>'s [navigation API](#)<sup>p952</sup>.
3. Let *traversalAPIMethodTrackers* be a [clone](#) of *navigation*'s [upcoming traverse API method trackers](#)<sup>p964</sup>.
4. [For each](#) *apiMethodTracker* of *traversalAPIMethodTrackers*: [reject the finished promise](#)<sup>p967</sup> for *apiMethodTracker* with a new ["AbortError" DOMException](#) created in *navigation*'s [relevant realm](#)<sup>p1083</sup>.

The ongoing navigation concept is most-directly exposed to web developers through the [navigation.transition](#)<sup>p968</sup> property, which is an instance of the [NavigationTransition](#)<sup>p968</sup> interface:

```
IDL [Exposed=Window]
interface NavigationTransition {
  readonly attribute NavigationType navigationType;
  readonly attribute NavigationHistoryEntry from;
  readonly attribute Promise<undefined> finished;
};
```

#### For web developers (non-normative)

##### [navigation](#)<sup>p952</sup>.[transition](#)<sup>p968</sup>

A [NavigationTransition](#)<sup>p968</sup> representing any ongoing navigation that hasn't yet reached the [navigatesuccess](#)<sup>p1472</sup> or [navigateerror](#)<sup>p1472</sup> stage, if one exists; or null, if there is no such transition ongoing.

Since [navigation.currentEntry](#)<sup>p958</sup> (and other properties like [location.href](#)<sup>p939</sup>) are updated immediately upon navigation, this [navigation.transition](#)<sup>p968</sup> property is useful for determining when such navigations are not yet fully settled, according to any handlers passed to [navigateEvent.intercept\(\)](#)<sup>p972</sup>.

##### [navigation](#)<sup>p952</sup>.[transition](#)<sup>p968</sup>.[navigationType](#)<sup>p968</sup>

One of ["push"](#)<sup>p953</sup>, ["replace"](#)<sup>p953</sup>, ["reload"](#)<sup>p954</sup>, or ["traverse"](#)<sup>p954</sup>, indicating what type of navigation this transition is for.

##### [navigation](#)<sup>p952</sup>.[transition](#)<sup>p968</sup>.[from](#)<sup>p968</sup>

The [NavigationHistoryEntry](#)<sup>p956</sup> from which the transition is coming. This can be useful to compare against [navigation.currentEntry](#)<sup>p958</sup>.

##### [navigation](#)<sup>p952</sup>.[transition](#)<sup>p968</sup>.[finished](#)<sup>p969</sup>

A promise which fulfills at the same time as the [navigatesuccess](#)<sup>p1472</sup> fires, or rejects at the same time the [navigateerror](#)<sup>p1472</sup> event fires.

Each [Navigation](#)<sup>p952</sup> has a **transition**, which is a [NavigationTransition](#)<sup>p968</sup> or null, initially null.

The **transition** getter steps are to return *this*'s [transition](#)<sup>p968</sup>.

Each [NavigationTransition](#)<sup>p968</sup> has an associated **navigation type**, which is a [NavigationType](#)<sup>p953</sup>.

Each [NavigationTransition](#)<sup>p968</sup> has an associated **from entry**, which is a [NavigationHistoryEntry](#)<sup>p956</sup>.

Each [NavigationTransition](#)<sup>p968</sup> has an associated **finished promise**, which is a promise.

The **navigationType** getter steps are to return *this*'s [navigation type](#)<sup>p968</sup>.

The **from** getter steps are to return *this*'s [from entry](#)<sup>p968</sup>.

The **finished** getter steps are to return [this's finished promise](#)<sup>p968</sup>.

#### 7.2.6.9 The [NavigationActivation](#)<sup>p969</sup> interface §<sup>p96</sup><sub>9</sub>

IDL [Exposed=Window]

```
interface NavigationActivation {  
  readonly attribute NavigationHistoryEntry? from;  
  readonly attribute NavigationHistoryEntry entry;  
  readonly attribute NavigationType navigationType;  
};
```

For web developers (non-normative)

##### [navigation](#)<sup>p952</sup>.[activation](#)<sup>p969</sup>

A [NavigationActivation](#)<sup>p969</sup> containing information about the most recent cross-document navigation, the navigation that "activated" this [Document](#)<sup>p130</sup>.

While [navigation.currentEntry](#)<sup>p958</sup> and the [Document](#)<sup>p130</sup>'s URL can be updated regularly due to same-document navigations, [navigation.activation](#)<sup>p969</sup> stays constant, and its properties are only updated if the [Document](#)<sup>p130</sup> is [reactivated](#)<sup>p1051</sup> from history.

##### [navigation](#)<sup>p952</sup>.[activation](#)<sup>p969</sup>.[entry](#)<sup>p969</sup>

A [NavigationHistoryEntry](#)<sup>p956</sup>, equivalent to the value of the [navigation.currentEntry](#)<sup>p958</sup> property at the moment the [Document](#)<sup>p130</sup> was activated.

##### [navigation](#)<sup>p952</sup>.[activation](#)<sup>p969</sup>.[from](#)<sup>p969</sup>

A [NavigationHistoryEntry](#)<sup>p956</sup>, representing the [Document](#)<sup>p130</sup> that was active right before the current [Document](#)<sup>p130</sup>. This will have a value null in case the previous [Document](#)<sup>p130</sup> was not [same origin](#)<sup>p899</sup> with this one or if it was the [initial about:blank](#)<sup>p131</sup> [Document](#)<sup>p130</sup>.

There are some cases in which either the [from](#)<sup>p969</sup> or [entry](#)<sup>p969</sup> [NavigationHistoryEntry](#)<sup>p956</sup> objects would not be viable targets for the [traverseTo\(\)](#)<sup>p962</sup> method, as they might not be retained in history. For example, the [Document](#)<sup>p130</sup> can be activated using [location.replace\(\)](#)<sup>p942</sup> or its initial entry could be replaced by [history.replaceState\(\)](#)<sup>p946</sup>. However, those entries' [url](#)<sup>p957</sup> property and [getState\(\)](#)<sup>p958</sup> method are still accessible.

##### [navigation](#)<sup>p952</sup>.[activation](#)<sup>p969</sup>.[navigationType](#)<sup>p969</sup>

One of "[push](#)<sup>p953</sup>", "[replace](#)<sup>p953</sup>", "[reload](#)<sup>p954</sup>", or "[traverse](#)<sup>p954</sup>", indicating what type of navigation activated this [Document](#)<sup>p130</sup>.

Each [Navigation](#)<sup>p952</sup> has an associated **activation**, which is null or a [NavigationActivation](#)<sup>p969</sup> object, initially null.

Each [NavigationActivation](#)<sup>p969</sup> has:

- **old entry**, null or a [NavigationHistoryEntry](#)<sup>p956</sup>.
- **new entry**, null or a [NavigationHistoryEntry](#)<sup>p956</sup>.
- **navigation type**, a [NavigationType](#)<sup>p953</sup>.

The **activation** getter steps are to return [this's activation](#)<sup>p969</sup>.

The **from** getter steps are to return [this's old entry](#)<sup>p969</sup>.

The **entry** getter steps are to return [this's new entry](#)<sup>p969</sup>.

The **navigationType** getter steps are to return [this's navigation type](#)<sup>p969</sup>.

#### 7.2.6.10 The [navigate](#)<sup>p1472</sup> event §<sup>p96</sup><sub>9</sub>

A major feature of the navigation API is the [navigate](#)<sup>p1472</sup> event. This event is fired on any navigation (in the [broad sense of the word](#)<sup>p953</sup>), allowing web developers to monitor such outgoing navigations. In many cases, the event is [cancelable](#), which allows preventing the navigation from happening. And in others, the navigation can be intercepted and replaced with a same-document navigation by using the [intercept\(\)](#)<sup>p972</sup> method of the [NavigateEvent](#)<sup>p970</sup> class.

### 7.2.6.10.1 The `NavigateEvent`<sup>p970</sup> interface §<sup>p97</sup><sub>0</sub>

IDL

```
[Exposed=Window]
interface NavigateEvent : Event {
    constructor(DOMString type, NavigateEventInit eventInitDict);

    readonly attribute NavigationType navigationType;
    readonly attribute NavigationDestination destination;
    readonly attribute boolean canIntercept;
    readonly attribute boolean userInitiated;
    readonly attribute boolean hashChange;
    readonly attribute AbortSignal signal;
    readonly attribute FormData? formData;
    readonly attribute DOMString? downloadRequest;
    readonly attribute any info;
    readonly attribute boolean hasUAVisualTransition;

    undefined intercept(optional NavigationInterceptOptions options = {});
    undefined scroll();
};

dictionary NavigateEventInit : EventInit {
    NavigationType navigationType = "push";
    required NavigationDestination destination;
    boolean canIntercept = false;
    boolean userInitiated = false;
    boolean hashChange = false;
    required AbortSignal signal;
    FormData? formData = null;
    DOMString? downloadRequest = null;
    any info;
    boolean hasUAVisualTransition = false;
};

dictionary NavigationInterceptOptions {
    NavigationInterceptHandler handler;
    NavigationFocusReset focusReset;
    NavigationScrollBehavior scroll;
};

enum NavigationFocusReset {
    "after-transition",
    "manual"
};

enum NavigationScrollBehavior {
    "after-transition",
    "manual"
};

callback NavigationInterceptHandler = Promise<undefined> ();
```

For web developers (non-normative)

#### `event.navigationType`<sup>p972</sup>

One of "`push`<sup>p953</sup>", "`replace`<sup>p953</sup>", "`reload`<sup>p954</sup>", or "`traverse`<sup>p954</sup>", indicating what type of navigation this is.

#### `event.destination`<sup>p972</sup>

A `NavigationDestination`<sup>p973</sup> representing the destination of the navigation.

#### `event.canIntercept`<sup>p972</sup>

True if `intercept()`<sup>p972</sup> can be called to intercept this navigation and convert it into a same-document navigation, replacing its

usual behavior; false otherwise.

Generally speaking, this will be true whenever the current [Document](#)<sup>p139</sup> can have its URL rewritten<sup>p947</sup> to the destination URL, except for in the case of cross-document "[traverse](#)"<sup>p954</sup> navigations, where it will always be false.

#### **`event.userInitiated`**<sup>p972</sup>

True if this navigation was due to a user clicking on an [a](#)<sup>p257</sup> element, submitting a [form](#)<sup>p514</sup> element, or using the [browser UI](#)<sup>p1069</sup> to navigate; false otherwise.

#### **`event.hashChange`**<sup>p972</sup>

True for a [fragment navigation](#)<sup>p1021</sup>; false otherwise.

#### **`event.signal`**<sup>p972</sup>

An [AbortSignal](#) which will become aborted if the navigation gets canceled, e.g., by the user pressing their browser's "Stop" button, or by another navigation interrupting this one.

The expected pattern is for developers to pass this along to any async operations, such as [fetch\(\)](#), which they perform as part of handling this navigation.

#### **`event.formData`**<sup>p972</sup>

The [FormData](#) representing the submitted form entries for this navigation, if this navigation is a "[push](#)"<sup>p953</sup> or "[replace](#)"<sup>p953</sup> navigation representing a POST [form submission](#)<sup>p629</sup>; null otherwise.

(Notably, this will be null even for "[reload](#)"<sup>p954</sup> or "[traverse](#)"<sup>p954</sup> navigations that are revisiting a [session history entry](#)<sup>p1005</sup> that was originally created from a form submission.)

#### **`event.downloadRequest`**<sup>p972</sup>

Represents whether or not this navigation was requested to be a download, by using an [a](#)<sup>p257</sup> or [area](#)<sup>p471</sup> element's [download](#)<sup>p383</sup> attribute:

- If a download was not requested, then this property is null.
- If a download was requested, returns the filename that was supplied as the [download](#)<sup>p383</sup> attribute's value. (This could be the empty string.)

Note that a download being requested does not always mean that a download will happen: for example, a download might be blocked by browser security policies, or end up being treated as a "[push](#)"<sup>p1014</sup> navigation for unspecified reasons.

Similarly, a navigation might end up being a download even if it was not requested to be one, due to the destination server responding with a ``Content-Disposition: attachment`` header.

Finally, note that the [navigate](#)<sup>p1472</sup> event will not fire at all for downloads initiated using browser UI affordances, e.g., those created by right-clicking and choosing to save the target of a link.

#### **`event.info`**<sup>p972</sup>

An arbitrary JavaScript value passed via one of the [navigation API methods](#)<sup>p959</sup> which initiated this navigation, or undefined if the navigation was initiated by the user or by a different API.

#### **`event.hasUAVisualTransition`**<sup>p972</sup>

Returns true if the user agent performed a visual transition for this navigation before dispatching this event. If true, the best user experience will be given if the author synchronously updates the DOM to the post-navigation state.

#### **`event.intercept`**<sup>p972</sup> ({ [handler](#)<sup>p970</sup>, [focusReset](#)<sup>p970</sup>, [scroll](#)<sup>p970</sup> })

Intercepts this navigation, preventing its normal handling and instead converting it into a same-document navigation of the same type to the destination URL.

The [handler](#)<sup>p970</sup> option can be a function that returns a promise. The handler function will run after the [navigate](#)<sup>p1472</sup> event has finished firing, and the [navigation.currentEntry](#)<sup>p958</sup> property has been synchronously updated. This returned promise is used to signal the duration, and success or failure, of the navigation. After it settles, the browser signals to the user (e.g., via a loading spinner UI, or assistive technology) that the navigation is finished. Additionally, it fires [navigatesuccess](#)<sup>p1472</sup> or [navigateerror](#)<sup>p1472</sup> events as appropriate, which other parts of the web application can respond to.

By default, using this method will cause focus to reset when any handlers' returned promises settle. Focus will be reset to the first element with the [autofocus](#)<sup>p848</sup> attribute set, or [the body element](#)<sup>p136</sup> if the attribute isn't present. The [focusReset](#)<sup>p970</sup> option can be set to "[manual](#)"<sup>p970</sup> to avoid this behavior.

By default, using this method will delay the browser's scroll restoration logic for "[traverse](#)"<sup>p954</sup> or "[reload](#)"<sup>p954</sup> navigations, or its scroll-reset/scroll-to-a-fragment logic for "[push](#)"<sup>p953</sup> or "[replace](#)"<sup>p953</sup> navigations, until any handlers' returned promises settle. The [scroll](#)<sup>p970</sup> option can be set to "[manual](#)"<sup>p970</sup> to turn off any browser-driven scroll behavior entirely for this navigation, or

[scroll\(\)](#)<sup>p972</sup> can be called before the promise settles to trigger this behavior early.

This method will throw a ["SecurityError" DOMException](#) if [canIntercept](#)<sup>p972</sup> is false, or if [isTrusted](#) is false. It will throw an ["InvalidStateError" DOMException](#) if not called synchronously, during event dispatch.

#### **event.scroll**<sup>p972</sup> ()

For ["traverse"](#)<sup>p954</sup> or ["reload"](#)<sup>p954</sup> navigations, restores the scroll position using the browser's usual scroll restoration logic.

For ["push"](#)<sup>p953</sup> or ["replace"](#)<sup>p953</sup> navigations, either resets the scroll position to the top of the document or scrolls to the [fragment](#) specified by [destination.url](#)<sup>p974</sup> if there is one.

If called more than once, or called after automatic post-transition scroll processing has happened due to the [scroll](#)<sup>p970</sup> option being left as ["after-transition"](#)<sup>p970</sup>, or called before the navigation has committed, this method will throw an ["InvalidStateError" DOMException](#).

Each [NavigateEvent](#)<sup>p970</sup> has an **interception state**, which is either "none", "intercepted", "committed", "scrolled", or "finished", initially "none".

Each [NavigateEvent](#)<sup>p970</sup> has a **navigation handler list**, a [list](#) of [NavigationInterceptHandler](#)<sup>p970</sup> callbacks, initially empty.

Each [NavigateEvent](#)<sup>p970</sup> has a **focus reset behavior**, a [NavigationFocusReset](#)<sup>p970</sup>-or-null, initially null.

Each [NavigateEvent](#)<sup>p970</sup> has a **scroll behavior**, a [NavigationScrollBehavior](#)<sup>p970</sup>-or-null, initially null.

Each [NavigateEvent](#)<sup>p970</sup> has an **abort controller**, an [AbortController](#)-or-null, initially null.

Each [NavigateEvent](#)<sup>p970</sup> has a **classic history API state**, a [serialized state](#)<sup>p1006</sup> or null. It is only used in some cases where the event's [navigationType](#)<sup>p972</sup> is ["push"](#)<sup>p953</sup> or ["replace"](#)<sup>p953</sup>, and is set appropriately when the event is [fired](#).

The [navigationType](#), [destination](#), [canIntercept](#), [userInitiated](#), [hashChange](#), [signal](#), [formData](#), [downloadRequest](#), [info](#), and [hasUAVisualTransition](#) attributes must return the values they are initialized to.

The [intercept\(options\)](#) method steps are:

1. [Perform shared checks](#)<sup>p973</sup> given [this](#).
2. If [this](#)'s [canIntercept](#)<sup>p972</sup> attribute was initialized to false, then throw a ["SecurityError" DOMException](#).
3. If [this](#)'s [dispatch flag](#) is unset, then throw an ["InvalidStateError" DOMException](#).
4. [Assert](#): [this](#)'s [interception state](#)<sup>p972</sup> is either "none" or "intercepted".
5. Set [this](#)'s [interception state](#)<sup>p972</sup> to "intercepted".
6. If [options](#)["[handler](#)<sup>p970</sup>"] [exists](#), then [append](#) it to [this](#)'s [navigation handler list](#)<sup>p972</sup>.
7. If [options](#)["[focusReset](#)<sup>p970</sup>"] [exists](#), then:
  1. If [this](#)'s [focus reset behavior](#)<sup>p972</sup> is not null, and it is not equal to [options](#)["[focusReset](#)<sup>p970</sup>"], then the user agent may [report a warning to the console](#) indicating that the [focusReset](#)<sup>p970</sup> option for a previous call to [intercept\(\)](#)<sup>p972</sup> was overridden by this new value, and the previous value will be ignored.
  2. Set [this](#)'s [focus reset behavior](#)<sup>p972</sup> to [options](#)["[focusReset](#)<sup>p970</sup>"].
8. If [options](#)["[scroll](#)<sup>p970</sup>"] [exists](#), then:
  1. If [this](#)'s [scroll behavior](#)<sup>p972</sup> is not null, and it is not equal to [options](#)["[scroll](#)<sup>p970</sup>"], then the user agent may [report a warning to the console](#) indicating that the [scroll](#)<sup>p970</sup> option for a previous call to [intercept\(\)](#)<sup>p972</sup> was overridden by this new value, and the previous value will be ignored.
  2. Set [this](#)'s [scroll behavior](#)<sup>p972</sup> to [options](#)["[scroll](#)<sup>p970</sup>"].

The [scroll\(\)](#) method steps are:

1. [Perform shared checks](#)<sup>p973</sup> given [this](#).
2. If [this](#)'s [interception state](#)<sup>p972</sup> is not "committed", then throw an ["InvalidStateError" DOMException](#).

3. [Process scroll behavior](#)<sup>p980</sup> given [this](#).

To perform shared checks for a [NavigateEvent](#)<sup>p970</sup> event:

1. If event's [relevant global object](#)<sup>p1083</sup>'s [associated Document](#)<sup>p923</sup> is not [fully active](#)<sup>p1003</sup>, then throw an ["InvalidStateError"](#) [DOMException](#).
2. If event's [isTrusted](#) attribute was initialized to false, then throw a ["SecurityError"](#) [DOMException](#).
3. If event's [canceled flag](#) is set, then throw an ["InvalidStateError"](#) [DOMException](#).

#### 7.2.6.10.2 The [NavigationDestination](#)<sup>p973</sup> interface §<sup>p97</sup> 3

```
IDL [Exposed=Window]
interface NavigationDestination {
  readonly attribute USVString url;
  readonly attribute DOMString key;
  readonly attribute DOMString id;
  readonly attribute long long index;
  readonly attribute boolean sameDocument;

  any getState();
};
```

For web developers (non-normative)

[event.destination](#)<sup>p972</sup>.[url](#)<sup>p974</sup>

The URL being navigated to.

[event.destination](#)<sup>p972</sup>.[key](#)<sup>p974</sup>

The value of the [key](#)<sup>p957</sup> property of the destination [NavigationHistoryEntry](#)<sup>p956</sup>, if this is a ["traverse"](#)<sup>p954</sup> navigation, or the empty string otherwise.

[event.destination](#)<sup>p972</sup>.[id](#)<sup>p974</sup>

The value of the [id](#)<sup>p957</sup> property of the destination [NavigationHistoryEntry](#)<sup>p956</sup>, if this is a ["traverse"](#)<sup>p954</sup> navigation, or the empty string otherwise.

[event.destination](#)<sup>p972</sup>.[index](#)<sup>p974</sup>

The value of the [index](#)<sup>p957</sup> property of the destination [NavigationHistoryEntry](#)<sup>p956</sup>, if this is a ["traverse"](#)<sup>p954</sup> navigation, or  $-1$  otherwise.

[event.destination](#)<sup>p972</sup>.[sameDocument](#)<sup>p974</sup>

Indicates whether or not this navigation is to the same [Document](#)<sup>p130</sup> as the current one, or not. This will be true, for example, in the case of fragment navigations or [history.pushState\(\)](#)<sup>p946</sup> navigations.

Note that this property indicates the original nature of the navigation. If a cross-document navigation is converted into a same-document navigation using [navigateEvent.intercept\(\)](#)<sup>p972</sup>, that will not change the value of this property.

[event.destination](#)<sup>p972</sup>.[getState](#)<sup>p974</sup>()

For ["traverse"](#)<sup>p954</sup> navigations, returns the [deserialization](#)<sup>p122</sup> of the state stored in the destination [session history entry](#)<sup>p1005</sup>.

For ["push"](#)<sup>p953</sup> or ["replace"](#)<sup>p953</sup> navigations, returns the [deserialization](#)<sup>p122</sup> of the state passed to [navigation.navigate\(\)](#)<sup>p960</sup>, if the navigation was initiated by that method, or undefined if it wasn't.

For ["reload"](#)<sup>p954</sup> navigations, returns the [deserialization](#)<sup>p122</sup> of the state passed to [navigation.reload\(\)](#)<sup>p961</sup>, if the reload was initiated by that method, or undefined if it wasn't.

Each [NavigationDestination](#)<sup>p973</sup> has a **URL**, which is a [URL](#).

Each [NavigationDestination](#)<sup>p973</sup> has an **entry**, which is a [NavigationHistoryEntry](#)<sup>p956</sup> or null.

#### Note

It will be non-null if and only if the [NavigationDestination](#)<sup>p973</sup> corresponds to a ["traverse"](#)<sup>p954</sup> navigation.

Each [NavigationDestination](#)<sup>p973</sup> has a **state**, which is a [serialized state](#)<sup>p1006</sup>.

Each [NavigationDestination](#)<sup>p973</sup> has an **is same document**, which is a boolean.

The **url** getter steps are to return [this's URL](#)<sup>p973</sup>, [serialized](#).

The **key** getter steps are:

1. If [this's entry](#)<sup>p973</sup> is null, then return the empty string.
2. Return [this's entry](#)<sup>p973</sup>'s [key](#)<sup>p957</sup>.

The **id** getter steps are:

1. If [this's entry](#)<sup>p973</sup> is null, then return the empty string.
2. Return [this's entry](#)<sup>p973</sup>'s [ID](#)<sup>p957</sup>.

The **index** getter steps are:

1. If [this's entry](#)<sup>p973</sup> is null, then return  $-1$ .
2. Return [this's entry](#)<sup>p973</sup>'s [index](#)<sup>p957</sup>.

The **sameDocument** getter steps are to return [this's is same document](#)<sup>p974</sup>.

The **getState()** method steps are to return [StructuredDeserialize](#)<sup>p122</sup>([this's state](#)<sup>p974</sup>).

#### 7.2.6.10.3 Firing the event <sup>p97</sup><sub>4</sub>

Other parts of the standard fire the [navigate](#)<sup>p1472</sup> event, through a series of wrapper algorithms given in this section.

To **fire a traverse navigate event** at a [Navigation](#)<sup>p952</sup> *navigation* given a [session history entry](#)<sup>p1005</sup> *destinationSHE* and an optional [user navigation involvement](#)<sup>p1014</sup> *userInvolvement* (default "[none](#)<sup>p1014</sup>"):

1. Let *event* be the result of [creating an event](#) given [NavigateEvent](#)<sup>p970</sup>, in *navigation*'s [relevant realm](#)<sup>p1083</sup>.
2. Set *event*'s [classic history API state](#)<sup>p972</sup> to null.
3. Let *destination* be a new [NavigationDestination](#)<sup>p973</sup> created in *navigation*'s [relevant realm](#)<sup>p1083</sup>.
4. Set *destination*'s [URL](#)<sup>p973</sup> to *destinationSHE*'s [URL](#)<sup>p1005</sup>.
5. Let *destinationNHE* be the [NavigationHistoryEntry](#)<sup>p956</sup> in *navigation*'s [entry list](#)<sup>p953</sup> whose [session history entry](#)<sup>p957</sup> is *destinationSHE*, or null if no such [NavigationHistoryEntry](#)<sup>p956</sup> exists.
6. If *destinationNHE* is non-null, then:
  1. Set *destination*'s [entry](#)<sup>p973</sup> to *destinationNHE*.
  2. Set *destination*'s [state](#)<sup>p974</sup> to *destinationSHE*'s [navigation API state](#)<sup>p1005</sup>.
7. Otherwise,
  1. Set *destination*'s [entry](#)<sup>p973</sup> to null.
  2. Set *destination*'s [state](#)<sup>p974</sup> to [StructuredSerializeForStorage](#)<sup>p122</sup>(null).
8. Set *destination*'s [is same document](#)<sup>p974</sup> to true if *destinationSHE*'s [document](#)<sup>p1005</sup> is equal to *navigation*'s [relevant global object](#)<sup>p1083</sup>'s [associated Document](#)<sup>p923</sup>; otherwise false.
9. Return the result of performing the [inner navigate event firing algorithm](#)<sup>p975</sup> given *navigation*, "[traverse](#)<sup>p954</sup>", *event*, *destination*, *userInvolvement*, null, and null.

To **fire a push/replace/reload navigate event** at a [Navigation](#)<sup>p952</sup> *navigation* given a [NavigationType](#)<sup>p953</sup> *navigationType*, a [URL destinationURL](#), a boolean *isSameDocument*, an optional [user navigation involvement](#)<sup>p1014</sup> *userInvolvement* (default "[none](#)<sup>p1014</sup>"),

an optional [entry list](#)<sup>p632</sup>-or-null **formDataEntryList** (default null), an optional [serialized state](#)<sup>p1006</sup> **navigationAPIState** (default [StructuredSerializeForStorage](#)<sup>p122</sup> (null)), and an optional [serialized state](#)<sup>p1006</sup>-or-null **classicHistoryAPIState** (default null):

1. Let event be the result of [creating an event](#) given [NavigateEvent](#)<sup>p970</sup>, in navigation's [relevant realm](#)<sup>p1083</sup>.
2. Set event's [classic history API state](#)<sup>p972</sup> to **classicHistoryAPIState**.
3. Let destination be a new [NavigationDestination](#)<sup>p973</sup> created in navigation's [relevant realm](#)<sup>p1083</sup>.
4. Set destination's [URL](#)<sup>p973</sup> to destinationURL.
5. Set destination's [entry](#)<sup>p973</sup> to null.
6. Set destination's [state](#)<sup>p974</sup> to navigationAPIState.
7. Set destination's [is same document](#)<sup>p974</sup> to isSameDocument.
8. Return the result of performing the [inner navigate event firing algorithm](#)<sup>p975</sup> given navigation, navigationType, event, destination, userInvolvement, formDataEntryList, and null.

To fire a download request **navigate event** at a [Navigation](#)<sup>p952</sup> navigation given a URL **destinationURL**, a [user navigation involvement](#)<sup>p1014</sup> **userInvolvement**, and a string **filename**:

1. Let event be the result of [creating an event](#) given [NavigateEvent](#)<sup>p970</sup>, in navigation's [relevant realm](#)<sup>p1083</sup>.
2. Set event's [classic history API state](#)<sup>p972</sup> to null.
3. Let destination be a new [NavigationDestination](#)<sup>p973</sup> created in navigation's [relevant realm](#)<sup>p1083</sup>.
4. Set destination's [URL](#)<sup>p973</sup> to destinationURL.
5. Set destination's [entry](#)<sup>p973</sup> to null.
6. Set destination's [state](#)<sup>p974</sup> to [StructuredSerializeForStorage](#)<sup>p122</sup> (null).
7. Set destination's [is same document](#)<sup>p974</sup> to false.
8. Return the result of performing the [inner navigate event firing algorithm](#)<sup>p975</sup> given navigation, "push<sup>p953</sup>", event, destination, userInvolvement, null, and filename.

The **inner navigate event firing algorithm** consists of the following steps, given a [Navigation](#)<sup>p952</sup> navigation, a [NavigationType](#)<sup>p953</sup> navigationType, a [NavigateEvent](#)<sup>p970</sup> event, a [NavigationDestination](#)<sup>p973</sup> destination, a [user navigation involvement](#)<sup>p1014</sup> userInvolvement, an [entry list](#)<sup>p632</sup>-or-null formDataEntryList, and a string-or-null downloadRequestFilename:

1. If navigation [has entries and events disabled](#)<sup>p953</sup>, then:
  1. **Assert**: navigation's [ongoing API method tracker](#)<sup>p964</sup> is null.
  2. **Assert**: navigation's [upcoming non-traverse API method tracker](#)<sup>p964</sup> is null.
  3. **Assert**: navigation's [upcoming traverse API method trackers](#)<sup>p964</sup> is empty.
4. Return true.

#### Note

These assertions holds because [traverseTo\(\)](#)<sup>p962</sup>, [back\(\)](#)<sup>p962</sup>, and [forward\(\)](#)<sup>p962</sup> will immediately fail when entries and events are disabled (since there are no entries to traverse to), and if our starting point is instead [navigate\(\)](#)<sup>p960</sup> or [reload\(\)](#)<sup>p961</sup>, then we [avoided](#)<sup>p965</sup> setting the [upcoming non-traverse API method tracker](#)<sup>p964</sup> in the first place.

2. Let destinationKey be null.
3. If destination's [entry](#)<sup>p973</sup> is non-null, then set destinationKey to destination's [entry](#)<sup>p973</sup>'s [key](#)<sup>p957</sup>.
4. **Assert**: destinationKey is not the empty string.
5. [Promote an upcoming API method tracker to ongoing](#)<sup>p966</sup> given navigation and destinationKey.
6. Let apiMethodTracker be navigation's [ongoing API method tracker](#)<sup>p964</sup>.
7. Let navigable be navigation's [relevant global object](#)<sup>p1083</sup>'s [navigable](#)<sup>p923</sup>.

8. Let *document* be *navigation*'s [relevant global object](#)<sup>p1083</sup>'s [associated Document](#)<sup>p923</sup>.
9. If *document* [can have its URL rewritten](#)<sup>p947</sup> to *destination*'s [URL](#)<sup>p973</sup>, and either *destination*'s [is same document](#)<sup>p974</sup> is true or *navigationType* is not "[traverse](#)<sup>p954</sup>", then initialize event's [canIntercept](#)<sup>p972</sup> to true. Otherwise, initialize it to false.
10. Let *traverseCanBeCanceled* be true if all of the following are true:
  - *navigable* is a [top-level traversable](#)<sup>p990</sup>;
  - *destination*'s [is same document](#)<sup>p974</sup> is true; and
  - either *userInvolvement* is not "[browser UI](#)<sup>p1014</sup>", or *navigation*'s [relevant global object](#)<sup>p1083</sup> has [history-action activation](#)<sup>p830</sup>.

Otherwise, let it be false.

11. If either:
  - *navigationType* is not "[traverse](#)<sup>p954</sup>"; or
  - *traverseCanBeCanceled* is true,
 then initialize event's [cancelable](#) to true. Otherwise, initialize it to false.
12. Initialize event's [type](#) to "[navigate](#)<sup>p1472</sup>".
13. Initialize event's [navigationType](#)<sup>p972</sup> to *navigationType*.
14. Initialize event's [destination](#)<sup>p972</sup> to *destination*.
15. Initialize event's [downloadRequest](#)<sup>p972</sup> to *downloadRequestFilename*.
16. If *apiMethodTracker* is not null, then initialize event's [info](#)<sup>p972</sup> to *apiMethodTracker*'s [info](#)<sup>p964</sup>. Otherwise, initialize it to undefined.

#### Note

*At this point *apiMethodTracker*'s [info](#)<sup>p964</sup> is no longer needed and can be nulled out instead of keeping it alive for the lifetime of the [navigation API method tracker](#)<sup>p964</sup>.*

17. Initialize event's [hasUAVisualTransition](#)<sup>p972</sup> to true if a visual transition, to display a cached rendered state of the document's [latest entry](#)<sup>p1008</sup>, was done by the user agent. Otherwise, initialize it to false.
18. Set event's [abort controller](#)<sup>p972</sup> to a new [AbortController](#) created in *navigation*'s [relevant realm](#)<sup>p1083</sup>.
19. Initialize event's [signal](#)<sup>p972</sup> to event's [abort controller](#)<sup>p972</sup>'s [signal](#).
20. Let *currentURL* be *document*'s [URL](#).
21. If all of the following are true:
  - event's [classic history API state](#)<sup>p972</sup> is null;
  - *destination*'s [is same document](#)<sup>p974</sup> is true;
  - *destination*'s [URL](#)<sup>p973</sup> [equals](#) *currentURL* with [exclude fragments](#) set to true; and
  - *destination*'s [URL](#)<sup>p973</sup>'s [fragment](#) is not [identical to](#) *currentURL*'s [fragment](#),

then initialize event's [hashChange](#)<sup>p972</sup> to true. Otherwise, initialize it to false.

#### Note

*The first condition here means that [hashChange](#)<sup>p972</sup> will be true for [fragment navigations](#)<sup>p1021</sup>, but false for cases like `history.pushState(undefined, "", "#fragment")`.*

22. If *userInvolvement* is not "[none](#)<sup>p1014</sup>", then initialize event's [userInitiated](#)<sup>p972</sup> to true. Otherwise, initialize it to false.
23. If *formDataEntryList* is not null, then initialize event's [formData](#)<sup>p972</sup> to a new [FormData](#) created in *navigation*'s [relevant realm](#)<sup>p1083</sup>, associated to *formDataEntryList*. Otherwise, initialize it to null.
24. **Assert:** *navigation*'s [ongoing navigate event](#)<sup>p964</sup> is null.

25. Set *navigation*'s [ongoing\\_navigate\\_event](#)<sup>p964</sup> to event.
26. Set *navigation*'s [focus\\_changed\\_during\\_ongoing\\_navigation](#)<sup>p964</sup> to false.
27. Set *navigation*'s [suppress\\_normal\\_scroll\\_restoration\\_during\\_ongoing\\_navigation](#)<sup>p964</sup> to false.
28. Let *dispatchResult* be the result of [dispatching](#) event at *navigation*.
29. If *dispatchResult* is false:
  1. If *navigationType* is "[traverse](#)"<sup>p954</sup>, then [consume\\_history-action\\_user\\_activation](#)<sup>p831</sup> given *navigation*'s [relevant\\_global\\_object](#)<sup>p1083</sup>.
  2. If event's [abort\\_controller](#)<sup>p972</sup>'s [signal](#) is not [aborted](#), then [abort\\_the\\_ongoing\\_navigation](#)<sup>p967</sup> given *navigation*.
  3. Return false.
30. Let *endResultsSameDocument* be true if event's [interception\\_state](#)<sup>p972</sup> is not "none" or event's [destination](#)<sup>p972</sup>'s [is\\_same\\_document](#)<sup>p974</sup> is true.
31. [Prepare\\_to\\_run\\_script](#)<sup>p1097</sup> given *navigation*'s [relevant\\_settings\\_object](#)<sup>p1083</sup>.

#### Note

This is done to avoid the [JavaScript execution context stack](#) becoming empty right after any [currententrychange](#)<sup>p1471</sup> event handlers run as a result of the [URL and history update steps](#)<sup>p1028</sup> that could soon happen. If the stack were to become empty at that time, then it would immediately [perform a microtask checkpoint](#)<sup>p1131</sup>, causing various promise fulfillment handlers to run interleaved with the event handlers and before any handlers passed to [navigateEvent.intercept\(\)](#)<sup>p972</sup>. This is undesirable since it means promise handler ordering vs. [currententrychange](#)<sup>p1471</sup> event handler ordering vs. [intercept\(\)](#)<sup>p972</sup> handler ordering would be dependent on whether the navigation is happening with an empty [JavaScript execution context stack](#) (e.g., because the navigation was user-initiated) or with a nonempty one (e.g., because the navigation was caused by a JavaScript API call).

By inserting an otherwise-unnecessary [JavaScript execution context](#) onto the stack in this step, we essentially suppress the [perform a microtask checkpoint](#)<sup>p1131</sup> algorithm until later, thus ensuring that the sequence is always: [currententrychange](#)<sup>p1471</sup> event handlers, then [intercept\(\)](#)<sup>p972</sup> handlers, then promise handlers.

32. If event's [interception\\_state](#)<sup>p972</sup> is not "none":
  1. Set event's [interception\\_state](#)<sup>p972</sup> to "committed".
  2. Let *fromNHE* be the [current entry](#)<sup>p953</sup> of *navigation*.
  3. [Assert](#): *fromNHE* is not null.
  4. Set *navigation*'s [transition](#)<sup>p968</sup> to a new [NavigationTransition](#)<sup>p968</sup> created in *navigation*'s [relevant realm](#)<sup>p1083</sup>, whose [navigation\\_type](#)<sup>p968</sup> is *navigationType*, whose [from entry](#)<sup>p968</sup> is *fromNHE*, and whose [finished promise](#)<sup>p968</sup> is a new promise created in *navigation*'s [relevant realm](#)<sup>p1083</sup>.
  5. [Mark as handled](#) *navigation*'s [transition](#)<sup>p968</sup>'s [finished promise](#)<sup>p968</sup>.

#### Note

See the [discussion about other finished promises](#)<sup>p965</sup> to understand why this is done.

6. If *navigationType* is "[traverse](#)"<sup>p954</sup>, then set *navigation*'s [suppress\\_normal\\_scroll\\_restoration\\_during\\_ongoing\\_navigation](#)<sup>p964</sup> to true.

#### Note

If event's [scroll behavior](#)<sup>p972</sup> was set to "[after-transition](#)"<sup>p970</sup>, then scroll restoration will happen as part of [finishing](#)<sup>p979</sup> the relevant [NavigateEvent](#)<sup>p970</sup>. Otherwise, there will be no scroll restoration. That is, no navigation which is intercepted by [intercept\(\)](#)<sup>p972</sup> goes through the normal scroll restoration process; scroll restoration for such navigations is either done manually, by the web developer, or is done after the transition.

7. If *navigationType* is "[push](#)"<sup>p953</sup> or "[replace](#)"<sup>p953</sup>, then run the [URL and history update steps](#)<sup>p1028</sup> given *document* and event's [destination](#)<sup>p972</sup>'s [URL](#)<sup>p974</sup>, with [serialisedData](#)<sup>p1028</sup> set to event's [classic history API state](#)<sup>p972</sup> and [historyHandling](#)<sup>p1028</sup> set to *navigationType*.

**Note**

If navigationType is "[reload](#)<sup>p954</sup>", then we are converting a [reload](#)<sup>p1027</sup> into a "same-document reload", for which the [URL and history update steps](#)<sup>p1028</sup> are not appropriate. Navigation API-related stuff still happens, such as updating the [active session history entry](#)<sup>p989</sup>'s [navigation API state](#)<sup>p1005</sup> if this was caused by a call to [navigation.reload\(\)](#)<sup>p961</sup>, and all the [ongoing navigation tracking](#)<sup>p963</sup>.

If navigationType is "[traverse](#)<sup>p954</sup>", then this event firing is happening as part of [the traversal process](#)<sup>p1040</sup>, and that process will take care of performing the appropriate session history entry updates.

33. If `endResultIsSameDocument` is true:

1. Let `promisesList` be an empty [list](#).
2. [For each](#) handler of event's [navigation handler list](#)<sup>p972</sup>:
  1. [Append](#) the result of [invoking](#) handler with an empty arguments list to `promisesList`.
3. If `promisesList`'s [size](#) is 0, then set `promisesList` to « [a promise resolved with](#) undefined ».

**Note**

There is a subtle timing difference between how [waiting for all](#) schedules its success and failure steps when given zero promises versus  $\geq 1$  promises. For most uses of [waiting for all](#), this does not matter. However, with this API, there are so many events and promise handlers which could fire around the same time that the difference is pretty easily observable: it can cause the event/promise handler sequence to vary. (Some of the events and promises involved include: [navigatesuccess](#)<sup>p1472</sup> / [navigateerror](#)<sup>p1472</sup>, [currententrychange](#)<sup>p1471</sup>, [dispose](#)<sup>p1471</sup>, `apiMethodTracker`'s promises, and the [navigation.transition.finished](#)<sup>p969</sup> promise.)

4. [Wait for all](#) of `promisesList`, with the following success steps:
  1. If event's [relevant global object](#)<sup>p1083</sup> is not [fully active](#)<sup>p1003</sup>, then abort these steps.
  2. If event's [abort controller](#)<sup>p972</sup>'s [signal](#) is [aborted](#), then abort these steps.
  3. [Assert](#): event equals navigation's [ongoing navigate event](#)<sup>p964</sup>.
  4. Set navigation's [ongoing navigate event](#)<sup>p964</sup> to null.
  5. [Finish](#)<sup>p979</sup> event given true.
  6. [Fire an event](#) named [navigatesuccess](#)<sup>p1472</sup> at navigation.
  7. If `apiMethodTracker` is non-null, then [resolve the finished promise](#)<sup>p967</sup> for `apiMethodTracker`.
  8. If navigation's [transition](#)<sup>p968</sup> is not null, then resolve navigation's [transition](#)<sup>p968</sup>'s [finished promise](#)<sup>p968</sup> with undefined.
  9. Set navigation's [transition](#)<sup>p968</sup> to null.

and the following failure steps given reason `rejectionReason`:

1. If event's [relevant global object](#)<sup>p1083</sup> is not [fully active](#)<sup>p1003</sup>, then abort these steps.
2. If event's [abort controller](#)<sup>p972</sup>'s [signal](#) is [aborted](#), then abort these steps.
3. [Assert](#): event equals navigation's [ongoing navigate event](#)<sup>p964</sup>.
4. Set navigation's [ongoing navigate event](#)<sup>p964</sup> to null.
5. [Finish](#)<sup>p979</sup> event given false.
6. Let `errorInfo` be the result of [extracting error information](#)<sup>p1098</sup> from `rejectionReason`.
7. [Fire an event](#) named [navigateerror](#)<sup>p1472</sup> at navigation using [ErrorEvent](#)<sup>p1099</sup>, with additional attributes initialized according to `errorInfo`.
8. If `apiMethodTracker` is non-null, then [reject the finished promise](#)<sup>p967</sup> for `apiMethodTracker` with `rejectionReason`.
9. If navigation's [transition](#)<sup>p968</sup> is not null, then reject navigation's [transition](#)<sup>p968</sup>'s [finished promise](#)<sup>p968</sup> with

*rejectionReason*.

10. Set *navigation*'s [transition](#)<sup>p968</sup> to null.
34. Otherwise, if *apiMethodTracker* is non-null, then [clean up](#)<sup>p966</sup> *apiMethodTracker*.
35. [Clean up after running script](#)<sup>p1097</sup> given *navigation*'s [relevant settings object](#)<sup>p1083</sup>.

**Note**

*Per the [previous note](#)<sup>p977</sup>, this stops suppressing any potential promise handler microtasks, causing them to run at this point or later.*

36. If event's [interception state](#)<sup>p972</sup> is "none", then return true.
37. Return false.

#### 7.2.6.10.4 Scroll and focus behavior <sup>p979</sup>

By calling [navigateEvent.intercept\(\)](#)<sup>p972</sup>, web developers can suppress the normal scroll and focus behavior for same-document navigations, instead invoking cross-document navigation-like behavior at a later time. The algorithms in this section are called at those appropriate later points.

To **finish** a [NavigateEvent](#)<sup>p970</sup> event, given a boolean *didFulfill*:

1. **Assert:** event's [interception state](#)<sup>p972</sup> is not "intercepted" or "finished".
2. If event's [interception state](#)<sup>p972</sup> is "none", then return.
3. [Potentially reset the focus](#)<sup>p979</sup> given event.
4. If *didFulfill* is true, then [potentially process scroll behavior](#)<sup>p979</sup> given event.
5. Set event's [interception state](#)<sup>p972</sup> to "finished".

To **potentially reset the focus** given a [NavigateEvent](#)<sup>p970</sup> event:

1. **Assert:** event's [interception state](#)<sup>p972</sup> is "committed" or "scrolled".
2. Let *navigation* be event's [relevant global object](#)<sup>p1083</sup>'s [navigation API](#)<sup>p952</sup>.
3. Let *focusChanged* be *navigation*'s [focus changed during ongoing navigation](#)<sup>p964</sup>.
4. Set *navigation*'s [focus changed during ongoing navigation](#)<sup>p964</sup> to false.
5. If *focusChanged* is true, then return.
6. If event's [focus reset behavior](#)<sup>p972</sup> is "[manual](#)<sup>p970</sup>", then return.

**Note**

*If it was left as null, then we treat that as "[after-transition](#)<sup>p970</sup>", and continue onward.*

7. Let *document* be event's [relevant global object](#)<sup>p1083</sup>'s [associated Document](#)<sup>p923</sup>.
8. Let *focusTarget* be the [autofocus delegate](#)<sup>p841</sup> for *document*.
9. If *focusTarget* is null, then set *focusTarget* to *document*'s [body element](#)<sup>p136</sup>.
10. If *focusTarget* is null, then set *focusTarget* to *document*'s [document element](#).
11. Run the [focusing steps](#)<sup>p842</sup> for *focusTarget*, with *document*'s [viewport](#) as the *fallback target*.
12. Move the [sequential focus navigation starting point](#)<sup>p844</sup> to *focusTarget*.

To **potentially process scroll behavior** given a [NavigateEvent](#)<sup>p970</sup> event:

1. **Assert:** event's [interception state](#)<sup>p972</sup> is "committed" or "scrolled".

2. If event's [interception state](#)<sup>p972</sup> is "scrolled", then return.
3. If event's [scroll behavior](#)<sup>p972</sup> is "[manual](#)<sup>p970</sup>", then return.

#### Note

If it was left as null, then we treat that as "[after-transition](#)<sup>p970</sup>", and continue onward.

4. [Process scroll behavior](#)<sup>p980</sup> given event.

To **process scroll behavior** given a [NavigateEvent](#)<sup>p970</sup> event:

1. **Assert:** event's [interception state](#)<sup>p972</sup> is "committed".
2. Set event's [interception state](#)<sup>p972</sup> to "scrolled".
3. If event's [navigationType](#)<sup>p972</sup> was initialized to "[traverse](#)<sup>p954</sup>" or "[reload](#)<sup>p954</sup>", then [restore scroll position data](#)<sup>p1055</sup> given event's [relevant global object](#)<sup>p1083</sup>'s [navigable](#)<sup>p923</sup>'s [active session history entry](#)<sup>p989</sup>.
4. Otherwise:
  1. Let *document* be event's [relevant global object](#)<sup>p1083</sup>'s [associated Document](#)<sup>p923</sup>.
  2. If *document*'s [indicated part](#)<sup>p1054</sup> is null, then [scroll to the beginning of the document](#) given *document*.  
[\[CSSOMVIEW\]](#)<sup>p1477</sup>
  3. Otherwise, [scroll to the fragment](#)<sup>p1054</sup> given *document*.

## 7.2.7 Event interfaces §<sup>p98</sup><sub>0</sub>

#### Note

The [NavigateEvent](#)<sup>p970</sup> interface has *its own dedicated section*<sup>p969</sup>, due to its complexity.

### 7.2.7.1 The [NavigationCurrentEntryChangeEvent](#)<sup>p980</sup> interface §<sup>p98</sup><sub>0</sub>

```
IDL
[Exposed=Window]
interface NavigationCurrentEntryChangeEvent : Event {
  constructor(DOMString type, NavigationCurrentEntryChangeEventInit eventInitDict);

  readonly attribute NavigationType? navigationType;
  readonly attribute NavigationHistoryEntry from;
};

dictionary NavigationCurrentEntryChangeEventInit : EventInit {
  NavigationType? navigationType = null;
  required NavigationHistoryEntry from;
};
```

#### For web developers (non-normative)

##### **event.navigationType**<sup>p980</sup>

Returns the type of navigation which caused the current entry to change, or null if the change is due to [navigation.updateCurrentEntry\(\)](#)<sup>p958</sup>.

##### **event.from**<sup>p980</sup>

Returns the previous value of [navigation.currentEntry](#)<sup>p958</sup>, before the current entry changed.

If [navigationType](#)<sup>p980</sup> is null or "[reload](#)<sup>p954</sup>", then this value will be the same as [navigation.currentEntry](#)<sup>p958</sup>. In that case, the event signifies that the contents of the entry changed, even if we did not move to a new entry or replace the current one.

The **navigationType** and **from** attributes must return the values they were initialized to.

### 7.2.7.2 The [PopStateEvent](#)<sup>p981</sup> interface §<sup>p98</sup><sub>1</sub>

IDL [Exposed=Window]

```
interface PopStateEvent : Event {
  constructor(DOMString type, optional PopStateEventInit eventInitDict = {});

  readonly attribute any state;
  readonly attribute boolean hasUAVisualTransition;
};

dictionary PopStateEventInit : EventInit {
  any state = null;
  boolean hasUAVisualTransition = false;
};
```

#### For web developers (non-normative)

##### [event.state](#)<sup>p981</sup>

Returns a copy of the information that was provided to [pushState\(\)](#)<sup>p946</sup> or [replaceState\(\)](#)<sup>p946</sup>.

##### [event.hasUAVisualTransition](#)<sup>p981</sup>

Returns true if the user agent performed a visual transition for this navigation before dispatching this event. If true, the best user experience will be given if the author synchronously updates the DOM to the post-navigation state.

The **state** attribute must return the value it was initialized to. It represents the context information for the event, or null, if the state represented is the initial state of the [Document](#)<sup>p130</sup>.

The **hasUAVisualTransition** attribute must return the value it was initialized to.

### 7.2.7.3 The [HashChangeEvent](#)<sup>p981</sup> interface §<sup>p98</sup><sub>1</sub>

IDL [Exposed=Window]

```
interface HashChangeEvent : Event {
  constructor(DOMString type, optional HashChangeEventInit eventInitDict = {});

  readonly attribute USVString oldURL;
  readonly attribute USVString newURL;
};

dictionary HashChangeEventInit : EventInit {
  USVString oldURL = "";
  USVString newURL = "";
};
```

#### For web developers (non-normative)

##### [event.oldURL](#)<sup>p981</sup>

Returns the [URL](#) of the [session history entry](#)<sup>p1005</sup> that was previously current.

##### [event.newURL](#)<sup>p981</sup>

Returns the [URL](#) of the [session history entry](#)<sup>p1005</sup> that is now current.

The **oldURL** attribute must return the value it was initialized to. It represents context information for the event, specifically the URL of the [session history entry](#)<sup>p1005</sup> that was traversed from.

The **newURL** attribute must return the value it was initialized to. It represents context information for the event, specifically the URL of the [session history entry](#)<sup>p1005</sup> that was traversed to.

#### 7.2.7.4 The [PageSwapEvent](#)<sup>p982</sup> interface §<sup>p98</sup><sub>2</sub>

```
IDL [Exposed=Window]
interface PageSwapEvent : Event {
  constructor(DOMString type, optional PageSwapEventInit eventInitDict = {});
  readonly attribute NavigationActivation? activation;
  readonly attribute ViewTransition? viewTransition;
};

dictionary PageSwapEventInit : EventInit {
  NavigationActivation? activation = null;
  ViewTransition? viewTransition = null;
};
```

##### For web developers (non-normative)

###### [event.activation](#)<sup>p982</sup>

A [NavigationActivation](#)<sup>p969</sup> object representing the destination and type of the cross-document navigation. This would be null for cross-origin navigations.

###### [event.activation](#)<sup>p982</sup>.[entry](#)<sup>p969</sup>

A [NavigationHistoryEntry](#)<sup>p956</sup>, representing the [Document](#)<sup>p130</sup> that is about to become active.

###### [event.activation](#)<sup>p982</sup>.[from](#)<sup>p969</sup>

A [NavigationHistoryEntry](#)<sup>p956</sup>, equivalent to the value of the [navigation.currentEntry](#)<sup>p958</sup> property at the moment the event is fired.

###### [event.activation](#)<sup>p982</sup>.[navigationType](#)<sup>p969</sup>

One of "[push](#)<sup>p953</sup>", "[replace](#)<sup>p953</sup>", "[reload](#)<sup>p954</sup>", or "[traverse](#)<sup>p954</sup>", indicating what type of navigation that is about to result in a page swap.

###### [event.viewTransition](#)<sup>p982</sup>

Returns the [ViewTransition](#) object that represents an outbound cross-document view transition, if such transition is active when the event is fired. Otherwise, returns null.

The **activation** and **viewTransition** attributes must return the values they were initialized to.

#### 7.2.7.5 The [PageRevealEvent](#)<sup>p982</sup> interface §<sup>p98</sup><sub>2</sub>

```
IDL [Exposed=Window]
interface PageRevealEvent : Event {
  constructor(DOMString type, optional PageRevealEventInit eventInitDict = {});
  readonly attribute ViewTransition? viewTransition;
};

dictionary PageRevealEventInit : EventInit {
  ViewTransition? viewTransition = null;
};
```

##### For web developers (non-normative)

###### [event.viewTransition](#)<sup>p982</sup>

Returns the [ViewTransition](#) object that represents an inbound cross-document view transition, if such transition is active when the event is fired. Otherwise, returns null.

The **viewTransition** attribute must return the value it was initialized to.

### 7.2.7.6 The `PageTransitionEvent`<sup>p983</sup> interface §<sup>p98</sup><sub>3</sub>

```
IDL [Exposed=Window]
interface PageTransitionEvent : Event {
  constructor(DOMString type, optional PageTransitionEventInit eventInitDict = {});

  readonly attribute boolean persisted;
};

dictionary PageTransitionEventInit : EventInit {
  boolean persisted = false;
};
```

#### For web developers (non-normative)

##### `event.persisted`<sup>p983</sup>

For the `pageshow`<sup>p1472</sup> event, returns false if the page is newly being loaded (and the `load`<sup>p1471</sup> event will fire). Otherwise, returns true.

For the `pagehide`<sup>p1472</sup> event, returns false if the page is going away for the last time. Otherwise, returns true, meaning that the page might be reused if the user navigates back to this page (if the `Document`<sup>p130</sup>'s `salvageable`<sup>p1064</sup> state stays true).

Things that can cause the page to be unsalvageable include:

- The user agent decided to not keep the `Document`<sup>p130</sup> alive in a `session history entry`<sup>p1005</sup> after `unload`<sup>p1064</sup>
- Having `iframe`<sup>p390</sup>s that are not `salvageable`<sup>p1064</sup>
- Active `WebSocket` objects
- [Aborting a Document](#)<sup>p1067</sup>

The `persisted` attribute must return the value it was initialized to. It represents the context information for the event.

To **fire a page transition event** named `eventName` at a `Window`<sup>p922</sup> window with a boolean `persisted`, [fire an event](#) named `eventName` at `window`, using `PageTransitionEvent`<sup>p983</sup>, with the `persisted`<sup>p983</sup> attribute initialized to `persisted`, the `cancelable` attribute initialized to true, the `bubbles` attribute initialized to true, and `legacy target override flag` set.

#### Note

*The values for `cancelable` and `bubbles` don't make any sense, since canceling the event does nothing and it's not possible to bubble past the `Window`<sup>p922</sup> object. They are set to true for historical reasons.*

### 7.2.7.7 The `BeforeUnloadEvent`<sup>p983</sup> interface §<sup>p98</sup><sub>3</sub>

```
IDL [Exposed=Window]
interface BeforeUnloadEvent : Event {
  attribute DOMString returnValue;
};
```

#### Note

*There are no `BeforeUnloadEvent`<sup>p983</sup>-specific initialization methods.*

The `BeforeUnloadEvent`<sup>p983</sup> interface is a legacy interface which allows [checking if unloading is canceled](#)<sup>p1025</sup> to be controlled not only by canceling the event, but by setting the `returnValue`<sup>p983</sup> attribute to a value besides the empty string. Authors should use the `preventDefault()` method, or other means of canceling events, instead of using `returnValue`<sup>p983</sup>.

The `returnValue` attribute controls the process of [checking if unloading is canceled](#)<sup>p1025</sup>. When the event is created, the attribute must be set to the empty string. On getting, it must return the last value it was set to. On setting, the attribute must be set to the new value.

## Note

This attribute is a DOMString only for historical reasons. Any value besides the empty string will be treated as a request to ask the user for confirmation.

### 7.2.8 The `NotRestoredReasons`<sup>p984</sup> interface §<sup>p98</sup><sub>4</sub>

```
IDL
[Exposed=Window]
interface NotRestoredReasonDetails {
  readonly attribute DOMString reason;
  [Default] object toJSON();
};

[Exposed=Window]
interface NotRestoredReasons {
  readonly attribute DOMString? src;
  readonly attribute DOMString? id;
  readonly attribute DOMString? name;
  readonly attribute DOMString? url;
  readonly attribute FrozenArray<NotRestoredReasonDetails>? reasons;
  readonly attribute FrozenArray<NotRestoredReasons>? children;
  [Default] object toJSON();
};
```

For web developers (non-normative)

#### `notRestoredReasonDetails.reason`<sup>p984</sup>

Returns a string that explains the reason that prevented the document from [being served from back/forward cache](#)<sup>p1006</sup>. See the definition of [bfcache blocking details](#)<sup>p131</sup> for the possible string values.

#### `notRestoredReasons.src`<sup>p987</sup>

Returns the `src`<sup>p391</sup> attribute of the document's [node navigable](#)<sup>p989</sup>'s [container](#)<sup>p991</sup> if it is an [iframe](#)<sup>p390</sup> element. This can be null if not set or if it is not an [iframe](#)<sup>p390</sup> element.

#### `notRestoredReasons.id`<sup>p987</sup>

Returns the `id`<sup>p154</sup> attribute of the document's [node navigable](#)<sup>p989</sup>'s [container](#)<sup>p991</sup> if it is an [iframe](#)<sup>p390</sup> element. This can be null if not set or if it is not an [iframe](#)<sup>p390</sup> element.

#### `notRestoredReasons.name`<sup>p987</sup>

Returns the `name`<sup>p395</sup> attribute of the document's [node navigable](#)<sup>p989</sup>'s [container](#)<sup>p991</sup> if it is an [iframe](#)<sup>p390</sup> element. This can be null if not set or if it is not an [iframe](#)<sup>p390</sup> element.

#### `notRestoredReasons.url`<sup>p987</sup>

Returns the document's URL, or null if the document is in a cross-origin [iframe](#)<sup>p390</sup>. This is reported in addition to `src`<sup>p987</sup> because it is possible [iframe](#)<sup>p390</sup> navigated since the original `src`<sup>p391</sup> was set.

#### `notRestoredReasons.reasons`<sup>p987</sup>

Returns an array of [NotRestoredReasonDetails](#)<sup>p984</sup> for the document. This is null if the document is in a cross-origin [iframe](#)<sup>p390</sup>.

#### `notRestoredReasons.children`<sup>p987</sup>

Returns an array of [NotRestoredReasons](#)<sup>p984</sup> that are for the document's children. This is null if the document is in a cross-origin [iframe](#)<sup>p390</sup>.

A [NotRestoredReasonDetails](#)<sup>p984</sup> object has a **backing struct**, a [not restored reason details](#)<sup>p985</sup> or null, initially null.

The `reason` getter steps are to return [this's backing struct](#)<sup>p984</sup>'s `reason`<sup>p985</sup>.

To create a [NotRestoredReasonDetails](#) object given a [not restored reason details](#)<sup>p985</sup> `backingStruct` and a [realm](#) `realm`:

1. Let `notRestoredReasonDetails` be a new [NotRestoredReasonDetails](#)<sup>p984</sup> object created in `realm`.
2. Set `notRestoredReasonDetails`'s [backing struct](#)<sup>p984</sup> to `backingStruct`.

3. Return *notRestoredReasonDetails*.

A **not restored reason details** is a [struct](#) with the following [items](#):

- **reason**, a string, initially empty.

The [reason](#)<sup>p985</sup> is a string that represents the reason that prevented the page from being restored from [back/forward cache](#)<sup>p1006</sup>. The string is one of the following:

**"fetch"**

While [unloading](#)<sup>p1064</sup>, a fetch initiated by this [Document](#)<sup>p130</sup> was still ongoing and was canceled, so the page was not in a state that could be stored in the [back/forward cache](#)<sup>p1006</sup>.

**"navigation-failure"**

The original navigation that created this [Document](#)<sup>p130</sup> errored, so storing the resulting error document in the [back/forward cache](#)<sup>p1006</sup> was prevented.

**"parser-aborted"**

The [Document](#)<sup>p130</sup> never finished its initial HTML parsing, so storing the unfinished document in the [back/forward cache](#)<sup>p1006</sup> was prevented.

**"websocket"**

While [unloading](#)<sup>p1064</sup>, an open [WebSocket](#) connection was shut down, so the page was not in a state that could be stored in the [back/forward cache](#)<sup>p1006</sup>. [\[WEBSOCKETS\]](#)<sup>p1484</sup>

**"lock"**

While [unloading](#)<sup>p1064</sup>, held [locks](#) and [lock requests](#) were terminated, so the page was not in a state that could be stored in the [back/forward cache](#)<sup>p1006</sup>. [\[WEBLOCKS\]](#)<sup>p1484</sup>

**"masked"**

This [Document](#)<sup>p130</sup> has children that are in a cross-origin [iframe](#)<sup>p390</sup>, and they prevented [back/forward cache](#)<sup>p1006</sup>; or this [Document](#)<sup>p130</sup> could not be [back/forward cached](#)<sup>p1006</sup> for user agent-specific reasons, and the user agent has chosen not to use one of the more specific reasons from the list of [user-agent specific blocking reasons](#)<sup>p985</sup>.

In addition to the list above, a user agent might choose to expose a reason that prevented the page from being restored from [back/forward cache](#) for **user-agent specific blocking reasons**. These are one of the following strings:

**"audio-capture"**

The [Document](#)<sup>p130</sup> requested audio capture permission by using *Media Capture and Streams*'s [getUserMedia\(\)](#) with audio. [\[MEDIASTREAM\]](#)<sup>p1480</sup>

**"background-work"**

The [Document](#)<sup>p130</sup> requested background work by calling [SyncManager](#)'s [register\(\)](#) method, [PeriodicSyncManager](#)'s [register\(\)](#) method, or [BackgroundFetchManager](#)'s [fetch\(\)](#) method.

**"broadcastchannel-message"**

While the page was stored in [back/forward cache](#)<sup>p1006</sup>, a [BroadcastChannel](#)<sup>p1209</sup> connection on the page received a message and [message](#)<sup>p1471</sup> event was fired.

**"idbversionchangeevent"**

The [Document](#)<sup>p130</sup> had a pending [IDBVersionChangeEvent](#) while [unloading](#)<sup>p1064</sup>. [\[INDEXEDDB\]](#)<sup>p1478</sup>

**"idledetector"**

The [Document](#)<sup>p130</sup> had an active [IdleDetector](#) while [unloading](#)<sup>p1064</sup>.

**"keyboardlock"**

While [unloading](#)<sup>p1064</sup>, keyboard lock was still active because [Keyboard](#)'s [lock\(\)](#) method was called.

**"mediastream"**

A [MediaStreamTrack](#) was in the [live state](#) upon [unloading](#)<sup>p1064</sup>. [\[MEDIASTREAM\]](#)<sup>p1480</sup>

**"midi"**

The [Document](#)<sup>p130</sup> requested a MIDI permission by calling [navigator.requestMIDIAccess\(\)](#).

**"modals"**

[User prompts](#)<sup>p1167</sup> were shown while [unloading](#)<sup>p1064</sup>.

### "navigating"

While [unloading](#)<sup>p1064</sup>, loading was still ongoing, and so the [Document](#)<sup>p130</sup> was not in a state that could be stored in [back/forward cache](#)<sup>p1006</sup>.

### "navigation-canceled"

The navigation request was canceled by calling [window.stop\(\)](#)<sup>p928</sup> and the page was not in a state to be stored in [back/forward cache](#).

### "non-trivial-browsing-context-group"

The [browsing context group](#)<sup>p1002</sup> of this [Document](#)<sup>p130</sup> had more than one [top-level browsing context](#)<sup>p1001</sup>.

### "otpcredential"

The [Document](#)<sup>p130</sup> created an [OTPCredential](#).

### "outstanding-network-request"

While [unloading](#)<sup>p1064</sup>, the [Document](#)<sup>p130</sup> had outstanding network requests and was not in a state that could be stored in [back/forward cache](#)<sup>p1006</sup>.

### "paymentrequest"

The [Document](#)<sup>p130</sup> had an active [PaymentRequest](#) while [unloading](#)<sup>p1064</sup>. [\[PAYMENTREQUEST\]](#)<sup>p1480</sup>

### "pictureinpicturewindow"

The [Document](#)<sup>p130</sup> had an active [PictureInPictureWindow](#) while [unloading](#)<sup>p1064</sup>. [\[PICTUREINPICTURE\]](#)<sup>p1480</sup>

### "plugins"

The [Document](#)<sup>p130</sup> contained [plugins](#)<sup>p47</sup>.

### "request-method-not-get"

The [Document](#)<sup>p130</sup> was created from an HTTP request whose [method](#) was not `GET`. [\[FETCH\]](#)<sup>p1478</sup>

### "response-auth-required"

The [Document](#)<sup>p130</sup> was created from an HTTP response that required HTTP authentication.

### "response-cache-control-no-store"

The [Document](#)<sup>p130</sup> was created from an HTTP response whose [`Cache-Control`](#) header included the "no-store" token. [\[HTTP\]](#)<sup>p1478</sup>

### "response-cache-control-no-cache"

The [Document](#)<sup>p130</sup> was created from an HTTP response whose [`Cache-Control`](#) header included the "no-cache" token. [\[HTTP\]](#)<sup>p1478</sup>

### "response-keep-alive"

The [Document](#)<sup>p130</sup> was created from an HTTP response that contained a [`Keep-Alive`](#) header.

### "response-scheme-not-http-or-https"

The [Document](#)<sup>p130</sup> was created from a response whose [URL's scheme](#) was not an [HTTP\(S\) scheme](#). [\[FETCH\]](#)<sup>p1478</sup>

### "response-status-not-ok"

The [Document](#)<sup>p130</sup> was created from an HTTP response whose [status](#) was not an [ok status](#). [\[FETCH\]](#)<sup>p1478</sup>

### "rtc"

While [unloading](#)<sup>p1064</sup>, a [RTCPeerConnection](#) or [RTCDataChannel](#) was shut down, so the page was not in a state that could be stored in the [back/forward cache](#)<sup>p1006</sup>. [\[WEBRTC\]](#)<sup>p1484</sup>

### "sensors"

The [Document](#)<sup>p130</sup> [requested sensor access](#).

### "serviceworker-added"

The [Document](#)<sup>p130</sup>'s [service worker client](#) started to be [controlled](#) by a [ServiceWorker](#) while the page was in [back/forward cache](#)<sup>p1006</sup>. [\[SW\]](#)<sup>p1482</sup>

### "serviceworker-claimed"

The [Document](#)<sup>p130</sup>'s [service worker client's active service worker](#)<sup>p1076</sup> was claimed while the page was in [back/forward cache](#)<sup>p1006</sup>. [\[SW\]](#)<sup>p1482</sup>

### "serviceworker-postmessage"

The [Document](#)<sup>p130</sup>'s [service worker client's active service worker](#)<sup>p1076</sup> received a message while the page was in [back/forward cache](#)<sup>p1006</sup>. [\[SW\]](#)<sup>p1482</sup>

### "serviceworker-version-activated"

The [Document](#)<sup>p130</sup>'s [service worker client](#)'s [active service worker](#)<sup>p1076</sup>'s version was activated while the page was in [back/forward cache](#)<sup>p1006</sup>. [[SW](#)]<sup>p1482</sup>

### "serviceworker-unregistered"

The [Document](#)<sup>p130</sup>'s [service worker client](#)'s [active service worker](#)<sup>p1076</sup>'s [service worker registration](#) was [unregistered](#) while the page was in [back/forward cache](#)<sup>p1006</sup>. [[SW](#)]<sup>p1482</sup>

### "sharedworker"

This [Document](#)<sup>p130</sup> was in the [owner set](#)<sup>p1228</sup> of a [SharedWorkerGlobalScope](#)<sup>p1230</sup>.

### "smartcardconnection"

The [Document](#)<sup>p130</sup> had an active [SmartCardConnection](#) while [unloading](#)<sup>p1064</sup>.

### "speechrecognition"

The [Document](#)<sup>p130</sup> had an active [SpeechRecognition](#) while [unloading](#)<sup>p1064</sup>.

### "storageaccess"

The [Document](#)<sup>p130</sup> requested storage access permission by using the Storage Access API.

### "unload-listener"

The [Document](#)<sup>p130</sup> registered an [event listener](#) for the [unload](#)<sup>p1472</sup> event.

### "video-capture"

The [Document](#)<sup>p130</sup> requested video capture permission by using *Media Capture and Streams*'s [getUserMedia\(\)](#) with video. [[MEDIASTREAM](#)]<sup>p1480</sup>

### "webhid"

The [Document](#)<sup>p130</sup> called the WebHID API's [requestDevice\(\)](#) method.

### "webshare"

The [Document](#)<sup>p130</sup> used the Web Share API's [navigator.share\(\)](#) method.

### "webtransport"

While [unloading](#)<sup>p1064</sup>, an open [WebTransport](#) connection was shut down, so the page was not in a state that could be stored in the [back/forward cache](#)<sup>p1006</sup>. [[WEBTRANSPORT](#)]<sup>p1484</sup>

### "webxrdevice"

The [Document](#)<sup>p130</sup> created a [XRSystem](#).

A [NotRestoredReasons](#)<sup>p984</sup> object has a **backing struct**, a [not restored reasons](#)<sup>p988</sup> or null, initially null.

A [NotRestoredReasons](#)<sup>p984</sup> object has a **reasons array**, a [FrozenArray](#)<[NotRestoredReasonDetails](#)<sup>p984</sup>> or null, initially null.

A [NotRestoredReasons](#)<sup>p984</sup> object has a **children array**, a [FrozenArray](#)<[NotRestoredReasons](#)<sup>p984</sup>> or null, initially null.

The **src** getter steps are to return [this](#)'s [backing struct](#)<sup>p987</sup>'s [src](#)<sup>p988</sup>.

The **id** getter steps are to return [this](#)'s [backing struct](#)<sup>p987</sup>'s [id](#)<sup>p988</sup>.

The **name** getter steps are to return [this](#)'s [backing struct](#)<sup>p987</sup>'s [name](#)<sup>p988</sup>.

The **url** getter steps are:

1. If [this](#)'s [backing struct](#)<sup>p987</sup>'s [URL](#)<sup>p988</sup> is null, then return null.
2. Return [this](#)'s [backing struct](#)<sup>p987</sup>'s [URL](#)<sup>p988</sup>, [serialized](#).

The **reasons** getter steps are to return [this](#)'s [reasons array](#)<sup>p987</sup>.

The **children** getter steps are to return [this](#)'s [children array](#)<sup>p987</sup>.

To **create a NotRestoredReasons object** given a [not restored reasons](#)<sup>p988</sup> *backingStruct* and a [realm](#) *realm*:

1. Let *notRestoredReasons* be a new [NotRestoredReasons](#)<sup>p984</sup> object created in *realm*.

2. Set *notRestoredReasons*'s [backing\\_struct](#)<sup>p987</sup> to *backingStruct*.
3. If *backingStruct*'s [reasons](#)<sup>p988</sup> is null, set *notRestoredReasons*'s [reasons\\_array](#)<sup>p987</sup> to null.
4. Otherwise:
  1. Let *reasonsArray* be an empty [list](#).
  2. [For each](#) *reason* of *backingStruct*'s [reasons](#)<sup>p988</sup>:
    1. [Create a NotRestoredReasonDetails object](#)<sup>p984</sup> given *reason* and *realm*, and [append](#) it to *reasonsArray*.
  3. Set *notRestoredReasons*'s [reasons\\_array](#)<sup>p987</sup> to the result of [creating a frozen array](#) given *reasonsArray*.
5. If *backingStruct*'s [children](#)<sup>p988</sup> is null, set *notRestoredReasons*'s [children\\_array](#)<sup>p987</sup> to null.
6. Otherwise:
  1. Let *childrenArray* be an empty [list](#).
  2. [For each](#) *child* of *backingStruct*'s [children](#)<sup>p988</sup>:
    1. [Create a NotRestoredReasons object](#)<sup>p987</sup> given *child* and *realm* and [append](#) it to *childrenArray*.
  3. Set *notRestoredReasons*'s [children\\_array](#)<sup>p987</sup> to the result of [creating a frozen array](#) given *childrenArray*.
7. Return *notRestoredReasons*.

A **not restored reasons** is a [struct](#) with the following [items](#):

- **src**, a string or null, initially null.
- **id**, a string or null, initially null.
- **name**, a string or null, initially null.
- **url**, a [URL](#) or null, initially null.
- **reasons**, null or a [list](#) of [not restored reason details](#)<sup>p985</sup>, initially null.
- **children**, null or a [list](#) of [not restored reasons](#)<sup>p988</sup>, initially null.

A **Document's not restored reasons** is its [node navigable](#)<sup>p989</sup>'s [active session history entry](#)<sup>p989</sup>'s [document state](#)<sup>p1005</sup>'s [not restored reasons](#)<sup>p1007</sup>, if [Document](#)<sup>p130</sup>'s [node navigable](#)<sup>p989</sup> is a [top-level traversable](#)<sup>p990</sup>; otherwise null.

## 7.3 Infrastructure for sequences of documents §<sup>p98</sup><sub>8</sub>

This standard contains several related concepts for grouping sequences of documents. As a brief, non-normative summary:

- [Navigables](#)<sup>p989</sup> are a user-facing representation of a sequence of documents, i.e., they represent something that can be navigated between documents. Typical examples are tabs or windows in a web browser, or [iframe](#)<sup>p390</sup>s, or [frame](#)<sup>p1433</sup>s in a [frameset](#)<sup>p1433</sup>.
- [Traversable navigables](#)<sup>p990</sup> are a special type of navigable which control the session history of themselves and of their descendant navigables. That is, in addition to their own series of documents, they represent a tree of further series of documents, plus the ability to linearly traverse back and forward through a flattened view of this tree.
- [Browsing contexts](#)<sup>p998</sup> are a developer-facing representation of a series of documents. They correspond 1:1 with [WindowProxy](#)<sup>p934</sup> objects. Each navigable can present a series of browsing contexts, with [switches](#)<sup>p905</sup> between those browsing contexts occurring under certain well-defined circumstances.

Most of this standard works in the language of navigables, but certain APIs expose the existence of browsing context switches, and so some parts of the standard need to work in terms of browsing contexts.

### 7.3.1 Navigables §<sup>p98</sup><sub>9</sub>

A **navigable** presents a [Document](#)<sup>p130</sup> to the user via its [active session history entry](#)<sup>p989</sup>. Each navigable has:

- An **id**, a [new unique internal value](#)<sup>p96</sup>.
- A **parent**, a [navigable](#)<sup>p989</sup> or null.
- A **current session history entry**, a [session history entry](#)<sup>p1005</sup>.

This can only be modified within the [session history traversal queue](#)<sup>p990</sup> of the parent [traversable navigable](#)<sup>p990</sup>.

- An **active session history entry**, a [session history entry](#)<sup>p1005</sup>.

This can only be modified from the event loop of the [active session history entry](#)<sup>p989</sup>'s [document](#)<sup>p1005</sup>.

- An **is closing** boolean, initially false.

#### Note

*This is only ever set to true for [top-level traversable navigables](#)<sup>p990</sup>.*

- An **is delaying load events** boolean, initially false.

#### Note

*This is only ever set to true in cases where the navigable's [parent](#)<sup>p989</sup> is non-null.*

The [current session history entry](#)<sup>p989</sup> and the [active session history entry](#)<sup>p989</sup> are usually the same, but they get out of sync when:

- Synchronous navigations are performed. This causes the [active session history entry](#)<sup>p989</sup> to temporarily step ahead of the [current session history entry](#)<sup>p989</sup>.
- A non-displayable, non-error response is received when [applying the history step](#)<sup>p1041</sup>. This updates the [current session history entry](#)<sup>p989</sup> but leaves the [active session history entry](#)<sup>p989</sup> as-is.

A [navigable](#)<sup>p989</sup>'s **active document** is its [active session history entry](#)<sup>p989</sup>'s [document](#)<sup>p1005</sup>.

#### Note

*This can be safely read from within the [session history traversal queue](#)<sup>p990</sup> of the navigable's [top-level traversable](#)<sup>p990</sup>. Although a [navigable](#)<sup>p989</sup>'s [active history entry](#)<sup>p989</sup> can change synchronously, the new entry will always have the same [Document](#)<sup>p130</sup>.*

A [navigable](#)<sup>p989</sup>'s **active browsing context** is its [active document](#)<sup>p989</sup>'s [browsing context](#)<sup>p999</sup>. If this [navigable](#)<sup>p989</sup> is a [traversable navigable](#)<sup>p990</sup>, then its [active browsing context](#)<sup>p989</sup> will be a [top-level browsing context](#)<sup>p1001</sup>.

A [navigable](#)<sup>p989</sup>'s **active WindowProxy** is its [active browsing context](#)<sup>p989</sup>'s associated [WindowProxy](#)<sup>p934</sup>.

A [navigable](#)<sup>p989</sup>'s **active window** is its [active WindowProxy](#)<sup>p989</sup>'s [\[\[Window\]\]](#)<sup>p934</sup>.

#### Note

*This will always equal the navigable's [active document](#)<sup>p989</sup>'s [relevant global object](#)<sup>p1083</sup>; this is kept in sync by the [make active](#)<sup>p1051</sup> algorithm.*

A [navigable](#)<sup>p989</sup>'s **target name** is its [active session history entry](#)<sup>p989</sup>'s [document state](#)<sup>p1005</sup>'s [navigable target name](#)<sup>p1007</sup>.

To get the **node navigable** of a [node node](#), return the [navigable](#)<sup>p989</sup> whose [active document](#)<sup>p989</sup> is [node's node document](#), or null if there is no such [navigable](#)<sup>p989</sup>.

To **initialize the navigable** [navigable](#)<sup>p989</sup> [navigable](#), given a [document state](#)<sup>p1006</sup> [documentState](#) and an optional [navigable](#)<sup>p989</sup>-or-null [parent](#) (default null):

1. **Assert**: [documentState's document](#)<sup>p1006</sup> is non-null.

2. Let *entry* be a new [session history entry](#)<sup>p1005</sup>, with

[URL](#)<sup>p1005</sup>

*documentState*'s [document](#)<sup>p1006</sup>'s [URL](#)

[document state](#)<sup>p1005</sup>

*documentState*

#### Note

*The caller of this algorithm is responsible for initializing *entry*'s [step](#)<sup>p1005</sup>; it will be left as "pending" until that is complete.*

3. Set *navigable*'s [current session history entry](#)<sup>p989</sup> to *entry*.
4. Set *navigable*'s [active session history entry](#)<sup>p989</sup> to *entry*.
5. Set *navigable*'s [parent](#)<sup>p989</sup> to *parent*.

### 7.3.1.1 Traversable navigables §<sup>p99</sup><sub>0</sub>

A **traversable navigable** is a [navigable](#)<sup>p989</sup> that also controls which [session history entry](#)<sup>p1005</sup> should be the [current session history entry](#)<sup>p989</sup> and [active session history entry](#)<sup>p989</sup> for itself and its descendant [navigables](#)<sup>p989</sup>.

In addition to the properties of a [navigable](#)<sup>p989</sup>, a [traversable navigable](#)<sup>p990</sup> has:

- A **current session history step**, a number, initially 0.
- **Session history entries**, a [list](#) of [session history entries](#)<sup>p1005</sup>, initially a new [list](#).
- A **session history traversal queue**, a [session history traversal parallel queue](#)<sup>p1008</sup>, the result of [starting a new session history traversal parallel queue](#)<sup>p1008</sup>.
- A **running nested apply history step** boolean, initially false.
- A **system visibility state**, which is either "hidden" or "visible".

See the [page visibility](#)<sup>p826</sup> section for the requirements on this item.

To get the **traversable navigable** of a [navigable](#)<sup>p989</sup> *inputNavigable*:

1. Let *navigable* be *inputNavigable*.
2. While *navigable* is not a [traversable navigable](#)<sup>p990</sup>, set *navigable* to *navigable*'s [parent](#)<sup>p989</sup>.
3. Return *navigable*.

### 7.3.1.2 Top-level traversables §<sup>p99</sup><sub>0</sub>

A **top-level traversable** is a [traversable navigable](#)<sup>p990</sup> with a null [parent](#)<sup>p989</sup>.

#### Note

*Currently, all [traversable navigables](#)<sup>p990</sup> are [top-level traversables](#)<sup>p990</sup>. Future proposals envision introducing non-top-level traversables.*

A user agent holds a **top-level traversable set** (a [set](#) of [top-level traversables](#)<sup>p990</sup>). These are typically presented to the user in the form of browser windows or browser tabs.

To get the **top-level traversable** of a [navigable](#)<sup>p989</sup> *inputNavigable*:

1. Let *navigable* be *inputNavigable*.
2. While *navigable*'s [parent](#)<sup>p989</sup> is not null, set *navigable* to *navigable*'s [parent](#)<sup>p989</sup>.
3. Return *navigable*.

To **create a new top-level traversable** given a [browsing context](#)<sup>p998</sup>-or-null *opener*, a string *targetName*, and an optional [navigable](#)<sup>p989</sup> *openerNavigableForWebDriver*:

1. Let *document* be null.
2. If *opener* is null, then set *document* to the second return value of [creating a new top-level browsing context and document](#)<sup>p1000</sup>.
3. Otherwise, set *document* to the second return value of [creating a new auxiliary browsing context and document](#)<sup>p1000</sup> given *opener*.
4. Let *documentState* be a new [document state](#)<sup>p1006</sup>, with
  - [document](#)<sup>p1006</sup>  
*document*
  - [initiator origin](#)<sup>p1006</sup>  
null if *opener* is null; otherwise, *document*'s [origin](#)  
[origin](#)<sup>p1006</sup>
  - document*'s [origin](#)
  - [navigable target name](#)<sup>p1007</sup>  
*targetName*
  - [about base URL](#)<sup>p1007</sup>  
*document*'s [about base URL](#)<sup>p131</sup>
5. Let *traversable* be a new [traversable navigable](#)<sup>p990</sup>.
6. [Initialize the navigable](#)<sup>p989</sup> *traversable* given *documentState*.
7. Let *initialHistoryEntry* be *traversable*'s [active session history entry](#)<sup>p989</sup>.
8. Set *initialHistoryEntry*'s [step](#)<sup>p1005</sup> to 0.
9. [Append](#) *initialHistoryEntry* to *traversable*'s [session history entries](#)<sup>p990</sup>.
10. If *opener* is non-null, then [legacy-clone a traversable storage shed](#) given *opener*'s [top-level traversable](#)<sup>p998</sup> and *traversable*.  
[STORAGE]<sup>p1482</sup>
11. [Append](#) *traversable* to the user agent's [top-level traversable set](#)<sup>p990</sup>.
12. Invoke [WebDriver BiDi navigable created](#) with *traversable* and *openerNavigableForWebDriver*.
13. Return *traversable*.

To **create a fresh top-level traversable** given a [URL](#) *initialNavigationURL* and an optional [POST resource](#)<sup>p1007</sup>-or-null *initialNavigationPostResource* (default null):

1. Let *traversable* be the result of [creating a new top-level traversable](#)<sup>p991</sup> given null and the empty string.
2. [Navigate](#)<sup>p1014</sup> *traversable* to *initialNavigationURL* using *traversable*'s [active document](#)<sup>p989</sup>, with [documentResource](#)<sup>p1014</sup> set to *initialNavigationPostResource*.

#### Note

*We treat these initial navigations as traversable navigating itself, which will ensure all relevant security checks pass.*

3. Return *traversable*.

### 7.3.1.3 Child navigables <sup>p99</sup><sub>1</sub>

Certain elements (for example, [iframe](#)<sup>p390</sup> elements) can present a [navigable](#)<sup>p989</sup> to the user. These elements are called **navigable containers**.

Each [navigable container](#)<sup>p991</sup> has a **content navigable**, which is either a [navigable](#)<sup>p989</sup> or null. It is initially null.

The **container** of a [navigable](#)<sup>p989</sup> *navigable* is the [navigable container](#)<sup>p991</sup> whose [content navigable](#)<sup>p991</sup> is *navigable*, or null if there is no such element.

The **container document** of a [navigable<sup>p989</sup>](#) *navigable* is the result of running these steps:

1. If *navigable*'s [container<sup>p991</sup>](#) is null, then return null.
2. Return *navigable*'s [container<sup>p991</sup>](#)'s [node document](#).

**Note**

*This is equal to [navigable's container<sup>p991</sup>](#)'s [shadow-including root](#) as [navigable's container<sup>p991</sup>](#) has to be [connected](#).*

The **container document** of a [Document<sup>p130</sup>](#) *document* is the result of running these steps:

1. If *document*'s [node navigable<sup>p989</sup>](#) is null, then return null.
2. Return *document*'s [node navigable<sup>p989</sup>](#)'s [container document<sup>p992</sup>](#).

A [navigable<sup>p989</sup>](#) *navigable* is a **child navigable** of another navigable *potentialParent* when *navigable*'s [parent<sup>p989</sup>](#) is *potentialParent*. We can also just say that a [navigable<sup>p989</sup>](#) "is a [child navigable<sup>p992</sup>](#)", which means that its [parent<sup>p989</sup>](#) is non-null.

**Note**

*All [child navigables<sup>p992</sup>](#) are the [content navigable<sup>p991</sup>](#) of their [container<sup>p991</sup>](#).*

The **content document** of a [navigable container<sup>p991</sup>](#) *container* is the result of running these steps:

1. If *container*'s [content navigable<sup>p991</sup>](#) is null, then return null.
2. Let *document* be *container*'s [content navigable<sup>p991</sup>](#)'s [active document<sup>p989</sup>](#).
3. If *document*'s [origin](#) and *container*'s [node document](#)'s [origin](#) are not [same origin-domain<sup>p899</sup>](#), then return null.
4. Return *document*.

The **content window** of a [navigable container<sup>p991</sup>](#) *container* is the result of running these steps:

1. If *container*'s [content navigable<sup>p991</sup>](#) is null, then return null.
2. Return *container*'s [content navigable<sup>p991</sup>](#)'s [active WindowProxy<sup>p989</sup>](#)'s object.

To **create a new child navigable**, given an element *element*:

1. Let *parentNavigable* be *element*'s [node navigable<sup>p989</sup>](#).
2. Let *group* be *element*'s [node document](#)'s [browsing context<sup>p999</sup>](#)'s [top-level browsing context<sup>p1001</sup>](#)'s [group<sup>p1002</sup>](#).
3. Let *browsingContext* and *document* be the result of [creating a new browsing context and document<sup>p999</sup>](#) given *element*'s [node document](#), *element*, and *group*.
4. Let *targetName* be null.
5. If *element* has a `name` content attribute, then set *targetName* to the value of that attribute.
6. Let *documentState* be a new [document state<sup>p1006</sup>](#), with
  - [document<sup>p1006</sup>](#)  
*document*
  - [initiator origin<sup>p1006</sup>](#)  
*document*'s [origin](#)
  - [origin<sup>p1006</sup>](#)  
*document*'s [origin](#)
  - [navigable target name<sup>p1007</sup>](#)  
*targetName*
  - [about base URL<sup>p1007</sup>](#)  
*document*'s [about base URL<sup>p131</sup>](#)
7. Let *navigable* be a new [navigable<sup>p989</sup>](#).
8. [Initialize the navigable<sup>p989</sup>](#) *navigable* given *documentState* and *parentNavigable*.

9. Set *element*'s [content navigable](#)<sup>p991</sup> to *navigable*.
10. Let *historyEntry* be *navigable*'s [active session history entry](#)<sup>p989</sup>.
11. Let *traversable* be *parentNavigable*'s [traversable navigable](#)<sup>p990</sup>.
12. [Append the following session history traversal steps](#)<sup>p1008</sup> to *traversable*:
  1. Let *parentDocState* be *parentNavigable*'s [active session history entry](#)<sup>p989</sup>'s [document state](#)<sup>p1005</sup>.
  2. Let *parentNavigableEntries* be the result of [getting session history entries](#)<sup>p1010</sup> for *parentNavigable*.
  3. Let *targetStepSHE* be the first [session history entry](#)<sup>p1005</sup> in *parentNavigableEntries* whose [document state](#)<sup>p1005</sup> equals *parentDocState*.
  4. Set *historyEntry*'s [step](#)<sup>p1005</sup> to *targetStepSHE*'s [step](#)<sup>p1005</sup>.
  5. Let *nestedHistory* be a new [nested history](#)<sup>p1007</sup> whose [id](#)<sup>p1007</sup> is *navigable*'s [id](#)<sup>p989</sup> and [entries list](#)<sup>p1007</sup> is « *historyEntry* ».
  6. [Append](#) *nestedHistory* to *parentDocState*'s [nested histories](#)<sup>p1007</sup>.
  7. [Update for navigable creation/destruction](#)<sup>p1040</sup> given *traversable*.
13. Invoke [WebDriver BiDi navigable created](#) with *traversable*.

#### 7.3.1.4 Jake diagrams <sup>p99</sup><sub>3</sub>

A useful method for visualizing sequences of documents, and in particular [navigables](#)<sup>p989</sup> and their [session history entries](#)<sup>p1005</sup>, is the **Jake diagram**. A typical Jake diagram is the following:

	0	1	2	3	4
top	/t-a		/t-a#foo		/t-b
frames[0]	/i-0-a	<b>/i-0-b</b>			
frames[1]	<b>/i-1-a</b>	/i-1-b			

Here, each numbered column denotes a possible value for the traversable's [session history step](#)<sup>p990</sup>. Each labeled row depicts a [navigable](#)<sup>p989</sup>, as it transitions between different URLs and documents. The first, labeled *top*, being the [top-level traversable](#)<sup>p990</sup>, and the others being [child navigables](#)<sup>p992</sup>. The documents are given by the background color of each cell, with a new background color indicating a new document in that [navigable](#)<sup>p989</sup>. The URLs are given by the text content of the cells; usually they are given as [relative URLs](#) for brevity, unless a cross-origin case is specifically under investigation. A given navigable might not exist at a given step, in which case the corresponding cells are empty. The bold-italic step number depicts the [current session history step](#)<sup>p990</sup> of the traversable, and all cells with bold-italic URLs represent the [current session history entry](#)<sup>p989</sup> for that row's navigable.

Thus, the above Jake diagram depicts the following sequence of events:

0. A [top-level traversable](#)<sup>p990</sup> is created, starting at the URL /t-a, with two [child navigables](#)<sup>p992</sup> starting at /i-0-a and /i-1-a respectively.
1. The first child navigable is [navigated](#)<sup>p1014</sup> to another document, with URL /i-0-b.
2. The second child navigable is [navigated](#)<sup>p1014</sup> to another document, with URL /i-1-b.
3. The top-level traversable is [navigated](#)<sup>p1014</sup> to the *same* document, updating its URL to /t-a#foo.
4. The top-level traversable is [navigated](#)<sup>p1014</sup> to another document, with URL /t-b. (Notice how this document, of course, does not carry over the old document's child navigables.)
5. The traversable was [traversed by a delta](#)<sup>p1028</sup> of -3, back to step 1.

[Jake diagrams](#)<sup>p993</sup> are a powerful tool for visualizing the interactions of multiple navigables, navigations, and traversals. They cannot capture every possible interaction — for example, they only work with a single level of nesting — but we will have occasion to use them to illustrate several complex situations throughout this standard.

## Note

[Jake diagrams](#)<sup>p993</sup> are named after their creator, the inimitable Jake Archibald.

### 7.3.1.5 Related navigable collections §<sup>p99</sup><sub>4</sub>

It is often helpful in this standard's algorithms to look at collections of [navigables](#)<sup>p989</sup> starting at a given [Document](#)<sup>p130</sup>. This section contains a curated set of algorithms for collecting those navigables.

## Note

The return values of these algorithms are ordered so that parents appears before their children. Callers rely on this ordering.

## Note

Starting with a [Document](#)<sup>p130</sup>, rather than a [navigable](#)<sup>p989</sup>, is generally better because it makes the caller cognizant of whether they are starting with a [fully active](#)<sup>p1003</sup> [Document](#)<sup>p130</sup> or not. Although non-[fully active](#)<sup>p1003</sup> [Document](#)<sup>p130</sup>s do have ancestor and descendant navigables, they often behave as if they don't (e.g., in the [window.parent](#)<sup>p931</sup> getter).

The **ancestor navigables** of a [Document](#)<sup>p130</sup> document are given by these steps:

1. Let *navigable* be document's [node navigable](#)<sup>p989</sup>'s [parent](#)<sup>p989</sup>.
2. Let *ancestors* be an empty list.
3. While *navigable* is not null:
  1. [Prepend](#) *navigable* to *ancestors*.
  2. Set *navigable* to *navigable*'s [parent](#)<sup>p989</sup>.
4. Return *ancestors*.

The **inclusive ancestor navigables** of a [Document](#)<sup>p130</sup> document are given by these steps:

1. Let *navigables* be document's [ancestor navigables](#)<sup>p994</sup>.
2. [Append](#) document's [node navigable](#)<sup>p989</sup> to *navigables*.
3. Return *navigables*.

The **descendant navigables** of a [Document](#)<sup>p130</sup> document are given by these steps:

1. Let *navigables* be new [list](#).
2. Let *navigableContainers* be a [list](#) of all [shadow-including descendants](#) of document that are [navigable containers](#)<sup>p991</sup>, in [shadow-including tree order](#).
3. [For each](#) *navigableContainer* of *navigableContainers*:
  1. If *navigableContainer*'s [content navigable](#)<sup>p991</sup> is null, then continue.
  2. [Extend](#) *navigables* with *navigableContainer*'s [content navigable](#)<sup>p991</sup>'s [active document](#)<sup>p989</sup>'s [inclusive descendant navigables](#)<sup>p994</sup>.
4. Return *navigables*.

The **inclusive descendant navigables** of a [Document](#)<sup>p130</sup> document are given by these steps:

1. Let *navigables* be « document's [node navigable](#)<sup>p989</sup> ».
2. [Extend](#) *navigables* with document's [descendant navigables](#)<sup>p994</sup>.
3. Return *navigables*.

## Note

These descendant-collecting algorithms are described as looking at the DOM tree of descendant [Document](#)<sup>p130</sup> objects. In reality, this is often not feasible since the DOM tree can be in another process from the caller of the algorithm. Instead, implementations generally replicate the appropriate trees across processes.

The **document-tree child navigables** of a [Document](#)<sup>p130</sup> document are given by these steps:

1. If document's [node navigable](#)<sup>p989</sup> is null, then return the empty list.
2. Let *navigables* be new [list](#).
3. Let *navigableContainers* be a [list](#) of all [descendants](#) of document that are [navigable containers](#)<sup>p991</sup>, in [tree order](#).
4. [For each](#) *navigableContainer* of *navigableContainers*:
  1. If *navigableContainer*'s [content navigable](#)<sup>p991</sup> is null, then [continue](#).
  2. [Append](#) *navigableContainer*'s [content navigable](#)<sup>p991</sup> to *navigables*.
5. Return *navigables*.

### 7.3.1.6 Navigable destruction §<sup>p99</sup><sub>5</sub>

To **destroy a child navigable** given a [navigable container](#)<sup>p991</sup> container:

1. Let *navigable* be container's [content navigable](#)<sup>p991</sup>.
2. If *navigable* is null, then return.
3. Set container's [content navigable](#)<sup>p991</sup> to null.
4. [Inform the navigation API about child navigable destruction](#)<sup>p968</sup> given *navigable*.
5. [Destroy a document and its descendants](#)<sup>p1066</sup> given *navigable*'s [active document](#)<sup>p989</sup>.
6. Let *parentDocState* be container's [node navigable](#)<sup>p989</sup>'s [active session history entry](#)<sup>p989</sup>'s [document state](#)<sup>p1005</sup>.
7. [Remove](#) the [nested history](#)<sup>p1007</sup> from *parentDocState*'s [nested histories](#)<sup>p1007</sup> whose [id](#)<sup>p1007</sup> equals *navigable*'s [id](#)<sup>p989</sup>.
8. Let *traversable* be container's [node navigable](#)<sup>p989</sup>'s [traversable navigable](#)<sup>p990</sup>.
9. [Append the following session history traversal steps](#)<sup>p1008</sup> to *traversable*:
  1. [Update for navigable creation/destruction](#)<sup>p1040</sup> given *traversable*.
10. Invoke [WebDriver BiDi navigable destroyed](#) with *navigable*.

To **destroy a top-level traversable<sup>p990</sup> traversable:**

1. Let *browsingContext* be traversable's [active browsing context](#)<sup>p989</sup>.
2. [For each](#) *historyEntry* in traversable's [session history entries](#)<sup>p990</sup> **in what order?**:
  1. Let *document* be *historyEntry*'s [document](#)<sup>p1005</sup>.
  2. If *document* is not null, then [destroy a document and its descendants](#)<sup>p1066</sup> given *document*.
3. [Remove](#)<sup>p1003</sup> *browsingContext*.
4. Remove *traversable* from the user interface (e.g., close or hide its tab in a tabbed browser).
5. [Remove](#) *traversable* from the user agent's [top-level traversable set](#)<sup>p990</sup>.
6. Invoke [WebDriver BiDi navigable destroyed](#) with *traversable*.

User agents may [destroy a top-level traversable](#)<sup>p995</sup> at any time (typically, [in response to user requests](#)<sup>p1069</sup>).

To **close a top-level traversable<sup>p990</sup> traversable:**

1. If *traversable*'s [is closing](#)<sup>p989</sup> is true, then return.
2. [Definitely close](#)<sup>p996</sup> *traversable*.

To **definitely close** a [top-level traversable](#)<sup>p990</sup> *traversable*:

1. Let *toUnload* be *traversable*'s [active document](#)<sup>p989</sup>'s [inclusive descendant navigables](#)<sup>p994</sup>.
2. If the result of [checking if unloading is canceled](#)<sup>p1025</sup> for *toUnload* is true, then return.
3. [Append the following session history traversal steps](#)<sup>p1008</sup> to *traversable*:
  1. Let *afterAllUnloads* be an algorithm step which [destroys](#)<sup>p995</sup> *traversable*.
  2. [Unload a document and its descendants](#)<sup>p1065</sup> given *traversable*'s [active document](#)<sup>p989</sup>, null, and *afterAllUnloads*.

#### Note

The [close](#)<sup>p995</sup> vs. [definitely close](#)<sup>p996</sup> separation allows other specifications to call [close](#)<sup>p995</sup> and have it be a no-op if the top-level traversable is already closing due to JavaScript code calling [window.close\(\)](#)<sup>p928</sup>.

### 7.3.1.7 Navigable target names <sup>p99</sup><sub>6</sub>

[Navigables](#)<sup>p989</sup> can be given [target names](#)<sup>p989</sup>, which are strings allowing certain APIs (such as [window.open\(\)](#)<sup>p926</sup> or the [a](#)<sup>p257</sup> element's [target](#)<sup>p303</sup> attribute) to target [navigations](#)<sup>p1014</sup> at that navigable.

A **valid navigable target name** is any string with at least one character that does not contain both an [ASCII tab or newline](#) and a U+003C (<), and it does not start with a U+005F (\_). (Names starting with a U+005F (\_) are reserved for special keywords.)

A **valid navigable target name or keyword** is any string that is either a [valid navigable target name](#)<sup>p996</sup> or that is an [ASCII case-insensitive](#) match for one of: `_blank`, `_self`, `_parent`, or `_top`.

These values have different meanings based on whether the page is sandboxed or not, as summarized in the following (non-normative) table. In this table, "current" means the [navigable](#)<sup>p989</sup> that the link or script is in, "parent" means the [parent](#)<sup>p989</sup> of the [navigable](#)<sup>p989</sup> that the link or script is in, "top" means the [top-level traversable](#)<sup>p990</sup> of the [navigable](#)<sup>p989</sup> that the link or script is in, "new" means a new [traversable navigable](#)<sup>p990</sup> with a null [parent](#)<sup>p989</sup> (which may use an [auxiliary browsing context](#)<sup>p999</sup>, subject to various user preferences and user agent policies), "none" means that nothing will happen, and "maybe new" means the same as "new" if the [allow-popups](#)<sup>p916</sup> keyword is also specified on the [sandbox](#)<sup>p395</sup> attribute (or if the user overrode the sandboxing), and the same as "none" otherwise.

Keyword	Ordinary effect	Effect in an <a href="#">iframe</a> <sup>p390</sup> with...	
		<code>sandbox=""</code>	<code>sandbox="allow-top-navigation"</code>
none specified, for links and form submissions	current	current	current
empty string	current	current	current
<code>_blank</code>	new	maybe new	maybe new
<code>_self</code>	current	current	current
<code>_parent</code> if there isn't a parent	current	current	current
<code>_parent</code> if parent is also top	parent/top	none	parent/top
<code>_parent</code> if there is one and it's not top	parent	none	none
<code>_top</code> if top is current	current	current	current
<code>_top</code> if top is not current	top	none	top
name that doesn't exist	new	maybe new	maybe new
name that exists and is a descendant	specified descendant	specified descendant	specified descendant
name that exists and is current	current	current	current
name that exists and is an ancestor that is top	specified ancestor	none	specified ancestor/top
name that exists and is an ancestor that is not top	specified ancestor	none	none
other name that exists with common top	specified	none	none
name that exists with different top, if <a href="#">familiar</a> <sup>p1002</sup> and <a href="#">one permitted sandboxed navigator</a> <sup>p914</sup>	specified	specified	specified

Keyword	Ordinary effect	Effect in an <a href="#">iframe</a> <sup>p390</sup> with...	
		<code>sandbox=""</code>	<code>sandbox="allow-top-navigation"</code>
name that exists with different top, if <a href="#">familiar</a> <sup>p1002</sup> but not <a href="#">one permitted sandboxed navigator</a> <sup>p914</sup>	specified	none	none
name that exists with different top, not <a href="#">familiar</a> <sup>p1002</sup>	new	maybe new	maybe new

Most of the restrictions on sandboxed browsing contexts are applied by other algorithms, e.g. the [navigation](#)<sup>p1014</sup> algorithm, not [the rules for choosing a navigable](#)<sup>p997</sup> given below.

**The rules for choosing a navigable**, given a string *name*, a [navigable](#)<sup>p989</sup> *currentNavigable*, and a boolean *noopener* are as follows:

1. Let *chosen* be null.
2. Let *windowType* be "existing or none".
3. Let *sandboxingFlagSet* be *currentNavigable*'s [active document](#)<sup>p989</sup>'s [active sandboxing flag set](#)<sup>p917</sup>.
4. If *name* is the empty string or an [ASCII case-insensitive](#) match for "\_self", then set *chosen* to *currentNavigable*.
5. Otherwise, if *name* is an [ASCII case-insensitive](#) match for "\_parent", set *chosen* to *currentNavigable*'s [parent](#)<sup>p989</sup>, if any, and *currentNavigable* otherwise.
6. Otherwise, if *name* is an [ASCII case-insensitive](#) match for "\_top", set *chosen* to *currentNavigable*'s [traversable navigable](#)<sup>p990</sup>.
7. Otherwise, if *name* is not an [ASCII case-insensitive](#) match for "\_blank", there exists a [navigable](#)<sup>p989</sup> whose [target name](#)<sup>p989</sup> is the same as *name*, *currentNavigable*'s [active browsing context](#)<sup>p989</sup> is [familiar with](#)<sup>p1002</sup> that [navigable](#)<sup>p989</sup>'s [active browsing context](#)<sup>p989</sup>, and the user agent determines that the two browsing contexts are related enough that it is ok if they reach each other, set *chosen* to that navigable. If there are multiple matching [navigables](#)<sup>p989</sup>, the user agent should pick one in some arbitrary consistent manner, such as the most recently opened, most recently focused, or more closely related, and set *chosen* to it.

This will be made more precise in [issue #313](#).

8. Otherwise, a new [top-level traversable](#)<sup>p990</sup> is being requested, and what happens depends on the user agent's configuration and abilities — it is determined by the rules given for the first applicable option from the following list:
  - ↪ If *currentNavigable*'s [active window](#)<sup>p989</sup> does not have [transient activation](#)<sup>p830</sup> and the user agent has been configured to not show popups (i.e., the user agent has a "popup blocker" enabled)
 

The user agent may inform the user that a popup has been blocked.
  - ↪ If *sandboxingFlagSet* has the [sandboxed auxiliary navigation browsing context flag](#)<sup>p915</sup> set
 

The user agent may report to a developer console that a popup has been blocked.
  - ↪ If the user agent has been configured such that in this instance it will create a new [top-level traversable](#)<sup>p990</sup>
    1. [Consume user activation](#)<sup>p831</sup> of *currentNavigable*'s [active window](#)<sup>p989</sup>.
    2. Set *windowType* to "new and unrestricted".
    3. Let *currentDocument* be *currentNavigable*'s [active document](#)<sup>p989</sup>.
    4. If *currentDocument*'s [opener policy](#)<sup>p131</sup>'s [value](#)<sup>p904</sup> is "same-origin<sup>p903</sup>" or "same-origin-plus-COEP<sup>p903</sup>", and *currentDocument*'s [origin](#) is not [same origin](#)<sup>p899</sup> with *currentDocument*'s [relevant settings object](#)<sup>p1083</sup>'s [top-level origin](#)<sup>p1076</sup>, then:
      1. Set *noopener* to true.
      2. Set *name* to "\_blank".
      3. Set *windowType* to "new with no opener".

#### Note

In the presence of an [opener policy](#)<sup>p904</sup>, nested documents that are cross-origin with their top-level browsing context's active document always set *noopener* to true.

5. Let *chosen* be null.
6. Let *targetName* be the empty string.
7. If *name* is not an [ASCII case-insensitive](#) match for "\_blank", then set *targetName* to *name*.
8. If *noopener* is true, then set *chosen* to the result of [creating a new top-level traversable](#)<sup>p991</sup> given null, *targetName*, and *currentNavigable*.
9. Otherwise:
  1. Set *chosen* to the result of [creating a new top-level traversable](#)<sup>p991</sup> given *currentNavigable*'s [active browsing context](#)<sup>p989</sup>, *targetName*, and *currentNavigable*.
  2. If *sandboxingFlagSet*'s [sandboxed navigation browsing context flag](#)<sup>p914</sup> is set, then set *chosen*'s [active browsing context](#)<sup>p989</sup>'s [one permitted sandboxed navigator](#)<sup>p914</sup> to *currentNavigable*'s [active browsing context](#)<sup>p989</sup>.
10. If *sandboxingFlagSet*'s [sandbox propagates to auxiliary browsing contexts flag](#)<sup>p915</sup> is set, then all the flags that are set in *sandboxingFlagSet* must be set in *chosen*'s [active browsing context](#)<sup>p989</sup>'s [popup sandboxing flag set](#)<sup>p917</sup>.

#### Note

If the newly created [navigable](#)<sup>p989</sup> *chosen* is immediately [navigated](#)<sup>p1014</sup>, then the navigation will be done as a "replace"<sup>p1014</sup> navigation.

↪ If the user agent has been configured such that in this instance it will choose *currentNavigable*

Set *chosen* to *currentNavigable*.

↪ If the user agent has been configured such that in this instance it will not find a navigable

Do nothing.

#### Note

User agents are encouraged to provide a way for users to configure the user agent to always choose *currentNavigable*.

9. Return *chosen* and *windowType*.

### 7.3.2 Browsing contexts <sup>p99</sup><sub>8</sub>

A **browsing context** is a programmatic representation of a series of documents, multiple of which can live within a single [navigable](#)<sup>p989</sup>. Each [browsing context](#)<sup>p998</sup> has a corresponding [WindowProxy](#)<sup>p934</sup> object, as well as the following:

- An **opener browsing context**, a [browsing context](#)<sup>p998</sup> or null, initially null.
- An **opener origin at creation**, an [origin](#)<sup>p898</sup> or null, initially null.
- An **is popup** boolean, initially false.

#### Note

The only mandatory impact in this specification of [is popup](#)<sup>p998</sup> is on the [visible](#)<sup>p932</sup> getter of the relevant [BarProp](#)<sup>p932</sup> objects. However, user agents might also use it for [user interface considerations](#)<sup>p1069</sup>.

- An **is auxiliary** boolean, initially false.
- An **initial URL**, a [URL](#) or null, initially null.
- A **virtual browsing context group ID** integer, initially 0. This is used by [opener policy reporting](#)<sup>p904</sup>, to keep track of the browsing context group switches that would have happened if the report-only policy had been enforced.

A [browsing context](#)<sup>p998</sup>'s **active window** is its [WindowProxy](#)<sup>p934</sup> object's [\[\[Window\]\]](#)<sup>p934</sup> internal slot value. A [browsing context](#)<sup>p998</sup>'s **active document** is its [active window](#)<sup>p998</sup>'s [associated Document](#)<sup>p923</sup>.

A [browsing context](#)<sup>p998</sup>'s **top-level traversable** is its [active document](#)<sup>p998</sup>'s [node navigable](#)<sup>p989</sup>'s [top-level traversable](#)<sup>p990</sup>.

A [browsing context](#)<sup>p998</sup> whose [is auxiliary](#)<sup>p998</sup> is true is known as an **auxiliary browsing context**. Auxiliary browsing contexts are always [top-level browsing contexts](#)<sup>p1001</sup>.

It's unclear whether a separate [is auxiliary](#)<sup>p998</sup> concept is necessary. In [issue #5680](#), it is indicated that we may be able to simplify this by using whether or not the [opener browsing context](#)<sup>p998</sup> is null.

**Warning!**

*Modern specifications should avoid using the [browsing context](#)<sup>p998</sup> concept in most cases, unless they are dealing with the subtleties of [browsing context group switches](#)<sup>p905</sup> and [agent cluster allocation](#)<sup>p1002</sup>. Instead, the [Document](#)<sup>p130</sup> and [navigable](#)<sup>p989</sup> concepts are usually more appropriate.*

A **Document's browsing context** is a [browsing context](#)<sup>p998</sup> or null, initially null.

**Note**

A [Document](#)<sup>p130</sup> does not necessarily have a non-null [browsing context](#)<sup>p998</sup>. In particular, data mining tools are likely to never instantiate browsing contexts. A [Document](#)<sup>p130</sup> created using an API such as [createDocument\(\)](#) never has a non-null [browsing context](#)<sup>p998</sup>. And the [Document](#)<sup>p130</sup> originally created for an [iframe](#)<sup>p390</sup> element, which has since been [removed from the document](#)<sup>p46</sup>, has no associated browsing context, since that browsing context was [nulled out](#)<sup>p1066</sup>.

**Note**

In general, there is a 1-to-1 mapping from the [Window](#)<sup>p922</sup> object to the [Document](#)<sup>p130</sup> object, as long as the [Document](#)<sup>p130</sup> object has a non-null [browsing context](#)<sup>p998</sup>. There is one exception. A [Window](#)<sup>p922</sup> can be reused for the presentation of a second [Document](#)<sup>p130</sup> in the same [browsing context](#)<sup>p998</sup>, such that the mapping is then 1-to-2. This occurs when a [browsing context](#)<sup>p998</sup> is [navigated](#)<sup>p1014</sup> from the [initial about:blank](#)<sup>p131</sup> [Document](#)<sup>p130</sup> to another, which will be done with [replacement](#)<sup>p1014</sup>.

### 7.3.2.1 Creating browsing contexts <sup>p99</sup><sub>9</sub>

To **create a new browsing context and document**, given null or a [Document](#)<sup>p130</sup> object *creator*, null or an element *embedder*, and a [browsing context group](#)<sup>p1002</sup> *group*:

1. Let *browsingContext* be a new [browsing context](#)<sup>p998</sup>.
2. Let *unsafeContextCreationTime* be the [unsafe shared current time](#).
3. Let *creatorOrigin* be null.
4. Let *creatorBaseURL* be null.
5. If *creator* is non-null, then:
  1. Set *creatorOrigin* to *creator*'s [origin](#).
  2. Set *creatorBaseURL* to *creator*'s [document base URL](#)<sup>p96</sup>.
  3. Set *browsingContext*'s [virtual browsing context group ID](#)<sup>p998</sup> to *creator*'s [browsing context](#)<sup>p998</sup>'s [top-level browsing context](#)<sup>p1001</sup>'s [virtual browsing context group ID](#)<sup>p998</sup>.
6. Let *sandboxFlags* be the result of [determining the creation sandboxing flags](#)<sup>p917</sup> given *browsingContext* and *embedder*.
7. Let *origin* be the result of [determining the origin](#)<sup>p1001</sup> given [about:blank](#)<sup>p53</sup>, *sandboxFlags*, and *creatorOrigin*.
8. Let *permissionsPolicy* be the result of [creating a permissions policy](#) given *embedder* and *origin*. [\[PERMISSIONSPOLICY\]](#)<sup>p1480</sup>
9. Let *agent* be the result of [obtaining a similar-origin window agent](#)<sup>p1073</sup> given *origin*, *group*, and false.
10. Let *realm execution context* be the result of [creating a new realm](#)<sup>p1077</sup> given *agent* and the following customizations:
  - For the global object, create a new [Window](#)<sup>p922</sup> object.
  - For the global **this** binding, use *browsingContext*'s [WindowProxy](#)<sup>p934</sup> object.

11. Let *topLevelCreationURL* be [about:blank](#)<sup>p53</sup> if *embedder* is null; otherwise *embedder*'s [relevant settings object](#)<sup>p1083</sup>'s [top-level creation URL](#)<sup>p1075</sup>.
12. Let *topLevelOrigin* be *origin* if *embedder* is null; otherwise *embedder*'s [relevant settings object](#)<sup>p1083</sup>'s [top-level origin](#)<sup>p1076</sup>.
13. [Set up a window environment settings object](#)<sup>p933</sup> with [about:blank](#)<sup>p53</sup>, *realm* execution context, null, *topLevelCreationURL*, and *topLevelOrigin*.
14. Let *loadTimingInfo* be a new [document load timing info](#)<sup>p134</sup> with its [navigation start time](#)<sup>p134</sup> set to the result of calling [coarsen time](#) with *unsafeContextCreationTime* and the new [environment settings object](#)<sup>p1076</sup>'s [cross-origin isolated capability](#)<sup>p1076</sup>.
15. Let *document* be a new [Document](#)<sup>p130</sup>, with:

**type**

"html"

**content type**

"text/html"<sup>p1444</sup>

**mode**

"quirks"

**origin**

*origin*

**browsing context**<sup>p999</sup>

*browsingContext*

**permissions policy**<sup>p131</sup>

*permissionsPolicy*

**active sandboxing flag set**<sup>p917</sup>

*sandboxFlags*

**load timing info**<sup>p134</sup>

*loadTimingInfo*

**is initial** [about:blank](#)<sup>p131</sup>

true

**about base URL**<sup>p131</sup>

*creatorBaseURL*

**allow declarative shadow roots**

true

16. If *creator* is non-null, then:
  1. Set *document*'s [referrer](#)<sup>p130</sup> to the [serialization](#) of *creator*'s [URL](#).
  2. Set *document*'s [policy container](#)<sup>p131</sup> to a [clone](#)<sup>p917</sup> of *creator*'s [policy container](#)<sup>p131</sup>.
  3. If *creator*'s [origin](#) is [same origin](#)<sup>p899</sup> with *creator*'s [relevant settings object](#)<sup>p1083</sup>'s [top-level origin](#)<sup>p1076</sup>, then set *document*'s [opener policy](#)<sup>p131</sup> to *creator*'s [browsing context](#)<sup>p999</sup>'s [top-level browsing context](#)<sup>p1001</sup>'s [active document](#)<sup>p998</sup>'s [opener policy](#)<sup>p131</sup>.
17. **Assert**: *document*'s [URL](#) and *document*'s [relevant settings object](#)<sup>p1083</sup>'s [creation URL](#)<sup>p1075</sup> are [about:blank](#)<sup>p53</sup>.
18. Mark *document* as [ready for post-load tasks](#)<sup>p1359</sup>.
19. [Populate with html/head/body](#)<sup>p1059</sup> given *document*.
20. [Make active](#)<sup>p1051</sup> *document*.
21. [Completely finish loading](#)<sup>p1063</sup> *document*.
22. Return *browsingContext* and *document*.

**To create a new top-level browsing context and document:**

1. Let *group* and *document* be the result of [creating a new browsing context group and document](#)<sup>p1003</sup>.
2. Return *group*'s [browsing context set](#)<sup>p1002</sup>[0] and *document*.

**To create a new auxiliary browsing context and document**, given a [browsing context](#)<sup>p998</sup> *opener*:

1. Let *openerTopLevelBrowsingContext* be *opener*'s [top-level traversable](#)<sup>p998</sup>'s [active browsing context](#)<sup>p989</sup>.

2. Let *group* be *openerTopLevelBrowsingContext*'s [group](#)<sup>p1002</sup>.
3. **Assert:** *group* is non-null, as [navigating](#)<sup>p1014</sup> invokes this directly.
4. Let *browsingContext* and *document* be the result of [creating a new browsing context and document](#)<sup>p999</sup> with *opener*'s [active document](#)<sup>p989</sup>, null, and *group*.
5. Set *browsingContext*'s [is auxiliary](#)<sup>p998</sup> to true.
6. **Append**<sup>p1003</sup> *browsingContext* to *group*.
7. Set *browsingContext*'s [opener browsing context](#)<sup>p998</sup> to *opener*.
8. Set *browsingContext*'s [virtual browsing context group ID](#)<sup>p998</sup> to *openerTopLevelBrowsingContext*'s [virtual browsing context group ID](#)<sup>p998</sup>.
9. Set *browsingContext*'s [opener origin at creation](#)<sup>p998</sup> to *opener*'s [active document](#)<sup>p989</sup>'s [origin](#).
10. Return *browsingContext* and *document*.

To **determine the origin**, given a [URL](#) *url*, a [sandboxing flag set](#)<sup>p914</sup> *sandboxFlags*, and an [origin](#)<sup>p898</sup>-or-null *sourceOrigin*:

1. If *sandboxFlags* has its [sandboxed origin browsing context flag](#)<sup>p915</sup> set, then return a new [opaque origin](#)<sup>p898</sup>.
2. If *url* is null, then return a new [opaque origin](#)<sup>p898</sup>.
3. If *url* is [about:srcdoc](#)<sup>p96</sup>, then:
  1. **Assert:** *sourceOrigin* is non-null.
  2. Return *sourceOrigin*.
4. If *url* [matches about:blank](#)<sup>p96</sup> and *sourceOrigin* is non-null, then return *sourceOrigin*.
5. Return *url*'s [origin](#).

**Note**  
The cases that return *sourceOrigin* result in two [Document](#)<sup>p130</sup>s that end up with the same underlying [origin](#), meaning that [document.domain](#)<sup>p901</sup> affects both.

### 7.3.2.2 Related browsing contexts <sup>§ p1001</sup>

A [browsing context](#)<sup>p998</sup> *potentialDescendant* is said to be an **ancestor** of a browsing context *potentialAncestor* if the following algorithm returns true:

1. Let *potentialDescendantDocument* be *potentialDescendant*'s [active document](#)<sup>p998</sup>.
2. If *potentialDescendantDocument* is not [fully active](#)<sup>p1003</sup>, then return false.
3. Let *ancestorBCs* be the list obtained by taking the [browsing context](#)<sup>p999</sup> of the [active document](#)<sup>p989</sup> of each member of *potentialDescendantDocument*'s [ancestor navigables](#)<sup>p994</sup>.
4. If *ancestorBCs* [contains](#) *potentialAncestor*, then return true.
5. Return false.

A **top-level browsing context** is a [browsing context](#)<sup>p998</sup> whose [active document](#)<sup>p998</sup>'s [node navigable](#)<sup>p989</sup> is a [traversable navigable](#)<sup>p990</sup>.

**Note**  
It is not required to be a [top-level traversable](#)<sup>p990</sup>.

The **top-level browsing context** of a [browsing context](#)<sup>p998</sup> *start* is the result of the following algorithm:

1. If *start*'s [active document](#)<sup>p998</sup> is not [fully active](#)<sup>p1003</sup>, then return null.

2. Let *navigable* be *start*'s [active document](#)<sup>p998</sup>'s [node navigable](#)<sup>p989</sup>.
3. While *navigable*'s [parent](#)<sup>p989</sup> is not null, set *navigable* to *navigable*'s [parent](#)<sup>p989</sup>.
4. Return *navigable*'s [active browsing context](#)<sup>p989</sup>.

#### ⚠Warning!

*The terms [ancestor browsing context](#)<sup>p1001</sup> and [top-level browsing context](#)<sup>p1001</sup> are rarely useful, since [browsing contexts](#)<sup>p998</sup> in general are usually the inappropriate specification concept to use<sup>p999</sup>. Note in particular that when a [browsing context](#)<sup>p998</sup>'s [active document](#)<sup>p998</sup> is not fully active<sup>p1003</sup>, it never counts as an ancestor or top-level browsing context, and as such these concepts are not useful when [bfcache](#)<sup>p1006</sup> is in play.*

*Instead, use concepts such as the [ancestor navigables](#)<sup>p994</sup> collection, the [parent navigable](#)<sup>p989</sup>, or a [navigable's top-level traversable](#)<sup>p990</sup>.*

A [browsing context](#)<sup>p998</sup> *A* is **familiar with** a second [browsing context](#)<sup>p998</sup> *B* if the following algorithm returns true:

1. If *A*'s [active document](#)<sup>p998</sup>'s [origin](#) is [same origin](#)<sup>p899</sup> with *B*'s [active document](#)<sup>p998</sup>'s [origin](#), then return true.
2. If *A*'s [top-level browsing context](#)<sup>p1001</sup> is *B*, then return true.
3. If *B* is an [auxiliary browsing context](#)<sup>p999</sup> and *A* is [familiar with](#)<sup>p1002</sup> *B*'s [opener browsing context](#)<sup>p998</sup>, then return true.
4. If there exists an [ancestor browsing context](#)<sup>p1001</sup> of *B* whose [active document](#)<sup>p998</sup> has the [same](#)<sup>p899</sup> [origin](#) as the [active document](#)<sup>p998</sup> of *A*, then return true.

#### Note

*This includes the case where *A* is an [ancestor browsing context](#)<sup>p1001</sup> of *B*.*

5. Return false.

### 7.3.2.3 Groupings of browsing contexts <sup>p1002</sup>

A [top-level browsing context](#)<sup>p1001</sup> has an associated **group** (null or a [browsing context group](#)<sup>p1002</sup>). It is initially null.

A user agent holds a **browsing context group set** (a [set](#) of [browsing context groups](#)<sup>p1002</sup>).

A **browsing context group** holds a **browsing context set** (a [set](#) of [top-level browsing contexts](#)<sup>p1001</sup>).

#### Note

*A [top-level browsing context](#)<sup>p1001</sup> is added to the [group](#)<sup>p1002</sup> when the group is [created](#)<sup>p1003</sup>. All subsequent [top-level browsing contexts](#)<sup>p1001</sup> added to the [group](#)<sup>p1002</sup> will be [auxiliary browsing contexts](#)<sup>p999</sup>.*

A [browsing context group](#)<sup>p1002</sup> has an associated **agent cluster map** (a weak [map](#) of [agent cluster keys](#)<sup>p1073</sup> to [agent clusters](#)). User agents are responsible for collecting agent clusters when it is deemed that nothing can access them anymore.

A [browsing context group](#)<sup>p1002</sup> has an associated **historical agent cluster key map**, which is a [map](#) of [origins](#)<sup>p898</sup> to [agent cluster keys](#)<sup>p1073</sup>. This map is used to ensure the consistency of the [origin-keyed agent clusters](#)<sup>p902</sup> feature by recording what agent cluster keys were previously used for a given origin.

#### Note

*The [historical agent cluster key map](#)<sup>p1002</sup> only ever gains entries over the lifetime of the browsing context group.*

A [browsing context group](#)<sup>p1002</sup> has a **cross-origin isolation mode**, which is a [cross-origin isolation mode](#)<sup>p1002</sup>. It is initially ["none"](#)<sup>p1002</sup>.

A **cross-origin isolation mode** is one of three possible values: ["none"](#), ["logical"](#), or ["concrete"](#).

#### Note

"[logical](#)<sup>p1002</sup>" and "[concrete](#)<sup>p1002</sup>" are similar. They are both used for [browsing context groups](#)<sup>p1002</sup> where:

- every top-level [Document](#)<sup>p130</sup> has `[Cross-Origin-Opener-Policy](#)<sup>p904</sup>: [same-origin](#)<sup>p903</sup>`, and
- every [Document](#)<sup>p130</sup> has a `[Cross-Origin-Embedder-Policy](#)<sup>p913</sup>` header whose value is [compatible with cross-origin isolation](#)<sup>p912</sup>.

On some platforms, it is difficult to provide the security properties required to grant safe access to the APIs gated by the [cross-origin isolated capability](#)<sup>p1076</sup>. As a result, only "[concrete](#)<sup>p1002</sup>" can grant access that capability. "[logical](#)<sup>p1002</sup>" is used on platform not supporting this capability, where various restrictions imposed by cross-origin isolation will still apply, but the capability is not granted.

To create a new browsing context group and document:

1. Let *group* be a new [browsing context group](#)<sup>p1002</sup>.
2. [Append](#) *group* to the user agent's [browsing context group set](#)<sup>p1002</sup>.
3. Let *browsingContext* and *document* be the result of [creating a new browsing context and document](#)<sup>p999</sup> with null, null, and *group*.
4. [Append](#)<sup>p1003</sup> *browsingContext* to *group*.
5. Return *group* and *document*.

To **append** a [top-level browsing context](#)<sup>p1001</sup> *browsingContext* to a [browsing context group](#)<sup>p1002</sup> *group*:

1. [Append](#) *browsingContext* to *group*'s [browsing context set](#)<sup>p1002</sup>.
2. Set *browsingContext*'s [group](#)<sup>p1002</sup> to *group*.

To **remove** a [top-level browsing context](#)<sup>p1001</sup> *browsingContext*:

1. [Assert](#): *browsingContext*'s [group](#)<sup>p1002</sup> is non-null.
2. Let *group* be *browsingContext*'s [group](#)<sup>p1002</sup>.
3. Set *browsingContext*'s [group](#)<sup>p1002</sup> to null.
4. [Remove](#) *browsingContext* from *group*'s [browsing context set](#)<sup>p1002</sup>.
5. If *group*'s [browsing context set](#)<sup>p1002</sup> is empty, then [remove](#) *group* from the user agent's [browsing context group set](#)<sup>p1002</sup>.

#### Note

[Append](#)<sup>p1003</sup> and [remove](#)<sup>p1003</sup> are primitive operations that help define the lifetime of a [browsing context group](#)<sup>p1002</sup>. They are called by higher-level creation and destruction operations for [Document](#)<sup>p130</sup>s and [browsing contexts](#)<sup>p998</sup>.

When there are no [Document](#)<sup>p130</sup> objects whose [browsing context](#)<sup>p999</sup> equals a given [browsing context](#)<sup>p998</sup> (i.e., all such [Document](#)<sup>p130</sup>s have been [destroyed](#)<sup>p1066</sup>), and that [browsing context](#)<sup>p998</sup>'s [WindowProxy](#)<sup>p934</sup> is eligible for garbage collection, then the [browsing context](#)<sup>p998</sup> will never be accessed again. If it is a [top-level browsing context](#)<sup>p1001</sup>, then at this point the user agent must [remove](#)<sup>p1003</sup> it.

### 7.3.3 Fully active documents §<sup>p1003</sup>

A [Document](#)<sup>p130</sup> *d* is said to be **fully active** when *d* is the [active document](#)<sup>p989</sup> of a [navigable](#)<sup>p989</sup> *navigable*, and either *navigable* is a [top-level traversable](#)<sup>p990</sup> or *navigable*'s [container document](#)<sup>p992</sup> is [fully active](#)<sup>p1003</sup>.

Because they are associated with an element, [child navigables](#)<sup>p992</sup> are always tied to a specific [Document](#)<sup>p130</sup>, their [container document](#)<sup>p992</sup>, in their [parent navigable](#)<sup>p989</sup>. User agents must not allow the user to interact with [child navigables](#)<sup>p992</sup> whose [container documents](#)<sup>p992</sup> are not themselves [fully active](#)<sup>p1003</sup>.

#### Example

The following example illustrates how a [Document](#)<sup>p130</sup> can be the [active document](#)<sup>p989</sup> of its [node navigable](#)<sup>p989</sup>, while not being [fully active](#)<sup>p1003</sup>. Here a.html is loaded into a browser window, b-1.html starts out loaded into an [iframe](#)<sup>p390</sup> as shown, and b-2.html and c.html are omitted (they can simply be an empty document).

```
<!-- a.html -->
<!DOCTYPE html>
<html lang="en">
<title>Navigable A</title>

<iframe src="b-1.html"></iframe>
<button onclick="frames[0].location.href = 'b-2.html'">Click me</button>

<!-- b-1.html -->
<!DOCTYPE html>
<html lang="en">
<title>Navigable B</title>

<iframe src="c.html"></iframe>
```

At this point, the documents given by a.html, b-1.html, and c.html are all the [active documents](#)<sup>p989</sup> of their respective [node navigables](#)<sup>p989</sup>. They are also all [fully active](#)<sup>p1003</sup>.

After clicking on the [button](#)<sup>p566</sup>, and thus loading a new [Document](#)<sup>p130</sup> from b-2.html into navigable B, we have the following results:

- The a.html [Document](#)<sup>p130</sup> remains both the [active document](#)<sup>p989</sup> of navigable A, and [fully active](#)<sup>p1003</sup>.
- The b-1.html [Document](#)<sup>p130</sup> is now *not* the [active document](#)<sup>p989</sup> of navigable B. As such it is also not [fully active](#)<sup>p1003</sup>.
- The new b-2.html [Document](#)<sup>p130</sup> is now the [active document](#)<sup>p989</sup> of navigable B, and is also [fully active](#)<sup>p1003</sup>.
- The c.html [Document](#)<sup>p130</sup> is still the [active document](#)<sup>p989</sup> of navigable C. However, since C's [container document](#)<sup>p992</sup> is the b-1.html [Document](#)<sup>p130</sup>, which is itself not [fully active](#)<sup>p1003</sup>, this means the c.html [Document](#)<sup>p130</sup> is now not [fully active](#)<sup>p1003</sup>.

## 7.4 Navigation and session history §<sup>p10</sup><sub>04</sub>

Welcome to the dragon's maw. Navigation, session history, and the traversal through that session history are some of the most complex parts of this standard.

The basic concept may not seem so difficult:

- The user is looking at a [navigable](#)<sup>p989</sup> that is presenting its [active document](#)<sup>p989</sup>. They [navigate](#)<sup>p1014</sup> it to another [URL](#).
- The browser fetches the given URL from the network, using it to [populate](#)<sup>p1029</sup> a new [session history entry](#)<sup>p1005</sup> with a newly-[created](#)<sup>p1056</sup> [Document](#)<sup>p130</sup>.
- The browser updates the [navigable](#)<sup>p989</sup>'s [active session history entry](#)<sup>p989</sup> to the newly-populated one, and thus updates the [active document](#)<sup>p989</sup> that it is showing to the user.
- At some point later, the user [presses the browser back button](#)<sup>p1028</sup> to go back to the previous [session history entry](#)<sup>p1005</sup>.
- The browser looks at the [URL](#)<sup>p1005</sup> stored in that [session history entry](#)<sup>p1005</sup>, and uses it to re-fetch and [populate](#)<sup>p1029</sup> that entry's [document](#)<sup>p1005</sup>.
- The browser again updates the [navigable](#)<sup>p989</sup>'s [active session history entry](#)<sup>p989</sup>.

You can see some of the intertwined complexity peeking through here, in how traversal can cause a navigation (i.e., a network fetch to a stored URL), and how a navigation necessarily needs to interface with the session history list to ensure that when it finishes the user is looking at the right thing. But the real problems come in with the various edge cases and interacting web platform features:

- [Child navigables](#)<sup>p992</sup> (e.g., those contained in [iframe](#)<sup>p390</sup>s) can also navigate and traverse, but those navigations need to be linearized into [a single session history list](#)<sup>p990</sup> since the user only has a single back/forward interface for the entire [traversable navigable](#)<sup>p990</sup> (e.g., browser tab).
- Since the user can traverse back more than a single step in the session history (e.g., by holding down their back button), they can end up traversing multiple [navigables](#)<sup>p989</sup> at the same time when [child navigables](#)<sup>p992</sup> are involved. This needs to be synchronized across all of the involved navigables, which might involve multiple [event loops](#)<sup>p1123</sup> or even [agent clusters](#).
- During navigation, servers can respond with 204 or 205 status codes or with ``Content-Disposition: attachment`` headers, which cause navigation to abort and the [navigable](#)<sup>p989</sup> to stay on its original [active document](#)<sup>p998</sup>. (This is much worse if it happens during a traversal-initiated navigation!)
- Various other HTTP headers, such as ``Location``, ``Refresh``<sup>p1069</sup>, ``X-Frame-Options``<sup>p1068</sup>, and those for Content Security Policy, contribute to either the [fetching process](#)<sup>p1033</sup>, or the [Document-creation process](#)<sup>p1056</sup>, or both. The ``Cross-Origin-Opener-Policy``<sup>p904</sup> header even contributes to the [browsing context selection and creation](#)<sup>p905</sup> process!
- Some navigations (namely [fragment navigations](#)<sup>p1021</sup> and [single-page app navigations](#)<sup>p1028</sup>) are synchronous, meaning that JavaScript code expects to observe the navigation's results instantly. This then needs to be synchronized with the view of the session history that all other [navigables](#)<sup>p989</sup> in the tree see, which can be subject to race conditions and necessitate resolving conflicting views of the session history.
- The platform has accumulated various exciting navigation-related features that need special-casing, such as [javascript:](#)<sup>p1019</sup> URLs, [srcdoc](#)<sup>p391</sup> [iframe](#)<sup>p390</sup>s, and the [beforeunload](#)<sup>p1471</sup> event.

In what follows, we have attempted to guide the reader through these complexities by appropriately cordoning them off into labeled sections and algorithms, and giving appropriate words of introduction where possible. Nevertheless, if you wish to truly understand navigation and session history, [the usual advice](#)<sup>p30</sup> will be invaluable.

## 7.4.1 Session history <sup>p1005</sup>

### 7.4.1.1 Session history entries <sup>p1005</sup>

A **session history entry** is a [struct](#) with the following [items](#):

- **step**, a non-negative integer or "pending", initially "pending".
- **URL**, a [URL](#).
- **document state**, a [document state](#)<sup>p1006</sup>.
- **classic history API state**, which is [serialized state](#)<sup>p1006</sup>, initially [StructuredSerializeForStorage](#)<sup>p122</sup>(null).
- **navigation API state**, which is a [serialized state](#)<sup>p1006</sup>, initially [StructuredSerializeForStorage](#)<sup>p122</sup>(undefined).
- **navigation API key**, which is a string, initially set to the result of [generating a random UUID](#).
- **navigation API ID**, which is a string, initially set to the result of [generating a random UUID](#).
- **scroll restoration mode**, a [scroll restoration mode](#)<sup>p1006</sup>, initially `"auto"`<sup>p1006</sup>.
- **scroll position data**, which is scroll position data for the [document](#)<sup>p1005</sup>'s [restorable scrollable regions](#)<sup>p1055</sup>.
- **persisted user state**, which is [implementation-defined](#), initially null

#### Example

For example, some user agents might want to persist the values of form controls.

#### Note

*User agents that persist the value of form controls are encouraged to also persist their directionality (the value of the element's `dir`<sup>p160</sup> attribute). This prevents values from being displayed incorrectly after a history traversal when the user had originally entered the values with an explicit, non-default directionality.*

To get a [session history entry](#)<sup>p1005</sup>'s **document**, return its [document state](#)<sup>p1005</sup>'s [document](#)<sup>p1006</sup>.

**Serialized state** is a serialization (via [StructuredSerializeForStorage](#)<sup>p122</sup>) of an object representing a user interface state. We sometimes informally refer to "state objects", which are the objects representing user interface state supplied by the author, or alternately the objects created by deserializing (via [StructuredDeserialize](#)<sup>p122</sup>) serialized state.

Pages can [add](#)<sup>p946</sup> [serialized state](#)<sup>p1006</sup> to the session history. These are then [deserialized](#)<sup>p122</sup> and [returned to the script](#)<sup>p1472</sup> when the user (or script) goes back in the history, thus enabling authors to use the "navigation" metaphor even in one-page applications.

#### Note

*[Serialized state](#)<sup>p1006</sup> is intended to be used for two main purposes: first, storing a prepared description of the state in the [URL](#) so that in the simple case an author doesn't have to do the parsing (though one would still need the parsing for handling [URLs](#) passed around by users, so it's only a minor optimization). Second, so that the author can store state that one wouldn't store in the [URL](#) because it only applies to the current [Document](#)<sup>p130</sup> instance and it would have to be reconstructed if a new [Document](#)<sup>p130</sup> were opened.*

*An example of the latter would be something like keeping track of the precise coordinate from which a popup [div](#)<sup>p256</sup> was made to animate, so that if the user goes back, it can be made to animate to the same location. Or alternatively, it could be used to keep a pointer into a cache of data that would be fetched from the server based on the information in the [URL](#), so that when going back and forward, the information doesn't have to be fetched again.*

A **scroll restoration mode** indicates whether the user agent should restore the persisted scroll position (if any) when traversing to an [entry](#)<sup>p1005</sup>. A scroll restoration mode is one of the following:

#### "auto"

The user agent is responsible for restoring the scroll position upon navigation.

#### "manual"

The page is responsible for restoring the scroll position and the user agent does not attempt to do so automatically

### 7.4.1.2 Document state § <sup>p10</sup><sub>06</sub>

**Document state** holds state inside a [session history entry](#)<sup>p1005</sup> regarding how to present and, if necessary, recreate, a [Document](#)<sup>p130</sup>. It has:

- A **document**, a [Document](#)<sup>p130</sup> or null, initially null.

#### Note

*When a history entry is [active](#)<sup>p989</sup>, it has a [Document](#)<sup>p130</sup> in its [document state](#)<sup>p1005</sup>. However, when a [Document](#)<sup>p130</sup> is not [fully active](#)<sup>p1003</sup>, it's possible for it to be [destroyed](#)<sup>p1066</sup> to free resources. In such cases, this [document](#)<sup>p1006</sup> item will be nulled out. The [URL](#)<sup>p1005</sup> and other data in the [session history entry](#)<sup>p1005</sup> and [document state](#)<sup>p1005</sup> is then used to bring a new [Document](#)<sup>p130</sup> into being to take the place of the original, in the case where the user agent finds itself having to traverse to the entry.*

*If the [Document](#)<sup>p130</sup> is not [destroyed](#)<sup>p1066</sup>, then during [history traversal](#)<sup>p1028</sup>, it can be [reactivated](#)<sup>p1051</sup>. The cache in which browsers store such [Document](#)<sup>p130</sup>s is often called a back-forward cache, or bfcache (or perhaps "[blazingly fast](#)" cache).*

- A **history policy container**, a [policy container](#)<sup>p917</sup> or null, initially null.
- A **request referrer**, which is "no-referrer", "client", or a [URL](#), initially "client".
- A **request referrer policy**, which is a [referrer policy](#), initially the [default referrer policy](#).

#### Note

*The [request referrer policy](#)<sup>p1006</sup> is distinct from the [history policy container](#)<sup>p1006</sup>'s [referrer policy](#)<sup>p917</sup>. The former is used for fetches of this document, whereas the latter controls fetches by this document.*

- An **initiator origin**, which is an [origin](#)<sup>p898</sup> or null, initially null.
- An **origin**, which is an [origin](#)<sup>p898</sup> or null, initially null.

#### Note

This is the origin that we set "about:"-schemed [Document<sup>p130</sup>](#)'s [origin](#) to. We store it here because it is also used when restoring these [Document<sup>p130</sup>](#)s during traversal, since they are reconstructed locally without visiting the network. It is also used to compare the origin before and after the [session history entry<sup>p1005</sup>](#) is [repopulated<sup>p1029</sup>](#). If the origins change, the [navigable target name<sup>p1007</sup>](#) is cleared.

- An **about base URL**, which is a [URL](#) or null, initially null.

#### Note

This will be populated only for "about:"-schemed [Document<sup>p130</sup>](#)s and will be the [fallback base URL<sup>p96</sup>](#) for those [Document<sup>p130</sup>](#)s. It is a snapshot of the initiator [Document<sup>p130</sup>](#)'s [document base URL<sup>p96</sup>](#).

- **Nested histories**, a [list](#) of [nested histories<sup>p1007</sup>](#), initially an empty [list](#).
- A **resource**, a string, [POST resource<sup>p1007</sup>](#) or null, initially null.

#### Note

A string is treated as HTML. It's used to store the source of an [iframe srcdoc document<sup>p391</sup>](#).

- A **reload pending** boolean, initially false.
- An **ever populated** boolean, initially false.
- A **navigable target name** string, initially the empty string.
- A **not restored reasons**, a [not restored reasons<sup>p988</sup>](#) or null, initially null.

User agents may [destroy a document and its descendants<sup>p1066</sup>](#) given the [documents<sup>p1006</sup>](#) of [document states<sup>p1006</sup>](#) with non-null [documents<sup>p1006</sup>](#), as long as the [Document<sup>p130</sup>](#) is not [fully active<sup>p1003</sup>](#).

Apart from that restriction, this standard does not specify when user agents should destroy the [document<sup>p1006</sup>](#) stored in a [document state<sup>p1006</sup>](#), versus keeping it cached.

A **POST resource** has:

- A **request body**, a [byte sequence](#) or failure.

This is only ever accessed [in parallel<sup>p43</sup>](#), so it doesn't need to be stored in memory. However, it must return the same [byte sequence](#) each time. If this isn't possible due to resources changing on disk, or if resources can no longer be accessed, then this must be set to failure.

- A **request content-type**, which is `application/x-www-form-urlencoded`, `multipart/form-datap1474`, or `text/plain`.

A **nested history** has:

- An **id**, a [unique internal value<sup>p96</sup>](#).

#### Note

This is used to associate the [nested history<sup>p1007</sup>](#) with a [navigable<sup>p989</sup>](#).

- **Entries**, a [list](#) of [session history entries<sup>p1005</sup>](#).

This will later contain ways to identify a child navigable across reloads.

Several contiguous entries in a session history can share the same [document state<sup>p1005</sup>](#). This can occur when the initial entry is reached via normal [navigation<sup>p1014</sup>](#), and the following entry is added via [history.pushState\(\)<sup>p946</sup>](#). Or it can occur via [navigation to a fragment<sup>p1021</sup>](#).

## Note

All entries that share the same [document state](#)<sup>p1005</sup> (and that are therefore merely different states of one particular document) are contiguous by construction.

A [Document](#)<sup>p130</sup> has a **latest entry**, a [session history entry](#)<sup>p1005</sup> or null.

## Note

This is the entry that was most recently represented by a given [Document](#)<sup>p130</sup>. A single [Document](#)<sup>p130</sup> can represent many [session history entries](#)<sup>p1005</sup> over time, as many contiguous [session history entries](#)<sup>p1005</sup> can share the same [document state](#)<sup>p1005</sup> as explained above.

### 7.4.1.3 Centralized modifications of session history <sup>p1008</sup>

To maintain a single source of truth, all modifications to a [traversable navigable](#)<sup>p990</sup>'s [session history entries](#)<sup>p990</sup> need to be synchronized. This is especially important due to how session history is influenced by all of the descendant [navigables](#)<sup>p989</sup>, and thus by multiple [event loops](#)<sup>p1123</sup>. To accomplish this, we use the [session history traversal parallel queue](#)<sup>p1008</sup> structure.

A **session history traversal parallel queue** is very similar to a [parallel queue](#)<sup>p43</sup>. It has an **algorithm set**, an **ordered set**.

The **items** in a [session history traversal parallel queue](#)<sup>p1008</sup>'s [algorithm set](#)<sup>p1008</sup> are either algorithm steps, or **synchronous navigation steps**, which are a particular brand of algorithm steps involving a **target navigable** (a [navigable](#)<sup>p989</sup>).

To **append session history traversal steps** to a [traversable navigable](#)<sup>p990</sup> traversable given algorithm steps *steps*, **append** steps to traversable's [session history traversal queue](#)<sup>p990</sup>'s [algorithm set](#)<sup>p1008</sup>.

To **append session history synchronous navigation steps** involving a [navigable](#)<sup>p989</sup> *targetNavigable* to a [traversable navigable](#)<sup>p990</sup> traversable given algorithm steps *steps*, **append** steps as [synchronous navigation steps](#)<sup>p1008</sup> targeting [target navigable](#)<sup>p1008</sup> *targetNavigable* to traversable's [session history traversal queue](#)<sup>p990</sup>'s [algorithm set](#)<sup>p1008</sup>.

To **start a new session history traversal parallel queue**:

1. Let *sessionHistoryTraversalQueue* be a new [session history traversal parallel queue](#)<sup>p1008</sup>.
2. Run the following steps [in parallel](#)<sup>p43</sup>:
  1. While true:
    1. If *sessionHistoryTraversalQueue*'s [algorithm set](#)<sup>p1008</sup> is empty, then **continue**.
    2. Let *steps* be the result of **dequeuing** from *sessionHistoryTraversalQueue*'s [algorithm set](#)<sup>p1008</sup>.
    3. Run *steps*.
3. Return *sessionHistoryTraversalQueue*.

[Synchronous navigation steps](#)<sup>p1008</sup> are tagged in the [algorithm set](#)<sup>p1008</sup> to allow them to conditionally "jump the queue". This is handled [within apply the history step](#)<sup>p1044</sup>.

## Example

Imagine the joint session history depicted by this [Jake diagram](#)<sup>p993</sup>:

	0	1
top	/a	/b

And the following code runs at the top level:

```
history.back();
location.href = '#foo';
```

The desired result is:

	0	1	2
top	/a	/b	/b#foo

This isn't straightforward, as the sync navigation wins the race in terms of being observable, whereas the traversal wins the race in terms of queuing steps on the [session history traversal parallel queue](#)<sup>p1008</sup>. To achieve this result, the following happens:

1. [history.back\(\)](#)<sup>p946</sup> [appends steps](#)<sup>p1008</sup> intended to traverse by a delta of  $-1$ .
2. [location.href = '#foo'](#)<sup>p939</sup> synchronously changes the [active session history entry](#)<sup>p989</sup> entry to a newly-created one, with the URL `/b#foo`, and [appends synchronous steps](#)<sup>p1008</sup> to notify the central source of truth about that new entry. Note that this does *not* yet update the [current session history entry](#)<sup>p989</sup>, [current session history step](#)<sup>p990</sup>, or the [session history entries](#)<sup>p990</sup> list; those updates cannot be done synchronously, and instead must be done as part of the queued steps.
3. On the [session history traversal parallel queue](#)<sup>p1008</sup>, the steps queued by [history.back\(\)](#)<sup>p946</sup> run:
  1. The target history step is determined to be 0: the [current session history step](#)<sup>p990</sup> (i.e., 1) plus the intended delta of  $-1$ .
  2. We enter the main [apply the history step](#)<sup>p1041</sup> algorithm.

The entry at step 0, for the `/a` URL, has its [document](#)<sup>p1005</sup> [populated](#)<sup>p1029</sup>.

Meanwhile, the queue is checked for [synchronous navigation steps](#)<sup>p1008</sup>. The steps queued by the [location.href](#)<sup>p939</sup> setter now run, and block the traversal from performing effects beyond document population (such as, unloading documents and switching active history entries) until they are finished. Those steps cause the following to happen:

1. The entry with URL `/b#foo` is added, with its [step](#)<sup>p1005</sup> determined to be 2: the [current session history step](#)<sup>p990</sup> (i.e., 1) plus 1.
2. We fully switch to that newly added entry, including a nested call to [apply the history step](#)<sup>p1041</sup>. This ultimately results in [updating the document](#)<sup>p1049</sup> by dispatching events like [hashchange](#)<sup>p1471</sup>.

Only once that is all complete, and the `/a` history entry has been fully populated with a [document](#)<sup>p1005</sup>, do we move on with applying the history step given the target step of 0.

At this point, the [Document](#)<sup>p138</sup> with URL `/b#foo` [unloads](#)<sup>p1064</sup>, and we finish moving to our target history step 0, which makes the entry with URL `/a` become the [active session history entry](#)<sup>p989</sup> and 0 become the [current session history step](#)<sup>p990</sup>.

## Example

Here is another more complex example, involving races between populating two different [iframe](#)<sup>p398</sup>s, and a synchronous navigation once one of those iframes loads. We start with this setup:

	0	1	2
top	/t		
frames[0]	/i-0-a	/i-0-b	
frames[1]	/i-1-a	/i-1-b	

and then call [history.go\(-2\)](#)<sup>p946</sup>. The following then occurs:

1. [history.go\(-2\)](#)<sup>p946</sup> [appends steps](#)<sup>p1008</sup> intended to traverse by a delta of  $-2$ . Once those steps run:
  1. The target step is determined to be  $2 + (-2) = 0$ .
  2. In parallel, the fetches are made to [populate](#)<sup>p1029</sup> the two iframes, fetching `/i-0-a` and `/i-1-a` respectively. Meanwhile, the queue is checked for [synchronous navigation steps](#)<sup>p1008</sup>. There aren't any right now.
  3. In the fetch race, the fetch for `/i-0-a` wins. We proceed onward to finish all of [apply the history step](#)<sup>p1041</sup>'s work

for how the traversal impacts the frames[0] [navigable<sup>p989</sup>](#), including updating its [active session history entry<sup>p989</sup>](#) to the entry with URL /i-0-a.

4. Before the fetch for /i-1-a finishes, we reach the point where [scripts may run for the newly-created document<sup>p1051</sup>](#) in the frames[0] [navigable<sup>p989</sup>](#)'s [active document<sup>p989</sup>](#). Some such script does run:

```
location.href = '#foo'
```

This synchronously changes the frames[0] navigable's [active session history entry<sup>p989</sup>](#) entry to a newly-created one, with the URL /i-0-a#foo, and [appends synchronous steps<sup>p1008</sup>](#) to notify the central source of truth about that new entry.

Unlike in the [previous example<sup>p1008</sup>](#), these synchronous steps do *not* "jump the queue" and update the [traversable<sup>p990</sup>](#) before we finish the fetch for /i-1-a. This is because the navigable in question, frames[0], has already been altered as part of the traversal, so we know that with the [current session history step<sup>p990</sup>](#) being 2, adding the new entry as a step 3 doesn't make sense.

5. Once the fetch for /i-1-a finally finishes, we proceed to finish updating the frames[1] [navigable<sup>p989</sup>](#) for the traversal, including updating its [active session history entry<sup>p989</sup>](#) to the entry with URL /i-1-a.
  6. Now that both navigables have finished processing the traversal, we update the [current session history step<sup>p990</sup>](#) to the target step of 0.
2. Now we can process the steps that were queued for the synchronous navigation:
    1. The /i-0-a#foo entry is added, with its [step<sup>p1005</sup>](#) determined to be 1: the [current session history step<sup>p990</sup>](#) (i.e., 0) plus 1. This also [clears existing forward history<sup>p1011</sup>](#).
    2. We fully switch to that newly added entry, including calling [apply the history step<sup>p1041</sup>](#). This ultimately results in [updating the document<sup>p1049</sup>](#) by dispatching events like [hashchange<sup>p1471</sup>](#), as well as updating the [current session history step<sup>p990</sup>](#) to the target step of 1.

The end result is:

	0	1
top	/t	
frames[0]	/i-0-a	/i-0-a#foo
frames[1]	/i-1-a	

#### 7.4.1.4 Low-level operations on session history §<sup>p10</sup> 10

This section contains a miscellaneous grab-bag of operations that we perform throughout the standard when manipulating session history. The best way to get a sense of what they do is to look at their call sites.

To **get session history entries** of a [navigable<sup>p989</sup>](#) *navigable*:

1. Let *traversable* be *navigable*'s [traversable navigable<sup>p990</sup>](#).
2. **Assert**: this is running within *traversable*'s [session history traversal queue<sup>p990</sup>](#).
3. If *navigable* is *traversable*, return *traversable*'s [session history entries<sup>p990</sup>](#).
4. Let *docStates* be an empty [ordered set](#) of [document states<sup>p1006</sup>](#).
5. For each *entry* of *traversable*'s [session history entries<sup>p990</sup>](#), **append** *entry*'s [document state<sup>p1005</sup>](#) to *docStates*.
6. **For each** *docState* of *docStates*:
  1. **For each** *nestedHistory* of *docState*'s [nested histories<sup>p1007</sup>](#):
    1. If *nestedHistory*'s [id<sup>p1007</sup>](#) equals *navigable*'s [id<sup>p989</sup>](#), return *nestedHistory*'s [entries<sup>p1007</sup>](#).
    2. For each *entry* of *nestedHistory*'s [entries<sup>p1007</sup>](#), **append** *entry*'s [document state<sup>p1005</sup>](#) to *docStates*.

7. **Assert**: this step is not reached.

To **get session history entries for the navigation API** of a [navigable](#)<sup>p989</sup> *navigable* given an integer *targetStep*:

1. Let *rawEntries* be the result of [getting session history entries](#)<sup>p1010</sup> for *navigable*.
2. Let *entriesForNavigationAPI* be a new empty [list](#).
3. Let *startingIndex* be the index of the [session history entry](#)<sup>p1005</sup> in *rawEntries* who has the greatest [step](#)<sup>p1005</sup> less than or equal to *targetStep*.

**Note**

See [this example](#)<sup>p1048</sup> to understand why it's the greatest step less than or equal to *targetStep*.

4. **Append** *rawEntries*[*startingIndex*] to *entriesForNavigationAPI*.
5. Let *startingOrigin* be *rawEntries*[*startingIndex*]'s [document state](#)<sup>p1005</sup>'s [origin](#)<sup>p1006</sup>.
6. Let *i* be *startingIndex* – 1.
7. While *i* > 0:
  1. If *rawEntries*[*i*]'s [document state](#)<sup>p1005</sup>'s [origin](#)<sup>p1006</sup> is not [same origin](#)<sup>p899</sup> with *startingOrigin*, then **break**.
  2. **Prepend** *rawEntries*[*i*] to *entriesForNavigationAPI*.
  3. Set *i* to *i* – 1.
8. Set *i* to *startingIndex* + 1.
9. While *i* < *rawEntries*'s [size](#):
  1. If *rawEntries*[*i*]'s [document state](#)<sup>p1005</sup>'s [origin](#)<sup>p1006</sup> is not [same origin](#)<sup>p899</sup> with *startingOrigin*, then **break**.
  2. **Append** *rawEntries*[*i*] to *entriesForNavigationAPI*.
  3. Set *i* to *i* + 1.
10. Return *entriesForNavigationAPI*.

To **clear the forward session history** of a [traversable navigable](#)<sup>p990</sup> *navigable*:

1. **Assert**: this is running within *navigable*'s [session history traversal queue](#)<sup>p990</sup>.
2. Let *step* be the *navigable*'s [current session history step](#)<sup>p990</sup>.
3. Let *entryLists* be the [ordered set](#) « *navigable*'s [session history entries](#)<sup>p990</sup> ».
4. **For each** *entryList* of *entryLists*:
  1. **Remove** every [session history entry](#)<sup>p1005</sup> from *entryList* that has a [step](#)<sup>p1005</sup> greater than *step*.
  2. **For each** *entry* of *entryList*:
    1. **For each** *nestedHistory* of *entry*'s [document state](#)<sup>p1005</sup>'s [nested histories](#)<sup>p1007</sup>, **append** *nestedHistory*'s [entries list](#)<sup>p1007</sup> to *entryLists*.

To **get all used history steps** that are part of [traversable navigable](#)<sup>p990</sup> *traversable*:

1. **Assert**: this is running within *traversable*'s [session history traversal queue](#)<sup>p990</sup>.
2. Let *steps* be an empty [ordered set](#) of non-negative integers.
3. Let *entryLists* be the [ordered set](#) « *traversable*'s [session history entries](#)<sup>p990</sup> ».
4. **For each** *entryList* of *entryLists*:
  1. **For each** *entry* of *entryList*:
    1. **Append** *entry*'s [step](#)<sup>p1005</sup> to *steps*.

2. For each *nestedHistory* of entry's [document state](#)<sup>p1005</sup>'s [nested histories](#)<sup>p1007</sup>, [append](#) *nestedHistory*'s [entries list](#)<sup>p1007</sup> to *entryLists*.

5. Return *steps*, [sorted](#).

## 7.4.2 Navigation § p1012

Certain actions cause a [navigable](#)<sup>p989</sup> to [navigate](#)<sup>p1014</sup> to a new resource.

### Example

For example, [following a hyperlink](#)<sup>p309</sup>, [form submission](#)<sup>p629</sup>, and the [window.open\(\)](#)<sup>p926</sup> and [location.assign\(\)](#)<sup>p942</sup> methods can all cause navigation.

### Note

Although in this standard the word "navigation" refers specifically to the [navigate](#)<sup>p1014</sup> algorithm, this doesn't always line up with web developer or user perceptions. For example:

- The [URL and history update steps](#)<sup>p1028</sup> are often used during so-called "single-page app navigations" or "same-document navigations", but they do not trigger the [navigate](#)<sup>p1014</sup> algorithm.
- [Reloads](#)<sup>p1027</sup> and [traversals](#)<sup>p1028</sup> are sometimes talked about as a type of navigation, since all three will often [attempt to populate the history entry's document](#)<sup>p1029</sup> and thus could perform navigational fetches. See, e.g., the APIs exposed [Navigation Timing](#). But they have their own entry point algorithms, separate from the [navigate](#)<sup>p1014</sup> algorithm. [\[NAVIGATIONTIMING\]](#)<sup>p1480</sup>
- Although [fragment navigations](#)<sup>p1021</sup> are always done through the [navigate](#)<sup>p1014</sup> algorithm, a user might perceive them as more like jumping around a single page, than as a true navigation.

### 7.4.2.1 Supporting concepts § p1012

Before we can jump into the [navigation algorithm](#)<sup>p1014</sup> itself, we need to establish several important structures that it uses.

The **source snapshot params struct** is used to capture data from a [Document](#)<sup>p130</sup> initiating a navigation. It is snapshotted at the beginning of a navigation and used throughout the navigation's lifetime. It has the following [items](#):

#### **has transient activation**

a boolean

#### **sandboxing flags**

a [sandboxing flag set](#)<sup>p914</sup>

#### **allows downloading**

a boolean

#### **fetch client**

an [environment settings object](#)<sup>p1076</sup>, only to be used as a [request client](#)

#### **source policy container**

a [policy container](#)<sup>p917</sup>

To **snapshot source snapshot params** given a [Document](#)<sup>p130</sup> *sourceDocument*, return a new [source snapshot params](#)<sup>p1012</sup> with

#### **has transient activation**<sup>p1012</sup>

true if *sourceDocument*'s [relevant global object](#)<sup>p1083</sup> has [transient activation](#)<sup>p830</sup>; otherwise false

#### **sandboxing flags**<sup>p1012</sup>

*sourceDocument*'s [active sandboxing flag set](#)<sup>p917</sup>

#### **allows downloading**<sup>p1012</sup>

false if *sourceDocument*'s [active sandboxing flag set](#)<sup>p917</sup> has the [sandboxed downloads browsing context flag](#)<sup>p916</sup> set; otherwise true

## **fetch client**<sup>p1012</sup>

sourceDocument's [relevant settings object](#)<sup>p1083</sup>

## **source policy container**<sup>p1012</sup>

sourceDocument's [policy container](#)<sup>p131</sup>

The **target snapshot params struct** is used to capture data from a [navigable](#)<sup>p989</sup> being navigated. Like [source snapshot params](#)<sup>p1012</sup>, it is snapshotted at the beginning of a navigation and used throughout the navigation's lifetime. It has the following [items](#):

### **sandboxing flags**

a [sandboxing flag set](#)<sup>p914</sup>

To **snapshot target snapshot params** given a [navigable](#)<sup>p989</sup> *targetNavigable*, return a new [target snapshot params](#)<sup>p1013</sup> with [sandboxing flags](#)<sup>p1013</sup> set to the result of [determining the creation sandboxing flags](#)<sup>p917</sup> given *targetNavigable*'s [active browsing context](#)<sup>p989</sup> and *targetNavigable*'s [container](#)<sup>p991</sup>.

Much of the navigation process is concerned with determining how to create a new [Document](#)<sup>p130</sup>, which ultimately happens in the [create and initialize a Document object](#)<sup>p1056</sup> algorithm. The parameters to that algorithm are tracked via a **navigation params struct**, which has the following [items](#):

### **id**

null or a [navigation ID](#)<sup>p1014</sup>

### **navigable**

the [navigable](#)<sup>p989</sup> to be navigated

### **request**

null or a [request](#) that started the navigation

### **response**

a [response](#) that ultimately was navigated to (potentially a [network error](#))

### **fetch controller**

null or a [fetch controller](#)

### **commit early hints**

null or an algorithm accepting a [Document](#)<sup>p130</sup>, once it has been created

### **COOP enforcement result**

an [opener policy enforcement result](#)<sup>p906</sup>, used for reporting and potentially for causing a [browsing context group switch](#)<sup>p905</sup>

### **reserved environment**

null or an [environment](#)<sup>p1075</sup> reserved for the new [Document](#)<sup>p130</sup>

### **origin**

an [origin](#)<sup>p898</sup> to use for the new [Document](#)<sup>p130</sup>

### **policy container**

a [policy container](#)<sup>p917</sup> to use for the new [Document](#)<sup>p130</sup>

### **final sandboxing flag set**

a [sandboxing flag set](#)<sup>p914</sup> to impose on the new [Document](#)<sup>p130</sup>

### **opener policy**

an [opener policy](#)<sup>p904</sup> to use for the new [Document](#)<sup>p130</sup>

### **navigation timing type**

a [NavigationTimingType](#) used for [creating the navigation timing entry](#) for the new [Document](#)<sup>p130</sup>

### **about base URL**

a [URL](#) or null used to populate the new [Document](#)<sup>p130</sup>'s [about base URL](#)<sup>p131</sup>

## **Note**

Once a [navigation params](#)<sup>p1013</sup> struct is created, this standard does not mutate any of its [items](#). They are only passed onward to other algorithms.

A **navigation ID** is a UUID string generated during navigation. It is used to interface with the *WebDriver BiDi* specification as well as to track the [ongoing navigation](#)<sup>p1027</sup>. [\[WEBDRIVERBIDI\]](#)<sup>p1483</sup>

After [Document](#)<sup>p130</sup> creation, the relevant [traversable navigable](#)<sup>p990</sup>'s [session history](#)<sup>p990</sup> gets updated. The [NavigationHistoryBehavior](#)<sup>p952</sup> enumeration is used to indicate the desired type of session history update to the [navigate](#)<sup>p1014</sup> algorithm. It is one of the following:

#### "push"

A regular navigation which adds a new [session history entry](#)<sup>p1005</sup>, and will [clear the forward session history](#)<sup>p1011</sup>.

#### "replace"

A navigation that will replace the [active session history entry](#)<sup>p989</sup>.

#### "auto"

The default value, which will be converted very early in the [navigate](#)<sup>p1014</sup> algorithm into "[push](#)<sup>p1014</sup>" or "[replace](#)<sup>p1014</sup>". Usually it becomes "[push](#)<sup>p1014</sup>", but under [certain circumstances](#)<sup>p1015</sup> it becomes "[replace](#)<sup>p1014</sup>" instead.

A **history handling behavior** is a [NavigationHistoryBehavior](#)<sup>p952</sup> that is either "[push](#)<sup>p1014</sup>" or "[replace](#)<sup>p1014</sup>", i.e., that has been resolved away from any initial "[auto](#)<sup>p1014</sup>" value.

The navigation must be a replace, given a [URL](#) *url* and a [Document](#)<sup>p130</sup> *document*, if any of the following are true:

- *url*'s [scheme](#) is "[javascript](#)<sup>p1019</sup>"; or
- *document*'s [is initial about:blank](#)<sup>p131</sup> is true.

#### Note

*Other cases that often, but not always, force a "[replace](#)<sup>p1014</sup>" navigation are:*

- *if the [Document](#)<sup>p130</sup> is not [completely loaded](#)<sup>p1063</sup>; or*
- *if the target [URL](#) equals the [Document](#)<sup>p130</sup>'s [URL](#).*

Various parts of the platform track whether a user is involved in a navigation. A **user navigation involvement** is one of the following:

#### "browser UI"

The navigation was initiated by the user via browser UI mechanisms.

#### "activation"

The navigation was initiated by the user via the [activation behavior](#) of an element.

#### "none"

The navigation was not initiated by the user.

For convenience at certain call sites, the **user navigation involvement** for an [Event](#) *event* is defined as follows:

1. [Assert](#): this algorithm is being called as part of an [activation behavior](#) definition.
2. [Assert](#): *event*'s [type](#) is "[click](#)".
3. If *event*'s [isTrusted](#) is initialized to true, then return "[activation](#)<sup>p1014</sup>".
4. Return "[none](#)<sup>p1014</sup>".

### 7.4.2.2 Beginning navigation <sup>p10</sup>

14

To **navigate** a [navigable](#)<sup>p989</sup> *navigable* to a [URL](#) *url* using a [Document](#)<sup>p130</sup> *sourceDocument*, with an optional [POST resource](#)<sup>p1007</sup>, string, or null **documentResource** (default null), an optional [response](#)-or-null **response** (default null), an optional boolean **exceptionsEnabled** (default false), an optional [NavigationHistoryBehavior](#)<sup>p952</sup> **historyHandling** (default "[auto](#)<sup>p1014</sup>"), an optional [serialized state](#)<sup>p1006</sup>-or-null **navigationAPIState** (default null), an optional [entry list](#)<sup>p632</sup> or null **formDataEntryList** (default null), an optional [referrer policy](#) **referrerPolicy** (default the empty string), and an optional [user navigation involvement](#)<sup>p1014</sup> **userInvolvement**

(default "[none](#)<sup>p1014</sup>");

1. Let `cspNavigationType` be "form-submission" if `formDataEntryList` is non-null; otherwise "other".
2. Let `sourceSnapshotParams` be the result of [snapshotting source snapshot params](#)<sup>p1012</sup> given `sourceDocument`.
3. Let `initiatorOriginSnapshot` be `sourceDocument`'s [origin](#).
4. Let `initiatorBaseURLSnapshot` be `sourceDocument`'s [document base URL](#)<sup>p96</sup>.
5. If `sourceDocument`'s [node navigable](#)<sup>p989</sup> is not [allowed by sandboxing to navigate](#)<sup>p1025</sup> `navigable` given `sourceSnapshotParams`, then:
  1. If `exceptionsEnabled` is true, then throw a "[SecurityError](#)" [DOMException](#).
  2. Return.
6. Let `navigationId` be the result of [generating a random UUID](#). [[WEBCRYPTO](#)]<sup>p1483</sup>
7. If the [surrounding agent](#) is equal to `navigable`'s [active document](#)<sup>p989</sup>'s [relevant agent](#)<sup>p1073</sup>, then continue these steps. Otherwise, [queue a global task](#)<sup>p1125</sup> on the [navigation and traversal task source](#)<sup>p1134</sup> given `navigable`'s [active window](#)<sup>p989</sup> to continue these steps.

#### Note

We do this because we are about to look at a lot of properties of `navigable`'s [active document](#)<sup>p989</sup>, which are in theory only accessible over in the appropriate [event loop](#)<sup>p1123</sup>. (But, we do not want to unconditionally queue a task, since — for example — same-event-loop [fragment navigations](#)<sup>p1021</sup> need to take effect synchronously.)

Another implementation strategy would be to replicate the relevant information across event loops, or into a canonical "browser process", so that it can be consulted without queueing a task. This could give different results than what we specify here in edge cases, where the relevant properties have changed over in the target event loop but not yet been replicated. Further testing is needed to determine which of these strategies best matches browser behavior, in such racy edge cases.

8. If `navigable`'s [active document](#)<sup>p989</sup>'s [unload counter](#)<sup>p1064</sup> is greater than 0, then invoke [WebDriver BiDi navigation failed](#) with a [WebDriver BiDi navigation status](#) whose `id` is `navigationId`, `status` is "[canceled](#)", and `url` is `url`, and return.
9. Let `container` be `navigable`'s [container](#)<sup>p991</sup>.
10. If `container` is an [iframe](#)<sup>p390</sup> element and [will lazy load element steps](#)<sup>p101</sup> given `container` returns true, then [stop intersection-observing a lazy loading element](#)<sup>p102</sup> `container` and set `container`'s [lazy load resumption steps](#)<sup>p101</sup> to null.
11. If `historyHandling` is "[auto](#)<sup>p1014</sup>", then:
  1. If `url` [equals](#) `navigable`'s [active document](#)<sup>p989</sup>'s [URL](#), and `initiatorOriginSnapshot` is [same origin](#)<sup>p899</sup> with `targetNavigable`'s [active document](#)<sup>p989</sup>'s [origin](#), then set `historyHandling` to "[replace](#)<sup>p1014</sup>".
  2. Otherwise, set `historyHandling` to "[push](#)<sup>p1014</sup>".
12. If [the navigation must be a replace](#)<sup>p1014</sup> given `url` and `navigable`'s [active document](#)<sup>p989</sup>, then set `historyHandling` to "[replace](#)<sup>p1014</sup>".
13. If all of the following are true:
  - `documentResource` is null;
  - `response` is null;
  - `url` [equals](#) `navigable`'s [active session history entry](#)<sup>p989</sup>'s [URL](#)<sup>p1005</sup> with [exclude fragments](#) set to true; and
  - `url`'s [fragment](#) is non-null,then:
  1. [Navigate to a fragment](#)<sup>p1021</sup> given `navigable`, `url`, `historyHandling`, `userInvolvement`, `navigationAPIState`, and `navigationId`.
  2. Return.
14. If `navigable`'s [parent](#)<sup>p989</sup> is non-null, then set `navigable`'s [is delaying load events](#)<sup>p989</sup> to true.

15. Let *targetBrowsingContext* be *navigable*'s [active browsing context](#)<sup>p989</sup>.
16. Let *targetSnapshotParams* be the result of [snapshotting target snapshot params](#)<sup>p1013</sup> given *navigable*.
17. Invoke [WebDriver BiDi navigation started](#) with *targetBrowsingContext*, and a new [WebDriver BiDi navigation status](#) whose *id* is *navigationId*, *status* is "pending", and *url* is *url*.
18. If *navigable*'s [ongoing navigation](#)<sup>p1027</sup> is "traversal", then:
  1. Invoke [WebDriver BiDi navigation failed](#) with *targetBrowsingContext* and a new [WebDriver BiDi navigation status](#) whose *id* is *navigationId*, *status* is "canceled", and *url* is *url*.
  2. Return.

**Note**

Any attempts to navigate a [navigable](#)<sup>p989</sup> that is currently [traversing](#)<sup>p1040</sup> are ignored.

19. [Set the ongoing navigation](#)<sup>p1027</sup> for *navigable* to *navigationId*.

**Note**

This will have the effect of aborting other ongoing navigations of *navigable*, since at certain points during navigation changes to the [ongoing navigation](#)<sup>p1027</sup> will cause further work to be abandoned.

20. If *url*'s *scheme* is "javascript"<sup>p1019</sup>, then:
  1. [Queue a global task](#)<sup>p1125</sup> on the [navigation and traversal task source](#)<sup>p1134</sup> given *navigable*'s [active window](#)<sup>p989</sup> to [navigate to a javascript: URL](#)<sup>p1019</sup> given *navigable*, *url*, *historyHandling*, *initiatorOriginSnapshot*, and *cspNavigationType*.
  2. Return.
21. If all of the following are true:
  - *userInvolvement* is not "browser UI"<sup>p1014</sup>;
  - *navigable*'s [active document](#)<sup>p989</sup>'s *origin* is [same origin-domain](#)<sup>p899</sup> with *sourceDocument*'s *origin*;
  - *navigable*'s [active document](#)<sup>p989</sup>'s *is initial about:blank*<sup>p131</sup> is false; and
  - *url*'s *scheme* is a [fetch scheme](#),

then:

1. Let *navigation* be *navigable*'s [active window](#)<sup>p989</sup>'s [navigation API](#)<sup>p952</sup>.
2. Let *entryListForFiring* be *formDataEntryList* if *documentResource* is a [POST resource](#)<sup>p1007</sup>; otherwise, null.
3. Let *navigationAPIStateForFiring* be *navigationAPIState* if *navigationAPIState* is not null; otherwise, [StructuredSerializeForStorage](#)<sup>p122</sup> (undefined).
4. Let *continue* be the result of [firing a push/replace/reload navigate event](#)<sup>p974</sup> at *navigation* with [navigationType](#)<sup>p974</sup> set to *historyHandling*, [isSameDocument](#)<sup>p974</sup> set to false, [userInvolvement](#)<sup>p974</sup> set to *userInvolvement*, [formDataEntryList](#)<sup>p975</sup> set to *entryListForFiring*, [destinationURL](#)<sup>p974</sup> set to *url*, and [navigationAPIState](#)<sup>p975</sup> set to *navigationAPIStateForFiring*.
5. If *continue* is false, then return.

**Note**

It is possible for navigations with *userInvolvement* of "browser UI"<sup>p1014</sup> or initiated by a [cross origin-domain](#)<sup>p899</sup> *sourceDocument* to fire [navigate](#)<sup>p1472</sup> events, if they go through the earlier [navigate to a fragment](#)<sup>p1021</sup> path.

22. [In parallel](#)<sup>p43</sup>, run these steps:
  1. Let *unloadPromptCanceled* be the result of [checking if unloading is canceled](#)<sup>p1025</sup> for *navigable*'s [active document](#)<sup>p989</sup>'s [inclusive descendant navigables](#)<sup>p994</sup>.
  2. If *unloadPromptCanceled* is true, or *navigable*'s [ongoing navigation](#)<sup>p1027</sup> is no longer *navigationId*, then:
    1. Invoke [WebDriver BiDi navigation failed](#) with *targetBrowsingContext* and a new [WebDriver BiDi](#)

[navigation status](#) whose [id](#) is [navigationId](#), [status](#) is "canceled", and [url](#) is [url](#).

2. Abort these steps.
3. [Queue a global task](#)<sup>p1125</sup> on the [navigation and traversal task source](#)<sup>p1134</sup> given [navigable's active window](#)<sup>p989</sup> to [abort a document and its descendants](#)<sup>p1067</sup> given [navigable's active document](#)<sup>p989</sup>.
4. Let [documentState](#) be a new [document state](#)<sup>p1006</sup> with
  - [request referrer policy](#)<sup>p1006</sup>  
[referrerPolicy](#)
  - [initiator origin](#)<sup>p1006</sup>  
[initiatorOriginSnapshot](#)
  - [resource](#)<sup>p1007</sup>  
[documentResource](#)
  - [navigable target name](#)<sup>p1007</sup>  
[navigable's target name](#)<sup>p989</sup>

**Note**

The [navigable target name](#)<sup>p1007</sup> can get cleared under various conditions later in the navigation process, before the document state is finalized.

5. If [url](#) matches [about:blank](#)<sup>p96</sup> or is [about:srcdoc](#)<sup>p96</sup>, then:
  1. Set [documentState's origin](#)<sup>p1006</sup> to [initiatorOriginSnapshot](#).
  2. Set [documentState's about base URL](#)<sup>p1007</sup> to [initiatorBaseURLSnapshot](#).
6. Let [historyEntry](#) be a new [session history entry](#)<sup>p1005</sup>, with its [URL](#)<sup>p1005</sup> set to [url](#) and its [document state](#)<sup>p1005</sup> set to [documentState](#).
7. Let [navigationParams](#) be null.
8. If [response](#) is non-null:

**Note**

The [navigate](#)<sup>p1014</sup> algorithm is only supplied with a [response](#) as part of the [object](#)<sup>p402</sup> and [embed](#)<sup>p399</sup> processing models, or for processing parts of [multipart/x-mixed-replace responses](#)<sup>p1061</sup> after the initial response.

1. Let [policyContainer](#) be the result of [determining navigation params policy container](#)<sup>p918</sup> given [response's URL](#), null, a [clone](#)<sup>p917</sup> of the [sourceDocument's policy container](#)<sup>p131</sup>, [navigable's container document](#)<sup>p992</sup>'s [policy container](#)<sup>p131</sup>, and null.
2. Let [finalSandboxFlags](#) be the [union](#) of [targetSnapshotParams's sandboxing flags](#)<sup>p1013</sup> and [policyContainer's CSP list](#)<sup>p917</sup>'s [CSP-derived sandboxing flags](#)<sup>p917</sup>.
3. Let [responseOrigin](#) be the result of [determining the origin](#)<sup>p1001</sup> given [response's URL](#), [finalSandboxFlags](#), and [documentState's initiator origin](#)<sup>p1006</sup>.
4. Let [coop](#) be a new [opener policy](#)<sup>p904</sup>.
5. Let [coopEnforcementResult](#) be a new [opener policy enforcement result](#)<sup>p906</sup> with
  - [url](#)<sup>p906</sup>  
[response's URL](#)
  - [origin](#)<sup>p906</sup>  
[responseOrigin](#)
  - [opener policy](#)<sup>p906</sup>  
[coop](#)
6. Set [navigationParams](#) to a new [navigation params](#)<sup>p1013</sup>, with
  - [id](#)<sup>p1013</sup>  
[navigationId](#)
  - [navigable](#)<sup>p1013</sup>  
[navigable](#)
  - [request](#)<sup>p1013</sup>  
null

[response](#)<sup>p1013</sup>  
*response*  
[fetch controller](#)<sup>p1013</sup>  
*null*  
[commit early hints](#)<sup>p1013</sup>  
*null*  
[COOP enforcement result](#)<sup>p1013</sup>  
*coopEnforcementResult*  
[reserved environment](#)<sup>p1013</sup>  
*null*  
[origin](#)<sup>p1013</sup>  
*responseOrigin*  
[policy container](#)<sup>p1013</sup>  
*policyContainer*  
[final sandboxing flag set](#)<sup>p1013</sup>  
*finalSandboxFlags*  
[opener policy](#)<sup>p1013</sup>  
*coop*  
[navigation timing type](#)<sup>p1013</sup>  
*"navigate"*  
[about base URL](#)<sup>p1013</sup>  
*documentState's [about base URL](#)*<sup>p1007</sup>

9. [Attempt to populate the history entry's document](#)<sup>p1029</sup> for *historyEntry*, given *navigable*, *"navigate"*, *sourceSnapshotParams*, *targetSnapshotParams*, *navigationId*, *navigationParams*, *cspNavigationType*, with *allowPOST*<sup>p1029</sup> set to true and *completionSteps*<sup>p1029</sup> set to the following step:
  1. [Append session history traversal steps](#)<sup>p1008</sup> to *navigable*'s [traversable](#)<sup>p990</sup> to [finalize a cross-document navigation](#)<sup>p1018</sup> given *navigable*, *historyHandling*, and *historyEntry*.

#### 7.4.2.3 Ending navigation <sup>p10</sup><sub>18</sub>

Although the usual cross-document navigation case will first foray into [populating a session history entry](#)<sup>p1029</sup> with a *Document*<sup>p130</sup>, all navigations that don't get aborted will ultimately end up calling into one of the below algorithms.

##### 7.4.2.3.1 The usual cross-document navigation case <sup>p10</sup><sub>18</sub>

To **finalize a cross-document navigation** given a [navigable](#)<sup>p989</sup> *navigable*, [history handling behavior](#)<sup>p1014</sup> *historyHandling*, and [session history entry](#)<sup>p1005</sup> *historyEntry*:

1. **Assert**: this is running on *navigable*'s [traversable navigable's](#)<sup>p990</sup> [session history traversal queue](#)<sup>p990</sup>.
2. Set *navigable*'s [is delaying load events](#)<sup>p989</sup> to false.
3. If *historyEntry*'s [document](#)<sup>p1005</sup> is null, then return.

#### Note

This means that [attempting to populate the history entry's document](#)<sup>p1029</sup> ended up not creating a document, as a result of e.g., the navigation being canceled by a subsequent navigation, a 204 No Content response, etc.

4. If all of the following are true:
  - *navigable*'s [parent](#)<sup>p989</sup> is null;
  - *historyEntry*'s [document](#)<sup>p1005</sup>'s [browsing context](#)<sup>p999</sup> is not an [auxiliary browsing context](#)<sup>p999</sup> whose [opener browsing context](#)<sup>p998</sup> is non-null; and
  - *historyEntry*'s [document](#)<sup>p1005</sup>'s [origin](#) is not *navigable*'s [active document](#)<sup>p989</sup>'s [origin](#),
 then set *historyEntry*'s [document state](#)<sup>p1005</sup>'s [navigable target name](#)<sup>p1007</sup> to the empty string.

5. Let *entryToReplace* be *navigable*'s [active session history entry](#)<sup>p989</sup> if *historyHandling* is "[replace](#)<sup>p1014</sup>", otherwise null.
  6. Let *traversable* be *navigable*'s [traversable navigable](#)<sup>p990</sup>.
  7. Let *targetStep* be null.
  8. Let *targetEntries* be the result of [getting session history entries](#)<sup>p1010</sup> for *navigable*.
  9. If *entryToReplace* is null, then:
    1. [Clear the forward session history](#)<sup>p1011</sup> of *traversable*.
    2. Set *targetStep* to *traversable*'s [current session history step](#)<sup>p990</sup> + 1.
    3. Set *historyEntry*'s [step](#)<sup>p1005</sup> to *targetStep*.
    4. [Append](#) *historyEntry* to *targetEntries*.
- Otherwise:
1. [Replace](#) *entryToReplace* with *historyEntry* in *targetEntries*.
  2. Set *historyEntry*'s [step](#)<sup>p1005</sup> to *entryToReplace*'s [step](#)<sup>p1005</sup>.
  3. If *historyEntry*'s [document state](#)<sup>p1005</sup>'s [origin](#)<sup>p1006</sup> is [same origin](#)<sup>p899</sup> with *entryToReplace*'s [document state](#)<sup>p1005</sup>'s [origin](#)<sup>p1006</sup>, then set *historyEntry*'s [navigation API key](#)<sup>p1005</sup> to *entryToReplace*'s [navigation API key](#)<sup>p1005</sup>.
  4. Set *targetStep* to *traversable*'s [current session history step](#)<sup>p990</sup>.
10. [Apply the push/replace history step](#)<sup>p1040</sup> *targetStep* to *traversable* given *historyHandling*.

#### 7.4.2.3.2 The **javascript:** URL special case §<sup>p10</sup> 19

[javascript:](#)<sup>p1019</sup> URLs have a [dedicated label](#) on the issue tracker documenting various problems with their specification.

To **navigate to a javascript: URL**, given a [navigable](#)<sup>p989</sup> *targetNavigable*, a [URL](#) *url*, a [history handling behavior](#)<sup>p1014</sup> *historyHandling*, an [origin](#)<sup>p898</sup> *initiatorOrigin*, and a string *cspNavigationType*:

1. [Assert](#): *historyHandling* is "[replace](#)<sup>p1014</sup>".
2. [Set the ongoing navigation](#)<sup>p1027</sup> for *targetNavigable* to null.
3. If *initiatorOrigin* is not [same origin-domain](#)<sup>p899</sup> with *targetNavigable*'s [active document](#)<sup>p989</sup>'s [origin](#), then return.
4. Let *request* be a new [request](#) whose [URL](#) is *url*.

#### Note

*This is a synthetic [request](#) solely for plumbing into the next step. It will never hit the network.*

5. If the result of [should navigation request of type be blocked by Content Security Policy?](#) given *request* and *cspNavigationType* is "Blocked", then return. [\[CSP\]](#)<sup>p1476</sup>
6. Let *newDocument* be the result of [evaluating a javascript: URL](#)<sup>p1020</sup> given *targetNavigable*, *url*, and *initiatorOrigin*.
7. If *newDocument* is null, then return.

#### Note

*In this case, some JavaScript code was executed, but no new [Document](#)<sup>p130</sup> was created, so we will not perform a navigation.*

8. [Assert](#): *initiatorOrigin* is *newDocument*'s [origin](#).
9. Let *entryToReplace* be *targetNavigable*'s [active session history entry](#)<sup>p989</sup>.
10. Let *oldDocState* be *entryToReplace*'s [document state](#)<sup>p1005</sup>.

11. Let *documentState* be a new [document state](#)<sup>p1006</sup> with

**document**<sup>p1006</sup>

*newDocument*

**history policy container**<sup>p1006</sup>

a [clone](#)<sup>p917</sup> of the *oldDocState*'s [history policy container](#)<sup>p1006</sup> if it is non-null; null otherwise

**request referrer**<sup>p1006</sup>

*oldDocState*'s [request referrer](#)<sup>p1006</sup>

**request referrer policy**<sup>p1006</sup>

*oldDocState*'s [request referrer policy](#)<sup>p1006</sup> or should this be the *referrerPolicy* that was passed to [navigate](#)<sup>p1014</sup>?

**initiator origin**<sup>p1006</sup>

*initiatorOrigin*

**origin**<sup>p1006</sup>

*initiatorOrigin*

**about base URL**<sup>p1007</sup>

*oldDocState*'s [about base URL](#)<sup>p1007</sup>

**resource**<sup>p1007</sup>

null

**ever populated**<sup>p1007</sup>

true

**navigable target name**<sup>p1007</sup>

*oldDocState*'s [navigable target name](#)<sup>p1007</sup>

12. Let *historyEntry* be a new [session history entry](#)<sup>p1005</sup>, with

**URL**<sup>p1005</sup>

*entryToReplace*'s [URL](#)<sup>p1005</sup>

**document state**<sup>p1005</sup>

*documentState*

#### Note

For the [URL](#)<sup>p1005</sup>, we do not use url, i.e. the actual [javascript:](#)<sup>p1019</sup> URL that the [navigate](#)<sup>p1014</sup> algorithm was called with. This means [javascript:](#)<sup>p1019</sup> URLs are never stored in session history, and so can never be traversed to.

13. [Append session history traversal steps](#)<sup>p1008</sup> to *targetNavigable*'s [traversable](#)<sup>p990</sup> to [finalize a cross-document navigation](#)<sup>p1018</sup> with *targetNavigable*, *historyHandling*, and *historyEntry*.

To **evaluate a javascript: URL** given a [navigable](#)<sup>p989</sup> *targetNavigable*, a [URL](#) *url*, and an [origin](#)<sup>p898</sup> *newDocumentOrigin*:

1. Let *urlString* be the result of running the [URL serializer](#) on *url*.
2. Let *encodedScriptSource* be the result of removing the leading "javascript:" from *urlString*.
3. Let *scriptSource* be the [UTF-8 decoding](#) of the [percent-decoding](#) of *encodedScriptSource*.
4. Let *settings* be *targetNavigable*'s [active document](#)<sup>p989</sup>'s [relevant settings object](#)<sup>p1083</sup>.
5. Let *baseURL* be *settings*'s [API base URL](#)<sup>p1076</sup>.
6. Let *script* be the result of [creating a classic script](#)<sup>p1093</sup> given *scriptSource*, *settings*, *baseURL*, and the [default script fetch options](#)<sup>p1086</sup>.
7. Let *evaluationStatus* be the result of [running the classic script](#)<sup>p1096</sup> *script*.
8. Let *result* be null.
9. If *evaluationStatus* is a normal completion, and *evaluationStatus*.[[Value]] is a String, then set *result* to *evaluationStatus*.[[Value]].
10. Otherwise, return null.
11. Let *response* be a new [response](#) with

**URL**

*targetNavigable*'s [active document](#)<sup>p989</sup>'s [URL](#)

**header list**

« ([Content-Type](#)<sup>p98</sup>, `text/html; charset=utf-8`) »

## body

the [UTF-8 encoding](#) of result, as a body

## Note

The encoding to UTF-8 means that unpaired [surrogates](#) will not roundtrip, once the HTML parser decodes the response body.

12. Let *policyContainer* be *targetNavigable*'s [active document](#)<sup>p989</sup>'s [policy container](#)<sup>p131</sup>.
13. Let *finalSandboxFlags* be *policyContainer*'s [CSP list](#)<sup>p917</sup>'s [CSP-derived sandboxing flags](#)<sup>p917</sup>.
14. Let *coop* be *targetNavigable*'s [active document](#)<sup>p989</sup>'s [opener policy](#)<sup>p131</sup>.
15. Let *coopEnforcementResult* be a new [opener policy enforcement result](#)<sup>p906</sup> with

[url](#)<sup>p906</sup>  
*url*  
[origin](#)<sup>p906</sup>  
*newDocumentOrigin*  
[opener policy](#)<sup>p906</sup>  
*coop*

16. Let *navigationParams* be a new [navigation params](#)<sup>p1013</sup>, with

[id](#)<sup>p1013</sup>  
*navigationId*  
[navigable](#)<sup>p1013</sup>  
*targetNavigable*  
[request](#)<sup>p1013</sup>  
null this will cause the referrer of the resulting Document<sup>p130</sup> to be null; is that correct?  
[response](#)<sup>p1013</sup>  
*response*  
[fetch controller](#)<sup>p1013</sup>  
null  
[commit early hints](#)<sup>p1013</sup>  
null  
[COOP enforcement result](#)<sup>p1013</sup>  
*coopEnforcementResult*  
[reserved environment](#)<sup>p1013</sup>  
null  
[origin](#)<sup>p1013</sup>  
*newDocumentOrigin*  
[policy container](#)<sup>p1013</sup>  
*policyContainer*  
[final sandboxing flag set](#)<sup>p1013</sup>  
*finalSandboxFlags*  
[opener policy](#)<sup>p1013</sup>  
*coop*  
[navigation timing type](#)<sup>p1013</sup>  
"navigate"  
[about base URL](#)<sup>p1013</sup>  
*targetNavigable*'s [active document](#)<sup>p989</sup>'s [about base URL](#)<sup>p131</sup>

17. Return the result of [loading an HTML document](#)<sup>p1059</sup> given *navigationParams*.

### 7.4.2.3.3 Fragment navigations §<sup>p10</sup> 21

To **navigate to a fragment** given a [navigable](#)<sup>p989</sup> *navigable*, a [URL](#) *url*, a [history handling behavior](#)<sup>p1014</sup> *historyHandling*, a [user navigation involvement](#)<sup>p1014</sup> *userInvolvement*, a [serialized state](#)<sup>p1006</sup>-or-null *navigationAPIState*, and a [navigation ID](#)<sup>p1014</sup> *navigationId*:

1. Let *navigation* be *navigable*'s [active window](#)<sup>p989</sup>'s [navigation API](#)<sup>p952</sup>.
2. Let *destinationNavigationAPIState* be *navigable*'s [active session history entry](#)<sup>p989</sup>'s [navigation API state](#)<sup>p1005</sup>.

3. If `navigationAPIState` is not null, then set `destinationNavigationAPIState` to `navigationAPIState`.
4. Let `continue` be the result of [firing a push/replace/reload navigate event](#)<sup>p974</sup> at `navigation` with [navigationType](#)<sup>p974</sup> set to `historyHandling`, [isSameDocument](#)<sup>p974</sup> set to true, [userInvolvement](#)<sup>p974</sup> set to `userInvolvement`, [destinationURL](#)<sup>p974</sup> set to `url`, and [navigationAPIState](#)<sup>p975</sup> set to `destinationNavigationAPIState`.
5. If `continue` is false, then return.
6. Let `historyEntry` be a new [session history entry](#)<sup>p1005</sup>, with

[URL](#)<sup>p1005</sup>  
`url`  
[document state](#)<sup>p1005</sup>  
`navigable's active session history entry`<sup>p989</sup>'s [document state](#)<sup>p1005</sup>  
[navigation API state](#)<sup>p1005</sup>  
`destinationNavigationAPIState`  
[scroll restoration mode](#)<sup>p1005</sup>  
`navigable's active session history entry`<sup>p989</sup>'s [scroll restoration mode](#)<sup>p1005</sup>

#### Note

For navigations performed with [navigation.navigate\(\)](#)<sup>p960</sup>, the value provided by the [state](#)<sup>p952</sup> option is used for the new [navigation API state](#)<sup>p1005</sup>. (This will set it to the serialization of undefined, if no value is provided for that option.) For other fragment navigations, including user-initiated ones, the [navigation API state](#)<sup>p1005</sup> is carried over from the previous entry.

The [classic history API state](#)<sup>p1005</sup> is never carried over.

7. Let `entryToReplace` be `navigable's active session history entry`<sup>p989</sup> if `historyHandling` is "[replace](#)<sup>p1014</sup>", otherwise null.
8. Let `history` be `navigable's active document`<sup>p989</sup>'s [history object](#)<sup>p945</sup>.
9. Let `scriptHistoryIndex` be `history's index`<sup>p946</sup>.
10. Let `scriptHistoryLength` be `history's length`<sup>p946</sup>.
11. If `historyHandling` is "[push](#)<sup>p1014</sup>", then:
  1. Set `history's state`<sup>p946</sup> to null.
  2. Increment `scriptHistoryIndex`.
  3. Set `scriptHistoryLength` to `scriptHistoryIndex` + 1.
12. Set `navigable's active document`<sup>p989</sup>'s [URL](#) to `url`.
13. Set `navigable's active session history entry`<sup>p989</sup> to `historyEntry`.
14. [Update document for history step application](#)<sup>p1049</sup> given `navigable's active document`<sup>p989</sup>, `historyEntry`, true, `scriptHistoryIndex`, `scriptHistoryLength`, and `historyHandling`.

#### Note

This algorithm will be called twice as a result of a single fragment navigation: once synchronously, where best-guess values `scriptHistoryIndex` and `scriptHistoryLength` are set, [history.state](#)<sup>p946</sup> is nulled out, and various events are fired; and once asynchronously, where the final values for `index` and `length` are set, [history.state](#)<sup>p946</sup> remains untouched, and no events are fired.

15. [Scroll to the fragment](#)<sup>p1054</sup> given `navigable's active document`<sup>p989</sup>.

#### Note

If the scrolling fails because the [Document](#)<sup>p130</sup> is new and the relevant [ID](#) has not yet been parsed, then the second asynchronous call to [update document for history step application](#)<sup>p1049</sup> will take care of scrolling.

16. Let `traversable` be `navigable's traversable navigable`<sup>p990</sup>.
17. [Append the following session history synchronous navigation steps](#)<sup>p1008</sup> involving `navigable` to `traversable`:
  1. [Finalize a same-document navigation](#)<sup>p1023</sup> given `traversable`, `navigable`, `historyEntry`, `entryToReplace`, and

historyHandling.

2. Invoke [WebDriver BiDi fragment navigated](#) with [navigable's active browsing context<sup>p989</sup>](#) and a new [WebDriver BiDi navigation status](#) whose [id](#) is [navigationId](#), [url](#) is [url](#), and [status](#) is ["complete"](#).

To **finalize a same-document navigation** given a [traversable navigable<sup>p990</sup>](#) [traversable](#), a [navigable<sup>p989</sup>](#) [targetNavigable](#), a [session history entry<sup>p1005</sup>](#) [targetEntry](#), a [session history entry<sup>p1005</sup>](#)-or-null [entryToReplace](#), and a [history handling behavior<sup>p1014</sup>](#) [historyHandling](#):

#### Note

This is used by both [fragment navigations<sup>p1021</sup>](#) and by the [URL and history update steps<sup>p1028</sup>](#), which are the only synchronous updates to session history. By virtue of being synchronous, those algorithms are performed outside of the [top-level traversable<sup>p990</sup>'s session history traversal queue<sup>p990</sup>](#). This puts them out of sync with the [top-level traversable<sup>p990</sup>'s current session history step<sup>p990</sup>](#), so this algorithm is used to resolve conflicts due to race conditions.

1. **Assert**: this is running on [traversable's session history traversal queue<sup>p990</sup>](#).
2. If [targetNavigable's active session history entry<sup>p989</sup>](#) is not [targetEntry](#), then return.
3. Let [targetStep](#) be null.
4. Let [targetEntries](#) be the result of [getting session history entries<sup>p1010</sup>](#) for [targetNavigable](#).
5. If [entryToReplace](#) is null, then:
  1. **Clear the forward session history<sup>p1011</sup>** of [traversable](#).
  2. Set [targetStep](#) to [traversable's current session history step<sup>p990</sup>](#) + 1.
  3. Set [targetEntry's step<sup>p1005</sup>](#) to [targetStep](#).
  4. **Append** [targetEntry](#) to [targetEntries](#).

Otherwise:

1. **Replace** [entryToReplace](#) with [targetEntry](#) in [targetEntries](#).
2. Set [targetEntry's step<sup>p1005</sup>](#) to [entryToReplace's step<sup>p1005</sup>](#).
3. Set [targetStep](#) to [traversable's current session history step<sup>p990</sup>](#).
6. **Apply the push/replace history step<sup>p1040</sup>** [targetStep](#) to [traversable](#) given [historyHandling](#).

#### Note

This is done even for ["replace<sup>p1014</sup>"](#) navigations, as it resolves race conditions across multiple synchronous navigations.

### 7.4.2.3.4 Non-fetch schemes and external software <sup>§<sup>p10</sup><sub>23</sub></sup>

The input to [attempt to create a non-fetch scheme document<sup>p1024</sup>](#) is the **non-fetch scheme navigation params struct**. It is a lightweight version of [navigation params<sup>p1013</sup>](#) which only carries parameters relevant to the non-[fetch scheme](#) navigation case. It has the following [items](#):

#### **id**

null or a [navigation ID<sup>p1014</sup>](#)

#### **navigable**

the [navigable<sup>p989</sup>](#) experiencing the navigation

#### **URL**

a [URL](#)

#### **target snapshot sandboxing flags**

the [target snapshot params<sup>p1013</sup>](#)'s [sandboxing flags<sup>p1013</sup>](#) present during navigation

#### **source snapshot has transient activation**

a copy of the [source snapshot params<sup>p1012</sup>](#)'s [has transient activation<sup>p1012</sup>](#) boolean present during activation

## initiator origin

an [origin](#)<sup>p898</sup> possibly for use in a user-facing prompt to confirm the invocation of an external software package

### Note

This differs slightly from a [document state](#)<sup>p1005</sup>'s [initiator origin](#)<sup>p1006</sup> in that a [non-fetch scheme navigation params](#)<sup>p1023</sup>'s [initiator origin](#)<sup>p1024</sup> follows redirects up to the last [fetch scheme](#) URL in a redirect chain that ends in a [non-fetch scheme](#) URL.

## navigation timing type

a [NavigationTimingType](#) used for [creating the navigation timing entry](#) for the new [Document](#)<sup>p139</sup>

To **attempt to create a non-fetch scheme document**, given a [non-fetch scheme navigation params](#)<sup>p1023</sup> *navigationParams*:

1. Let *url* be *navigationParams*'s [URL](#)<sup>p1023</sup>.
2. Let *navigable* be *navigationParams*'s [navigable](#)<sup>p1023</sup>.
3. If *url* is to be handled using a mechanism that does not affect *navigable*, e.g., because *url*'s [scheme](#) is handled externally, then:
  1. [Hand-off to external software](#)<sup>p1024</sup> given *url*, *navigable*, *navigationParams*'s [target snapshot sandboxing flags](#)<sup>p1023</sup>, *navigationParams*'s [source snapshot has transient activation](#)<sup>p1023</sup>, and *navigationParams*'s [initiator origin](#)<sup>p1024</sup>.
  2. Return null.
4. Handle *url* by displaying some sort of inline content, e.g., an error message because the specified scheme is not one of the supported protocols, or an inline prompt to allow the user to select a [registered handler](#)<sup>p1174</sup> for the given scheme. Return the result of [displaying the inline content](#)<sup>p1062</sup> given *navigable*, *navigationParams*'s [id](#)<sup>p1023</sup>, and *navigationParams*'s [navigation timing type](#)<sup>p1024</sup>.

### Note

In the case of a registered handler being used, [navigate](#)<sup>p1014</sup> will be invoked with a new URL.

To **hand-off to external software** given a [URL](#) or [response](#) *resource*, a [navigable](#)<sup>p989</sup> *navigable*, a [sandboxing flag set](#)<sup>p914</sup> *sandboxFlags*, a boolean *hasTransientActivation*, and an [origin](#)<sup>p898</sup> *initiatorOrigin* user agents should:

1. If all of the following are true:
  - *navigable* is not a [top-level traversable](#)<sup>p990</sup>;
  - *sandboxFlags* has its [sandboxed custom protocols navigation browsing context flag](#)<sup>p916</sup> set; and
  - *sandboxFlags* has its [sandboxed top-level navigation with user activation browsing context flag](#)<sup>p915</sup> set, or *hasTransientActivation* is false,

then return without invoking the external software package.

### Note

Navigation inside an *iframe* toward external software can be seen by users as a new popup or a new top-level navigation. That's why its is allowed in sandboxed [iframe](#)<sup>p390</sup> only when one of [allow-popups](#)<sup>p916</sup>, [allow-top-navigation](#)<sup>p916</sup>, [allow-top-navigation-by-user-activation](#)<sup>p916</sup>, or [allow-top-navigation-to-custom-protocols](#)<sup>p917</sup> is specified.

2. Perform the appropriate handoff of *resource* while attempting to mitigate the risk that this is an attempt to exploit the target software. For example, user agents could prompt the user to confirm that *initiatorOrigin* is to be allowed to invoke the external software in question. In particular, if *hasTransientActivation* is false, then the user agent should not invoke the external software package without prior user confirmation.

### Example

For example, there could be a vulnerability in the target software's URL handler which a hostile page would attempt to exploit by tricking a user into clicking a link.

#### 7.4.2.4 Preventing navigation §<sup>p10</sup><sub>25</sub>

A couple of scenarios can intervene early in the navigation process and put the whole thing to a halt. This can be especially exciting when multiple [navigables<sup>p989</sup>](#) are navigating at the same time, due to a session history traversal.

A [navigable<sup>p989</sup>](#) *source* is **allowed by sandboxing to navigate** a second [navigable<sup>p989</sup>](#) *target*, given a [source snapshot params<sup>p1012</sup>](#) *sourceSnapshotParams*, if the following steps return true:

1. If *source* is *target*, then return true.
2. If *source* is an ancestor of *target*, then return true.
3. If *target* is an ancestor of *source*, then:
  1. If *target* is not a [top-level traversable<sup>p990</sup>](#), then return true.
  2. If *sourceSnapshotParams*'s [has transient activation<sup>p1012</sup>](#) is true, and *sourceSnapshotParams*'s [sandboxing flags<sup>p1012</sup>](#)'s [sandboxed top-level navigation with user activation browsing context flag<sup>p915</sup>](#) is set, then return false.
  3. If *sourceSnapshotParams*'s [has transient activation<sup>p1012</sup>](#) is false, and *sourceSnapshotParams*'s [sandboxing flags<sup>p1012</sup>](#)'s [sandboxed top-level navigation without user activation browsing context flag<sup>p915</sup>](#) is set, then return false.
  4. Return true.
4. If *target* is a [top-level traversable<sup>p990</sup>](#):
  1. If *source* is the [one permitted sandboxed navigator<sup>p914</sup>](#) of *target*, then return true.
  2. If *sourceSnapshotParams*'s [sandboxing flags<sup>p1012</sup>](#)'s [sandboxed navigation browsing context flag<sup>p914</sup>](#) is set, then return false.
  3. Return true.
5. If *sourceSnapshotParams*'s [sandboxing flags<sup>p1012</sup>](#)'s [sandboxed navigation browsing context flag<sup>p914</sup>](#) is set, then return false.
6. Return true.

To **check if unloading is canceled** for a [list](#) of [navigables<sup>p989</sup>](#) *navigablesThatNeedBeforeUnload*, given an optional [traversable navigable<sup>p990</sup>](#) *traversable*, an optional integer *targetStep*, and an optional [user navigation involvement<sup>p1014</sup>](#)-or-null *userInvolvementForNavigateEvent*, run these steps. They return "canceled-by-beforeunload", "canceled-by-navigate", or "continue".

1. Let *documentsToFireBeforeunload* be the [active document<sup>p989</sup>](#) of each *item* in *navigablesThatNeedBeforeUnload*.
2. Let *unloadPromptShown* be false.
3. Let *finalStatus* be "continue".
4. If *traversable* was given, then:
  1. **Assert:** *targetStep* and *userInvolvementForNavigateEvent* were given.
  2. Let *targetEntry* be the result of [getting the target history entry<sup>p1048</sup>](#) given *traversable* and *targetStep*.
  3. If *targetEntry* is not *traversable*'s [current session history entry<sup>p989</sup>](#), and *targetEntry*'s [document state<sup>p1005</sup>](#)'s [origin<sup>p1006</sup>](#) is the [same<sup>p899</sup>](#) as *traversable*'s [current session history entry<sup>p989</sup>](#)'s [document state<sup>p1005</sup>](#)'s [origin<sup>p1006</sup>](#), then:

#### Note

*In this case, we're going to fire the [navigate<sup>p1472</sup>](#) event for traversable here. Because [under some circumstances<sup>p976</sup>](#) it might be canceled, we need to do this separately from [other traversal navigate events<sup>p1042</sup>](#), which happen later.*

*Additionally, because we want [beforeunload<sup>p1471</sup>](#) events to fire before [navigate<sup>p1472</sup>](#) events, this means we need to fire [beforeunload<sup>p1471</sup>](#) for traversable here (if applicable), instead of doing it as part of the below loop over *documentsToFireBeforeunload*.*

1. **Assert:** *userInvolvementForNavigateEvent* is not null.

2. Let *eventsFired* be false.
  3. Let *needsBeforeunload* be true if *navigablesThatNeedBeforeUnload* [contains](#) *traversable*; otherwise false.
  4. If *needsBeforeunload* is true, then [remove](#) *traversable*'s [active document](#)<sup>p989</sup> from *documentsToFireBeforeunload*.
  5. [Queue a global task](#)<sup>p1125</sup> on the [navigation and traversal task source](#)<sup>p1134</sup> given *traversable*'s [active window](#)<sup>p989</sup> to perform the following steps:
    1. If *needsBeforeunload* is true, then:
      1. Let (*unloadPromptShownForThisDocument*, *unloadPromptCanceledByThisDocument*) be the result of running the [steps to fire beforeunload](#)<sup>p1026</sup> given *traversable*'s [active document](#)<sup>p989</sup> and false.
      2. If *unloadPromptShownForThisDocument* is true, then set *unloadPromptShown* to true.
      3. If *unloadPromptCanceledByThisDocument* is true, then set *finalStatus* to "canceled-by-beforeunload".
    2. If *finalStatus* is "canceled-by-beforeunload", then abort these steps.
    3. Let *navigation* be *traversable*'s [active window](#)<sup>p989</sup>'s [navigation API](#)<sup>p952</sup>.
    4. Let *navigateEventResult* be the result of [firing a traverse navigate event](#)<sup>p974</sup> at *navigation* given *targetEntry* and *userInvolvementForNavigateEvent*.
    5. If *navigateEventResult* is false, then set *finalStatus* to "canceled-by-navigate".
    6. Set *eventsFired* to true.
  6. Wait until *eventsFired* is true.
  7. If *finalStatus* is not "continue", then return *finalStatus*.
5. Let *totalTasks* be the [size](#) of *documentsThatNeedBeforeunload*.
  6. Let *completedTasks* be 0.
  7. [For each](#) *document* of *documents*, [queue a global task](#)<sup>p1125</sup> on the [navigation and traversal task source](#)<sup>p1134</sup> given *document*'s [relevant global object](#)<sup>p1083</sup> to run the steps:
    1. Let (*unloadPromptShownForThisDocument*, *unloadPromptCanceledByThisDocument*) be the result of running the [steps to fire beforeunload](#)<sup>p1026</sup> given *document* and *unloadPromptShown*.
    2. If *unloadPromptShownForThisDocument* is true, then set *unloadPromptShown* to true.
    3. If *unloadPromptCanceledByThisDocument* is true, then set *finalStatus* to "canceled-by-beforeunload".
    4. Increment *completedTasks*.
  8. Wait for *completedTasks* to be *totalTasks*.
  9. Return *finalStatus*.

The **steps to fire beforeunload** given a [Document](#)<sup>p130</sup> *document* and a boolean *unloadPromptShown* are:

1. Let *unloadPromptCanceled* be false.
2. Increase the *document*'s [unload counter](#)<sup>p1064</sup> by 1.
3. Increase *document*'s [relevant agent](#)<sup>p1073</sup>'s [event loop](#)<sup>p1123</sup>'s [termination nesting level](#)<sup>p1064</sup> by 1.
4. Let *eventFiringResult* be the result of [firing an event](#) named [beforeunload](#)<sup>p1471</sup> at *document*'s [relevant global object](#)<sup>p1083</sup>, using [BeforeUnloadEvent](#)<sup>p983</sup>, with the [cancelable](#) attribute initialized to true.
5. Decrease *document*'s [relevant agent](#)<sup>p1073</sup>'s [event loop](#)<sup>p1123</sup>'s [termination nesting level](#)<sup>p1064</sup> by 1.
6. If all of the following are true:

- `unloadPromptShown` is false;
- `document`'s [active sandboxing flag set](#)<sup>p917</sup> does not have its [sandboxed modals flag](#)<sup>p915</sup> set;
- `document`'s [relevant global object](#)<sup>p1083</sup> has [sticky activation](#)<sup>p830</sup>;
- `eventFiringResult` is false, or the [returnValue](#)<sup>p983</sup> attribute of `event` is not the empty string; and
- showing an unload prompt is unlikely to be annoying, deceptive, or pointless,

then:

1. Set `unloadPromptShown` to true.
  2. Let `userPromptHandler` be the result of [WebDriver BiDi user prompt opened](#) with `document`'s [relevant global object](#)<sup>p1083</sup>, `"beforeunload"`, and `""`.
  3. If `userPromptHandler` is `"dismiss"`, then set `unloadPromptCanceled` to true.
  4. If `userPromptHandler` is `"none"`, then:
    - Ask the user to confirm that they wish to unload the document, and [pause](#)<sup>p1133</sup> while waiting for the user's response.
- Note**

*The message shown to the user is not customizable, but instead determined by the user agent. In particular, the actual value of the [returnValue](#)<sup>p983</sup> attribute is ignored.*
- If the user did not confirm the page navigation, then set `unloadPromptCanceled` to true.
  5. Invoke [WebDriver BiDi user prompt closed](#) with `document`'s [relevant global object](#)<sup>p1083</sup>, `"beforeunload"`, and true if `unloadPromptCanceled` is false or false otherwise.
  7. Decrease `document`'s [unload counter](#)<sup>p1064</sup> by 1.
  8. Return (`unloadPromptShown`, `unloadPromptCanceled`).

#### 7.4.2.5 Aborting navigation §<sup>p10</sup><sub>27</sub>

Each [navigable](#)<sup>p989</sup> has an **ongoing navigation**, which is a [navigation ID](#)<sup>p1014</sup>, `"traversal"`, or null, initially null. It is used to track navigation aborting and to prevent any navigations from taking place during [traversal](#)<sup>p1040</sup>.

To **set the ongoing navigation** for a [navigable](#)<sup>p989</sup> `navigable` to `newValue`:

1. If `navigable`'s [ongoing navigation](#)<sup>p1027</sup> is equal to `newValue`, then return.
2. [Inform the navigation API about aborting navigation](#)<sup>p967</sup> given `navigable`.
3. Set `navigable`'s [ongoing navigation](#)<sup>p1027</sup> to `newValue`.

#### 7.4.3 Reloading and traversing §<sup>p10</sup><sub>27</sub>

To **reload** a [navigable](#)<sup>p989</sup> `navigable` given an optional [serialized state](#)<sup>p1006</sup>-or-null **navigationAPIState** (default null) and an optional [user navigation involvement](#)<sup>p1014</sup> **userInvolvement** (default `"none"`<sup>p1014</sup>):

1. If `userInvolvement` is not `"browser UI"`<sup>p1014</sup>, then:
  1. Let `navigation` be `navigable`'s [active window](#)<sup>p989</sup>'s [navigation API](#)<sup>p952</sup>.
  2. Let `destinationNavigationAPIState` be `navigable`'s [active session history entry](#)<sup>p989</sup>'s [navigation API state](#)<sup>p1005</sup>.
  3. If `navigationAPIState` is not null, then set `destinationNavigationAPIState` to `navigationAPIState`.
  4. Let `continue` be the result of [firing a push/replace/reload navigate event](#)<sup>p974</sup> at `navigation` with [navigationType](#)<sup>p974</sup> set to `"reload"`<sup>p954</sup>, [isSameDocument](#)<sup>p974</sup> set to false, [userInvolvement](#)<sup>p974</sup> set to `userInvolvement`,

[destinationURL](#)<sup>p974</sup> set to [navigable](#)'s [active session history entry](#)<sup>p989</sup>'s [URL](#)<sup>p1005</sup>, and [navigationAPIState](#)<sup>p975</sup> set to [destinationNavigationAPIState](#).

5. If *continue* is false, then return.
2. Set [navigable](#)'s [active session history entry](#)<sup>p989</sup>'s [document state](#)<sup>p1005</sup>'s [reload pending](#)<sup>p1007</sup> to true.
3. Let *traversable* be [navigable](#)'s [traversable navigable](#)<sup>p990</sup>.
4. [Append the following session history traversal steps](#)<sup>p1008</sup> to *traversable*:
  1. [Apply the reload history step](#)<sup>p1040</sup> to *traversable*.

To **traverse the history by a delta** given a [traversable navigable](#)<sup>p990</sup> *traversable*, an integer *delta*, and an optional [Document](#)<sup>p130</sup> *sourceDocument*:

1. Let *sourceSnapshotParams* and *initiatorToCheck* be null.
2. Let *userInvolvement* be "[browser UI](#)<sup>p1014</sup>".
3. If *sourceDocument* is given, then:
  1. Set *sourceSnapshotParams* to the result of [snapshotting source snapshot params](#)<sup>p1012</sup> given *sourceDocument*.
  2. Set *initiatorToCheck* to *sourceDocument*'s [node navigable](#)<sup>p989</sup>.
  3. Set *userInvolvement* to "[none](#)<sup>p1014</sup>".
4. [Append the following session history traversal steps](#)<sup>p1008</sup> to *traversable*:
  1. Let *allSteps* be the result of [getting all used history steps](#)<sup>p1011</sup> for *traversable*.
  2. Let *currentStepIndex* be the index of *traversable*'s [current session history step](#)<sup>p990</sup> within *allSteps*.
  3. Let *targetStepIndex* be *currentStepIndex* plus *delta*.
  4. If *allSteps*[*targetStepIndex*] does not [exist](#), then abort these steps.
  5. [Apply the traverse history step](#)<sup>p1040</sup> *allSteps*[*targetStepIndex*] to *traversable*, given *sourceSnapshotParams*, *initiatorToCheck*, and *userInvolvement*.

#### 7.4.4 Non-fragment synchronous "navigations" <sup>§<sup>p10</sup><sub>28</sub></sup>

Apart from the [navigate](#)<sup>p1014</sup> algorithm, [session history entries](#)<sup>p1005</sup> can be pushed or replaced via one more mechanism, the [URL and history update steps](#)<sup>p1028</sup>. The most well-known callers of these steps are the [history.replaceState\(\)](#)<sup>p946</sup> and [history.pushState\(\)](#)<sup>p946</sup> APIs, but various other parts of the standard also need to perform updates to the [active history entry](#)<sup>p989</sup>, and they use these steps to do so.

The **URL and history update steps**, given a [Document](#)<sup>p130</sup> *document*, a [URL](#) *newURL*, an optional [serialized state](#)<sup>p1006</sup>-or-null *serializedData* (default null), and an optional [history handling behavior](#)<sup>p1014</sup> *historyHandling* (default "[replace](#)<sup>p1014</sup>"), are:

1. Let *navigable* be *document*'s [node navigable](#)<sup>p989</sup>.
2. Let *activeEntry* be *navigable*'s [active session history entry](#)<sup>p989</sup>.
3. Let *newEntry* be a new [session history entry](#)<sup>p1005</sup>, with
  - [URL](#)<sup>p1005</sup>  
*newURL*
  - [serialized state](#)<sup>p1005</sup>  
if *serializedData* is not null, *serializedData*; otherwise *activeEntry*'s [classic history API state](#)<sup>p1005</sup>
  - [document state](#)<sup>p1005</sup>  
*activeEntry*'s [document state](#)<sup>p1005</sup>
  - [scroll restoration mode](#)<sup>p1005</sup>  
*activeEntry*'s [scroll restoration mode](#)<sup>p1005</sup>
  - [persisted user state](#)<sup>p1005</sup>  
*activeEntry*'s [persisted user state](#)<sup>p1005</sup>

4. If document's [is initial about:blank](#)<sup>p131</sup> is true, then set `historyHandling` to "[replace](#)<sup>p1014</sup>".

#### Note

This means that `pushState()`<sup>p946</sup> on an [initial about:blank](#)<sup>p131</sup> [Document](#)<sup>p130</sup> behaves as a `replaceState()`<sup>p946</sup> call.

5. Let `entryToReplace` be `activeEntry` if `historyHandling` is "[replace](#)<sup>p1014</sup>", otherwise null.
6. If `historyHandling` is "[push](#)<sup>p1014</sup>", then:

1. Increment document's [history object](#)<sup>p945</sup>'s [index](#)<sup>p946</sup>.
2. Set document's [history object](#)<sup>p945</sup>'s [length](#)<sup>p946</sup> to its [index](#)<sup>p946</sup> + 1.

#### Note

These are temporary best-guess values for immediate synchronous access.

7. If `serializedData` is not null, then [restore the history object state](#)<sup>p1051</sup> given `document` and `newEntry`.
8. Set document's [URL](#) to `newURL`.

#### Note

Since this is neither a [navigation](#)<sup>p1014</sup> nor a [history traversal](#)<sup>p1028</sup>, it does not cause a [hashchange](#)<sup>p1471</sup> event to be fired.

9. Set document's [latest entry](#)<sup>p1008</sup> to `newEntry`.
10. Set `navigable`'s [active session history entry](#)<sup>p989</sup> to `newEntry`.
11. [Update the navigation API entries for a same-document navigation](#)<sup>p955</sup> given document's [relevant global object](#)<sup>p1083</sup>'s [navigation API](#)<sup>p952</sup>, `newEntry`, and `historyHandling`.
12. Let `traversable` be `navigable`'s [traversable navigable](#)<sup>p990</sup>.
13. [Append the following session history synchronous navigation steps](#)<sup>p1008</sup> involving `navigable` to `traversable`:
  1. [Finalize a same-document navigation](#)<sup>p1023</sup> given `traversable`, `navigable`, `newEntry`, `entryToReplace`, and `historyHandling`.
  2. Invoke [WebDriver BiDi history updated](#) with `navigable`.

#### Note

Although both [fragment navigation](#)<sup>p1021</sup> and the [URL and history update steps](#)<sup>p1028</sup> perform synchronous history updates, only fragment navigation contains a synchronous call to [update document for history step application](#)<sup>p1049</sup>. The [URL and history update steps](#)<sup>p1028</sup> instead perform a few select updates inside the above algorithm, omitting others. This is somewhat of an unfortunate historical accident, and generally leads to [web-developer sadness](#) about the inconsistency. For example, this means that [popstate](#)<sup>p1472</sup> events fire for fragment navigations, but not for `history.pushState()`<sup>p946</sup> calls.

## 7.4.5 Populating a session history entry <sup>§ p1029</sup>

As explained in [the overview](#)<sup>p1004</sup>, both [navigation](#)<sup>p1012</sup> and [traversal](#)<sup>p1027</sup> involve creating a [session history entry](#)<sup>p1005</sup> and then attempting to populate its [document](#)<sup>p1005</sup> member, so that it can be presented inside the [navigable](#)<sup>p989</sup>.

This involves either: using [an already-given response](#)<sup>p1017</sup>; using the [srcdoc resource](#)<sup>p1007</sup> stored in the [session history entry](#)<sup>p1005</sup>; or [fetching](#)<sup>p1033</sup>. The process has several failure modes, which can either result in doing nothing (leaving the [navigable](#)<sup>p989</sup> on its currently-[active](#)<sup>p989</sup> [Document](#)<sup>p130</sup>) or can result in populating the [session history entry](#)<sup>p1005</sup> with an [error document](#)<sup>p1062</sup>.

To **attempt to populate the history entry's document** for a [session history entry](#)<sup>p1005</sup> entry, given a [navigable](#)<sup>p989</sup> `navigable`, a [NavigationTimingType](#) `navTimingType`, a [source snapshot params](#)<sup>p1012</sup> `sourceSnapshotParams`, a [target snapshot params](#)<sup>p1013</sup> `targetSnapshotParams`, an optional [navigation ID](#)<sup>p1014</sup>-or-null `navigationId` (default null), an optional [navigation params](#)<sup>p1013</sup>-or-null `navigationParams` (default null), an optional string `cspNavigationType` (default "other"), an optional boolean **allowPOST** (default false), and optional algorithm steps **completionSteps** (default an empty algorithm):

1. **Assert**: this is running [in parallel](#)<sup>p43</sup>.

2. **Assert**: if *navigationParams* is non-null, then *navigationParams*'s [response](#)<sup>p1013</sup> is non-null.
3. Let *currentBrowsingContext* be *navigable*'s [active browsing context](#)<sup>p989</sup>.
4. Let *documentResource* be *entry*'s [document state](#)<sup>p1005</sup>'s [resource](#)<sup>p1007</sup>.
5. If *navigationParams* is null, then:
  1. If *documentResource* is a string, then set *navigationParams* to the result of [creating navigation params from a srcdoc resource](#)<sup>p1032</sup> given *entry*, *navigable*, *targetSnapshotParams*, *navigationId*, and *navTimingType*.
  2. Otherwise, if all of the following are true:
    - *entry*'s [URL](#)<sup>p1005</sup>'s [scheme](#) is a [fetch scheme](#); and
    - *documentResource* is null, or *allowPOST* is true and *documentResource*'s [request body](#)<sup>p1007</sup> is not failure,
 then set *navigationParams* to the result of [creating navigation params by fetching](#)<sup>p1033</sup> given *entry*, *navigable*, *sourceSnapshotParams*, *targetSnapshotParams*, *cspNavigationType*, *navigationId*, and *navTimingType*.
  3. Otherwise, if *entry*'s [URL](#)<sup>p1005</sup>'s [scheme](#) is not a [fetch scheme](#), then set *navigationParams* to a new [non-fetch scheme navigation params](#)<sup>p1023</sup>, with
 

[id](#)<sup>p1023</sup>  
*navigationId*  
[navigable](#)<sup>p1023</sup>  
*navigable*  
[URL](#)<sup>p1023</sup>  
*entry*'s [URL](#)<sup>p1005</sup>  
[target snapshot sandboxing flags](#)<sup>p1023</sup>  
*targetSnapshotParams*'s [sandboxing flags](#)<sup>p1013</sup>  
[source snapshot has transient activation](#)<sup>p1023</sup>  
*sourceSnapshotParams*'s [has transient activation](#)<sup>p1012</sup>  
[initiator origin](#)<sup>p1024</sup>  
*entry*'s [document state](#)<sup>p1005</sup>'s [initiator origin](#)<sup>p1006</sup>  
[navigation timing type](#)<sup>p1024</sup>  
*navTimingType*
6. [Queue a global task](#)<sup>p1125</sup> on the [navigation and traversal task source](#)<sup>p1134</sup>, given *navigable*'s [active window](#)<sup>p998</sup>, to run these steps:
  1. If *navigable*'s [ongoing navigation](#)<sup>p1027</sup> no longer equals *navigationId*, then run *completionSteps* and abort these steps.
  2. Let *saveExtraDocumentState* be true.

#### Note

Usually, in the cases where we end up populating *entry*'s [document state](#)<sup>p1005</sup>'s [document](#)<sup>p1006</sup>, we then want to save some of the state from that [Document](#)<sup>p130</sup> into *entry*. This ensures that if there are future traversals to *entry* where its [document](#)<sup>p1006</sup> has been destroyed<sup>p1006</sup>, we can use that state when creating a new [Document](#)<sup>p130</sup>.

However, in some specific cases, saving the state would be unhelpful. For those, we set *saveExtraDocumentState* to false later in this algorithm.

3. If *navigationParams* is a [non-fetch scheme navigation params](#)<sup>p1023</sup>, then:
    1. Set *entry*'s [document state](#)<sup>p1005</sup>'s [document](#)<sup>p1006</sup> to the result of running [attempt to create a non-fetch scheme document](#)<sup>p1024</sup> given *navigationParams*.

#### Note

This can result in setting *entry*'s [document state](#)<sup>p1005</sup>'s [document](#)<sup>p1006</sup> to null, e.g., when [handing-off to external software](#)<sup>p1024</sup>.

  - 2. Set *saveExtraDocumentState* to false.
4. Otherwise, if any of the following are true:

- `navigationParams` is null;
- the result of [should navigation response to navigation request of type in target be blocked by Content Security Policy?](#) given `navigationParams`'s [request](#)<sup>p1013</sup>, `navigationParams`'s [response](#)<sup>p1013</sup>, `navigationParams`'s [policy container](#)<sup>p1013</sup>'s [CSP list](#)<sup>p917</sup>, `cspNavigationType`, and `navigable` is "Blocked";
- `navigationParams`'s [reserved environment](#)<sup>p1013</sup> is non-null and the result of [checking a navigation response's adherence to its embedder policy](#)<sup>p913</sup> given `navigationParams`'s [response](#)<sup>p1013</sup>, `navigable`, and `navigationParams`'s [policy container](#)<sup>p1013</sup>'s [embedder policy](#)<sup>p917</sup> is false; or
- the result of [checking a navigation response's adherence to `X-Frame-Options`](#)<sup>p1068</sup> given `navigationParams`'s [response](#)<sup>p1013</sup>, `navigable`, `navigationParams`'s [policy container](#)<sup>p1013</sup>'s [CSP list](#)<sup>p917</sup>, and `navigationParams`'s [origin](#)<sup>p1013</sup> is false,

then:

1. Set entry's [document state](#)<sup>p1005</sup>'s [document](#)<sup>p1006</sup> to the result of [creating a document for inline content that doesn't have a DOM](#)<sup>p1062</sup>, given `navigable`, null, and `navTimingType`. The inline content should indicate to the user the sort of error that occurred.
2. [Make document unsalvageable](#)<sup>p1052</sup> given entry's [document state](#)<sup>p1005</sup>'s [document](#)<sup>p1006</sup> and "navigation-failure<sup>p985</sup>".
3. Set `saveExtraDocumentState` to false.
4. If `navigationParams` is not null, then:
  1. Run the [environment discarding steps](#)<sup>p1076</sup> for `navigationParams`'s [reserved environment](#)<sup>p1013</sup>.
  2. Invoke [WebDriver BiDi navigation failed](#) with `currentBrowsingContext` and a new [WebDriver BiDi navigation status](#) whose `id` is `navigationId`, `status` is "canceled", and `url` is `navigationParams`'s [response](#)<sup>p1013</sup>'s [URL](#).
5. Otherwise, if `navigationParams`'s [response](#)<sup>p1013</sup> has a ``Content-Disposition`` header specifying the attachment disposition type, then:
  1. Let `sourceAllowsDownloading` be `sourceSnapshotParams`'s [allows downloading](#)<sup>p1012</sup>.
  2. Let `targetAllowsDownloading` be false if `navigationParams`'s [final sandboxing flag set](#)<sup>p1013</sup> has the [sandboxed downloads browsing context flag](#)<sup>p916</sup> set; otherwise true.
  3. Let `uaAllowsDownloading` be true.
  4. Optionally, the user agent may set `uaAllowsDownloading` to false, if it believes doing so would safeguard the user from a potentially hostile download.
  5. If `sourceAllowsDownloading`, `targetAllowsDownloading`, and `uaAllowsDownloading` are true, then:
    1. Handle `navigationParams`'s [response](#)<sup>p1013</sup> [as a download](#)<sup>p311</sup>.
    2. Invoke [WebDriver BiDi download started](#) with `currentBrowsingContext` and a new [WebDriver BiDi navigation status](#) whose `id` is `navigationId`, `status` is "complete", and `url` is `navigationParams`'s [response](#)<sup>p1013</sup>'s [URL](#).

#### Note

*This branch leaves entry's [document state](#)<sup>p1005</sup>'s [document](#)<sup>p1006</sup> as null.*

6. Otherwise, if `navigationParams`'s [response](#)<sup>p1013</sup>'s `status` is not 204 and is not 205, then set entry's [document state](#)<sup>p1005</sup>'s [document](#)<sup>p1006</sup> to the result of [loading a document](#)<sup>p1039</sup> given `navigationParams`, `sourceSnapshotParams`, and entry's [document state](#)<sup>p1005</sup>'s [initiator origin](#)<sup>p1006</sup>.

#### Note

*This can result in setting entry's [document state](#)<sup>p1005</sup>'s [document](#)<sup>p1006</sup> to null, e.g., when [handing-off to external software](#)<sup>p1024</sup>.*

7. If entry's [document state](#)<sup>p1005</sup>'s [document](#)<sup>p1006</sup> is not null, then:
  1. Set entry's [document state](#)<sup>p1005</sup>'s [ever populated](#)<sup>p1007</sup> to true.

2. If *saveExtraDocumentState* is true:

1. Let *document* be entry's [document state](#)<sup>p1005</sup>'s [document](#)<sup>p1006</sup>.
  2. Set entry's [document state](#)<sup>p1005</sup>'s [origin](#)<sup>p1006</sup> to *document*'s [origin](#).
  3. If *document*'s [URL requires storing the policy container in history](#)<sup>p918</sup>, then:
    1. **Assert:** *navigationParams* is a [navigation params](#)<sup>p1013</sup> (i.e., neither null nor a [non-fetch scheme navigation params](#)<sup>p1023</sup>).
    2. Set entry's [document state](#)<sup>p1005</sup>'s [history policy container](#)<sup>p1006</sup> to *navigationParams*'s [policy container](#)<sup>p1013</sup>.
3. If entry's [document state](#)<sup>p1005</sup>'s [request referrer](#)<sup>p1006</sup> is "client", and *navigationParams* is a [navigation params](#)<sup>p1013</sup> (i.e., neither null nor a [non-fetch scheme navigation params](#)<sup>p1023</sup>), then:
1. **Assert:** *navigationParams*'s [request](#)<sup>p1013</sup> is not null.
  2. Set entry's [document state](#)<sup>p1005</sup>'s [request referrer](#)<sup>p1006</sup> to *navigationParams*'s [request](#)<sup>p1013</sup>'s [referrer](#).

8. Run *completionSteps*.

To **create navigation params from a srcdoc resource** given a [session history entry](#)<sup>p1005</sup> *entry*, a [navigable](#)<sup>p989</sup> *navigable*, a [target snapshot params](#)<sup>p1013</sup> *targetSnapshotParams*, a [navigation ID](#)<sup>p1014</sup>-or-null *navigationId*, and a [NavigationTimingType](#) *navTimingType*:

1. Let *documentResource* be entry's [document state](#)<sup>p1005</sup>'s [resource](#)<sup>p1007</sup>.
2. Let *response* be a new [response](#) with
  - [URL](#)  
[about:srcdoc](#)<sup>p96</sup>
  - [header list](#)  
« ([Content-Type](#)<sup>p98</sup>, `text/html`) »
  - [body](#)  
the [UTF-8 encoding](#) of *documentResource*, [as a body](#)
3. Let *responseOrigin* be the result of [determining the origin](#)<sup>p1001</sup> given *response*'s [URL](#), *targetSnapshotParams*'s [sandboxing flags](#)<sup>p1013</sup>, and entry's [document state](#)<sup>p1005</sup>'s [origin](#)<sup>p1006</sup>.
4. Let *coop* be a new [opener policy](#)<sup>p904</sup>.
5. Let *coopEnforcementResult* be a new [opener policy enforcement result](#)<sup>p906</sup> with
  - [url](#)<sup>p906</sup>  
*response*'s [URL](#)
  - [origin](#)<sup>p906</sup>  
*responseOrigin*
  - [opener policy](#)<sup>p906</sup>  
*coop*
6. Let *policyContainer* be the result of [determining navigation params policy container](#)<sup>p918</sup> given *response*'s [URL](#), entry's [document state](#)<sup>p1005</sup>'s [history policy container](#)<sup>p1006</sup>, null, *navigable*'s [container document](#)<sup>p992</sup>'s [policy container](#)<sup>p131</sup>, and null.
7. Return a new [navigation params](#)<sup>p1013</sup>, with
  - [id](#)<sup>p1013</sup>  
*navigationId*
  - [navigable](#)<sup>p1013</sup>  
*navigable*
  - [request](#)<sup>p1013</sup>  
null
  - [response](#)<sup>p1013</sup>  
*response*
  - [fetch controller](#)<sup>p1013</sup>  
null
  - [commit early hints](#)<sup>p1013</sup>  
null

**COOP enforcement result**<sup>p1013</sup>*coopEnforcementResult***reserved environment**<sup>p1013</sup>

null

**origin**<sup>p1013</sup>*responseOrigin***policy container**<sup>p1013</sup>*policyContainer***final sandboxing flag set**<sup>p1013</sup>*targetSnapshotParams*'s *sandboxing flags*<sup>p1013</sup>**opener policy**<sup>p1013</sup>*coop***navigation timing type**<sup>p1013</sup>*navTimingType***about base URL**<sup>p1013</sup>*entry*'s *document state*<sup>p1005</sup>'s *about base URL*<sup>p1007</sup>

To **create navigation params by fetching** given a *session history entry*<sup>p1005</sup> *entry*, a *navigable*<sup>p989</sup> *navigable*, a *source snapshot params*<sup>p1012</sup> *sourceSnapshotParams*, a *target snapshot params*<sup>p1013</sup> *targetSnapshotParams*, a string *cspNavigationType*, a *navigation ID*<sup>p1014</sup> *navigationId*-or-null *navigationId*, and a *NavigationTimingType* *navTimingType*, perform the following steps. They return a *navigation params*<sup>p1013</sup>, a *non-fetch scheme navigation params*<sup>p1023</sup>, or null.

**Note**

*This algorithm mutates entry.*

1. **Assert**: this is running *in parallel*<sup>p43</sup>.
2. Let *documentResource* be *entry*'s *document state*<sup>p1005</sup>'s *resource*<sup>p1007</sup>.
3. Let *request* be a new *request*, with
  - url**  
*entry*'s *URL*<sup>p1005</sup>
  - client**  
*sourceSnapshotParams*'s *fetch client*<sup>p1012</sup>
  - destination**  
"document"
  - credentials mode**  
"include"
  - use-URL-credentials flag**  
set
  - redirect mode**  
"manual"
  - replaces client id**  
*navigable*'s *active document*<sup>p989</sup>'s *relevant settings object*<sup>p1083</sup>'s *id*<sup>p1075</sup>
  - mode**  
"navigate"
  - referrer**  
*entry*'s *document state*<sup>p1005</sup>'s *request referrer*<sup>p1006</sup>
  - referrer policy**  
*entry*'s *document state*<sup>p1005</sup>'s *request referrer policy*<sup>p1006</sup>
4. If *documentResource* is a *POST resource*<sup>p1007</sup>, then:
  1. Set *request*'s *method* to `POST`.
  2. Set *request*'s *body* to *documentResource*'s *request body*<sup>p1007</sup>.
  3. Set `Content-Type` to *documentResource*'s *request content-type*<sup>p1007</sup> in *request*'s *header list*.
5. If *entry*'s *document state*<sup>p1005</sup>'s *reload pending*<sup>p1007</sup> is true, then set *request*'s *reload-navigation flag*.
6. Otherwise, if *entry*'s *document state*<sup>p1005</sup>'s *ever populated*<sup>p1007</sup> is true, then set *request*'s *history-navigation flag*.
7. If *sourceSnapshotParams*'s *has transient activation*<sup>p1012</sup> is true, then set *request*'s *user-activation* to true.

8. If *navigable*'s [container](#)<sup>p991</sup> is non-null:
  1. If the *navigable*'s [container](#)<sup>p991</sup> has a [browsing context scope origin](#)<sup>p1038</sup>, then set *request*'s [origin](#) to that [browsing context scope origin](#)<sup>p1038</sup>.
  2. Set *request*'s [destination](#) to *navigable*'s [container](#)<sup>p991</sup>'s [local name](#).
  3. If *sourceSnapshotParams*'s [fetch client](#)<sup>p1012</sup> is *navigable*'s [container document](#)<sup>p992</sup>'s [relevant settings object](#)<sup>p1083</sup>, then set *request*'s [initiator type](#) to *navigable*'s [container](#)<sup>p991</sup>'s [local name](#).

**Note**

*This ensure that only container-initiated navigations are reported to resource timing.*

9. Let *response* be null.
10. Let *responseOrigin* be null.
11. Let *fetchController* be null.
12. Let *coopEnforcementResult* be a new [opener policy enforcement result](#)<sup>p906</sup>, with
  - [url](#)<sup>p906</sup> *navigable*'s [active document](#)<sup>p989</sup>'s [URL](#)
  - [origin](#)<sup>p906</sup> *navigable*'s [active document](#)<sup>p989</sup>'s [origin](#)
  - [opener policy](#)<sup>p906</sup> *navigable*'s [active document](#)<sup>p989</sup>'s [opener policy](#)<sup>p131</sup>
  - [current context is navigation source](#)<sup>p906</sup> true if *navigable*'s [active document](#)<sup>p989</sup>'s [origin](#) is [same origin](#)<sup>p899</sup> with entry's [document state](#)<sup>p1005</sup>'s [initiator origin](#)<sup>p1006</sup> otherwise false
13. Let *finalSandboxFlags* be an empty [sandboxing flag set](#)<sup>p914</sup>.
14. Let *responsePolicyContainer* be null.
15. Let *responseCOOP* be a new [opener policy](#)<sup>p904</sup>.
16. Let *locationURL* be null.
17. Let *currentURL* be *request*'s [current URL](#).
18. Let *commitEarlyHints* be null.
19. While true:
  1. If *request*'s [reserved client](#) is not null and *currentURL*'s [origin](#) is not the [same](#)<sup>p899</sup> as *request*'s [reserved client](#)'s [creation URL](#)<sup>p1075</sup>'s [origin](#), then:
    1. Run the [environment discarding steps](#)<sup>p1076</sup> for *request*'s [reserved client](#).
    2. Set *request*'s [reserved client](#) to null.
    3. Set *commitEarlyHints* to null.

**Note**

*Preloaded links from [early hint headers](#)<sup>p187</sup> remain in the preload cache after a [same origin](#)<sup>p899</sup> redirect, but get discarded when the redirect is cross-origin.*

2. If *request*'s [reserved client](#) is null, then:
  1. Let *topLevelCreationURL* be *currentURL*.
  2. Let *topLevelOrigin* be null.
  3. If *navigable* is not a [top-level traversable](#)<sup>p990</sup>, then:
    1. Let *parentEnvironment* be *navigable*'s [parent](#)<sup>p989</sup>'s [active document](#)<sup>p989</sup>'s [relevant settings object](#)<sup>p1083</sup>.
    2. Set *topLevelCreationURL* to *parentEnvironment*'s [top-level creation URL](#)<sup>p1075</sup>.

3. Set `topLevelOrigin` to `parentEnvironment`'s [top-level origin](#)<sup>p1076</sup>.

4. Set `request`'s [reserved client](#) to a new [environment](#)<sup>p1075</sup> whose [id](#)<sup>p1075</sup> is a unique opaque string, [target browsing context](#)<sup>p1076</sup> is `navigable`'s [active browsing context](#)<sup>p989</sup>, [creation URL](#)<sup>p1075</sup> is `currentURL`, [top-level creation URL](#)<sup>p1075</sup> is `topLevelCreationURL`, and [top-level origin](#)<sup>p1076</sup> is `topLevelOrigin`.

**Note**

The created environment's [active service worker](#)<sup>p1076</sup> is set in the [Handle Fetch](#) algorithm during the fetch if the request URL matches a service worker registration. [\[SW\]](#)<sup>p1482</sup>

3. If the result of [should navigation request of type be blocked by Content Security Policy?](#) given `request` and `cspNavigationType` is "Blocked", then set `response` to a [network error](#) and [break](#). [\[CSP\]](#)<sup>p1476</sup>
4. Set `response` to null.
5. If `fetchController` is null, then set `fetchController` to the result of [fetching](#) `request`, with [processEarlyHintsResponse](#) set to `processEarlyHintsResponse` as defined below, [processResponse](#) set to `processResponse` as defined below, and [useParallelQueue](#) set to true.

Let `processEarlyHintsResponse` be the following algorithm given a [response](#) `earlyResponse`:

1. If `commitEarlyHints` is null, then set `commitEarlyHints` to the result of [processing early hint headers](#)<sup>p188</sup> given `earlyResponse` and `request`'s [reserved client](#).

Let `processResponse` be the following algorithm given a [response](#) `fetchedResponse`:

1. Set `response` to `fetchedResponse`.
6. Otherwise, [process the next manual redirect](#) for `fetchController`.

**Note**

This will result in calling the [processResponse](#) we supplied above, during our first iteration through the loop, and thus setting `response`.

**Note**

Navigation handles redirects manually as navigation is the only place in the web platform that cares for redirects to [mailto:](#) URLs and such.

7. Wait until either `response` is non-null, or `navigable`'s [ongoing navigation](#)<sup>p1027</sup> changes to no longer equal `navigationId`.

If the latter condition occurs, then [abort](#) `fetchController`, and return.

Otherwise, proceed onward.

8. If `request`'s [body](#) is null, then set `entry`'s [document state](#)<sup>p1005</sup>'s [resource](#)<sup>p1007</sup> to null.

**Note**

Fetch unsets the [body](#) for particular redirects.

9. Set `responsePolicyContainer` to the result of [creating a policy container from a fetch response](#)<sup>p918</sup> given `response` and `request`'s [reserved client](#).
10. Set `finalSandboxFlags` to the [union](#) of `targetSnapshotParams`'s [sandboxing flags](#)<sup>p1013</sup> and `responsePolicyContainer`'s [CSP list](#)<sup>p917</sup>'s [CSP-derived sandboxing flags](#)<sup>p917</sup>.
11. Set `responseOrigin` to the result of [determining the origin](#)<sup>p1001</sup> given `response`'s [URL](#), `finalSandboxFlags`, and `entry`'s [document state](#)<sup>p1005</sup>'s [initiator origin](#)<sup>p1006</sup>.

**Note**

If `response` is a redirect, then `response`'s [URL](#) will be the URL that led to the redirect to `response`'s [location URL](#); it will not be the [location URL](#) itself.

12. If `navigable` is a [top-level traversable](#)<sup>p990</sup>, then:
1. Set `responseCOOP` to the result of [obtaining an opener policy](#)<sup>p904</sup> given `response` and `request`'s [reserved](#)

client.

- Set `coopEnforcementResult` to the result of [enforcing the response's opener policy](#)<sup>p906</sup> given `navigable's active browsing context`<sup>p989</sup>, `response's URL`, `responseOrigin`, `responseCOOP`, `coopEnforcementResult` and `request's referrer`.
- If `finalSandboxFlags` is not empty and `responseCOOP's value`<sup>p904</sup> is not "[unsafe-none](#)"<sup>p983</sup>, then set `response` to an appropriate [network error](#) and `break`.

**Note**

*This results in a network error as one cannot simultaneously provide a clean slate to a response using opener policy and sandbox the result of navigating to that response.*

- If `response` is not a [network error](#), `navigable` is a [child navigable](#)<sup>p992</sup>, and the result of performing a [cross-origin resource policy check](#) with `navigable's container document`<sup>p992</sup>'s `origin`, `navigable's container document`<sup>p992</sup>'s [relevant settings object](#)<sup>p1083</sup>, `request's destination`, `response`, and `true` is **blocked**, then set `response` to a [network error](#) and `break`.

**Note**

*Here we're running the [cross-origin resource policy check](#) against the [parent navigable](#)<sup>p989</sup> rather than `navigable` itself. This is because we care about the same-originness of the embedded content against the parent context, not the navigation source.*

- Set `locationURL` to `response's location URL` given `currentURL's fragment`.
- If `locationURL` is failure or null, then `break`.
- Assert:** `locationURL` is a [URL](#).
- Set `entry's classic history API state`<sup>p1005</sup> to [StructuredSerializeForStorage](#)<sup>p122</sup>(null).
- Let `oldDocState` be `entry's document state`<sup>p1005</sup>.
- Set `entry's document state`<sup>p1005</sup> to a new [document state](#)<sup>p1006</sup>, with
  - [history policy container](#)<sup>p1006</sup>
    - a [clone](#)<sup>p917</sup> of the `oldDocState's history policy container`<sup>p1006</sup> if it is non-null; null otherwise
  - [request referrer](#)<sup>p1006</sup>
    - `oldDocState's request referrer`<sup>p1006</sup>
  - [request referrer policy](#)<sup>p1006</sup>
    - `oldDocState's request referrer policy`<sup>p1006</sup>
  - [initiator origin](#)<sup>p1006</sup>
    - `oldDocState's initiator origin`<sup>p1006</sup>
  - [origin](#)<sup>p1006</sup>
    - `oldDocState's origin`<sup>p1006</sup>
  - [about base URL](#)<sup>p1007</sup>
    - `oldDocState's about base URL`<sup>p1007</sup>
  - [resource](#)<sup>p1007</sup>
    - `oldDocState's resource`<sup>p1007</sup>
  - [ever populated](#)<sup>p1007</sup>
    - `oldDocState's ever populated`<sup>p1007</sup>
  - [navigable target name](#)<sup>p1007</sup>
    - `oldDocState's navigable target name`<sup>p1007</sup>

**Note**

*For the navigation case, only entry referenced `oldDocState`, which was created [early in the navigate algorithm](#)<sup>p1017</sup>. So for navigations, this is functionally just an update to `entry's document state`<sup>p1005</sup>. For the traversal case, it's possible adjacent [session history entries](#)<sup>p1005</sup> also reference `oldDocState`, in which case they will continue doing so even after we've updated `entry's document state`<sup>p1005</sup>.*

**Note**

*`oldDocState's history policy container`<sup>p1006</sup> is only ever non-null here in the traversal case, after we've populated it during a navigation to a URL that [requires storing the policy container in history](#)<sup>p918</sup>.*

### Example

The setup is given by the following [Jake diagram](#)<sup>p993</sup>:

	0	1	2	3
top	/a::/a#foo::/a#bar			/b

Also assume that the [document state](#)<sup>p1005</sup> shared by the entries in steps 0, 1, and 2 has a null [document](#)<sup>p1006</sup>, i.e., [bfcache](#)<sup>p1006</sup> is not in play.

Now consider the scenario where we traverse back to step 2, but this time when fetching /a, the server responds with a `Location` header pointing to /c. That is, *locationURL* points to /c and so we have reached this step instead of [breaking](#) out of the loop.

In this case, we replace the [document state](#)<sup>p1005</sup> of the [session history entry](#)<sup>p1005</sup> occupying step 2, but we do *not* replace the document state of the entries occupying steps 0 and 1. The resulting [Jake diagram](#)<sup>p993</sup> looks like this:

	0	1	2	3
top	/a::/a#foo		/c#bar	/b

Note that we perform this replacement even if we end up in a redirect chain back to the original URL, for example if /c itself had a `Location` header pointing to /a. Such a case would end up like so:

	0	1	2	3
top	/a::/a#foo		/a#bar	/b

20. If *locationURL*'s [scheme](#) is not an [HTTP\(S\) scheme](#), then:
  1. Set entry's [document state](#)<sup>p1005</sup>'s [resource](#)<sup>p1007</sup> to null.
  2. [Break](#).
21. Set *currentURL* to *locationURL*.
22. Set entry's [URL](#)<sup>p1005</sup> to *currentURL*.

### Note

*By the end of this loop we will be in one of these scenarios:*

- *locationURL is failure, because of an unparseable `Location` header.*
- *locationURL is null, either because response is a [network error](#) or because we successfully fetched a non-[network error](#) HTTP(S) response with no `Location` header.*
- *locationURL is a [URL](#) with a non-HTTP(S) scheme.*

20. If *locationURL* is a [URL](#) whose [scheme](#) is not a [fetch scheme](#), then return a new [non-fetch scheme navigation params](#)<sup>p1023</sup>, with
  - [id](#)<sup>p1023</sup>  
*navigationId*
  - [navigable](#)<sup>p1023</sup>  
*navigable*
  - [URL](#)<sup>p1023</sup>  
*locationURL*
  - [target snapshot sandboxing flags](#)<sup>p1023</sup>  
*targetSnapshotParams*'s [sandboxing flags](#)<sup>p1013</sup>
  - [source snapshot has transient activation](#)<sup>p1023</sup>  
*sourceSnapshotParams*'s [has transient activation](#)<sup>p1012</sup>
  - [initiator origin](#)<sup>p1024</sup>  
*responseOrigin*
  - [navigation timing type](#)<sup>p1024</sup>  
*navTimingType*

#### Note

At this point, request's [current URL](#) is the last [URL](#) in the redirect chain with a [fetch scheme](#) before redirecting to a non-[fetch scheme URL](#). It is this [URL](#)'s [origin](#) that will be used as the initiator origin for navigations to non-[fetch scheme URLs](#).

21. If any of the following are true:

- [response](#) is a [network error](#);
- [locationURL](#) is failure; or
- [locationURL](#) is a [URL](#) whose [scheme](#) is a [fetch scheme](#),

then return null.

#### Note

We allow redirects to non-[fetch scheme URLs](#), but redirects to [fetch scheme URLs](#) that aren't [HTTP\(S\)](#) are treated like network errors.

22. [Assert](#): [locationURL](#) is null and [response](#) is not a [network error](#).

23. Let [resultPolicyContainer](#) be the result of [determining navigation params policy container](#)<sup>p918</sup> given [response](#)'s [URL](#), [entry](#)'s [document state](#)<sup>p1005</sup>'s [history policy container](#)<sup>p1006</sup>, [sourceSnapshotParams](#)'s [source policy container](#)<sup>p1012</sup>, null, and [responsePolicyContainer](#).

24. If [navigable](#)'s [container](#)<sup>p991</sup> is an [iframe](#)<sup>p390</sup>, and [response](#)'s [timing allow passed flag](#) is set, then set [container](#)<sup>p991</sup>'s [pending resource-timing start time](#)<sup>p395</sup> to null.

#### Note

If the [iframe](#)<sup>p390</sup> is allowed to report to resource timing, we don't need to run its fallback steps as the normal reporting would happen.

25. Return a new [navigation params](#)<sup>p1013</sup>, with

[id](#)<sup>p1013</sup>

[navigationId](#)

[navigable](#)<sup>p1013</sup>

[navigable](#)

[request](#)<sup>p1013</sup>

[request](#)

[response](#)<sup>p1013</sup>

[response](#)

[fetch controller](#)<sup>p1013</sup>

[fetchController](#)

[commit early hints](#)<sup>p1013</sup>

[commitEarlyHints](#)

[opener policy](#)<sup>p1013</sup>

[responseCOOP](#)

[reserved environment](#)<sup>p1013</sup>

[request](#)'s [reserved client](#)

[origin](#)<sup>p1013</sup>

[responseOrigin](#)

[policy container](#)<sup>p1013</sup>

[resultPolicyContainer](#)

[final sandboxing flag set](#)<sup>p1013</sup>

[finalSandboxFlags](#)

[COOP enforcement result](#)<sup>p1013</sup>

[coopEnforcementResult](#)

[navigation timing type](#)<sup>p1013</sup>

[navTimingType](#)

[about base URL](#)<sup>p1013</sup>

[entry](#)'s [document state](#)<sup>p1005</sup>'s [about base URL](#)<sup>p1007</sup>

An element has a **browsing context scope origin** if its [Document](#)<sup>p130</sup>'s [node navigable](#)<sup>p989</sup> is a [top-level traversable](#)<sup>p990</sup> or if all of its [Document](#)<sup>p130</sup>'s [ancestor navigables](#)<sup>p994</sup> all have [active documents](#)<sup>p989</sup> whose [origins](#) are the [same origin](#)<sup>p899</sup> as the element's [node](#)

document's [origin](#). If an element has a [browsing context scope origin](#)<sup>p1038</sup>, then its value is the [origin](#) of the element's [node document](#).

This definition is broken and needs investigation to see what it was intended to express: see [issue #4703](#).

To **load a document** given [navigation params](#)<sup>p1013</sup> *navigationParams*, [source snapshot params](#)<sup>p1012</sup> *sourceSnapshotParams*, and [origin](#)<sup>p898</sup> *initiatorOrigin*, perform the following steps. They return a [Document](#)<sup>p130</sup> or null.

1. Let *type* be the [computed type](#) of *navigationParams*'s [response](#)<sup>p1013</sup>.
2. If the user agent has been configured to process resources of the given *type* using some mechanism other than rendering the content in a [navigable](#)<sup>p989</sup>, then skip this step. Otherwise, if the *type* is one of the following types:
  - ↪ **an HTML MIME type**  
Return the result of [loading an HTML document](#)<sup>p1059</sup>, given *navigationParams*.
  - ↪ **an XML MIME type that is not an explicitly supported XML MIME type**<sup>p1039</sup>  
Return the result of [loading an XML document](#)<sup>p1060</sup> given *navigationParams* and *type*.
  - ↪ **a JavaScript MIME type**
  - ↪ **a JSON MIME type that is not an explicitly supported JSON MIME type**<sup>p1039</sup>
  - ↪ **"text/css"**<sup>p1474</sup>
  - ↪ **"text/plain"**
  - ↪ **"text/vtt"**<sup>p1474</sup>  
Return the result of [loading a text document](#)<sup>p1060</sup> given *navigationParams* and *type*.
  - ↪ **"multipart/x-mixed-replace"**<sup>p1445</sup>  
Return the result of [loading a multipart/x-mixed-replace document](#)<sup>p1061</sup>, given *navigationParams*, *sourceSnapshotParams*, and *initiatorOrigin*.
  - ↪ **A supported image, video, or audio type**  
Return the result of [loading a media document](#)<sup>p1061</sup> given *navigationParams* and *type*.
  - ↪ **"application/pdf"**
  - ↪ **"text/pdf"**  
If the user agent's [PDF viewer supported](#)<sup>p1178</sup> is true, return the result of [creating a document for inline content that doesn't have a DOM](#)<sup>p1062</sup> given *navigationParams*'s [navigable](#)<sup>p1013</sup>.

Otherwise, proceed onward.

An **explicitly supported XML MIME type** is an [XML MIME type](#) for which the user agent is configured to use an external application to render the content, or for which the user agent has dedicated processing rules. For example, a web browser with a built-in Atom feed viewer would be said to explicitly support the [application/atom+xml](#)<sup>p1473</sup> MIME type.

An **explicitly supported JSON MIME type** is a [JSON MIME type](#) for which the user agent is configured to use an external application to render the content, or for which the user agent has dedicated processing rules.

#### Note

*In both cases, the external application or user agent will either [display the content inline](#)<sup>p1062</sup> directly in *navigationParams*'s [navigable](#)<sup>p1013</sup>, or [hand it off to external software](#)<sup>p1024</sup>. Both happen in the steps below.*

3. If, given *type*, the new resource is to be handled by displaying some sort of inline content, e.g., a native rendering of the content or an error message because the specified type is not supported, then return the result of [creating a document for inline content that doesn't have a DOM](#)<sup>p1062</sup> given *navigationParams*'s [navigable](#)<sup>p1013</sup>, *navigationParams*'s [id](#)<sup>p1013</sup>, and *navigationParams*'s [navigation timing type](#)<sup>p1013</sup>.
4. Otherwise, the document's *type* is such that the resource will not affect *navigationParams*'s [navigable](#)<sup>p1013</sup>, e.g., because the resource is to be handed to an external application or because it is an unknown type that will be processed [as a download](#)<sup>p311</sup>. [Hand-off to external software](#)<sup>p1024</sup> given *navigationParams*'s [response](#)<sup>p1013</sup>, *navigationParams*'s [navigable](#)<sup>p1013</sup>, *navigationParams*'s [final sandboxing flag set](#)<sup>p1013</sup>, *sourceSnapshotParams*'s [has transient activation](#)<sup>p1012</sup>, and *initiatorOrigin*.
5. Return null.

## 7.4.6 Applying the history step <sup>p10</sup><sub>40</sub>

For both navigation and traversal, once we have an idea of where we want to head to in the session history, much of the work comes about in applying that notion to the [traversable navigable](#)<sup>p990</sup> and the relevant [Document](#)<sup>p139</sup>. For navigations, this work generally occurs toward the end of the process; for traversals, it is the beginning.

### 7.4.6.1 Updating the traversable <sup>p10</sup><sub>40</sub>

Ensuring a [traversable](#)<sup>p990</sup> ends up at the right session history step is particularly complex, as it can involve coordinating across multiple [navigable](#)<sup>p989</sup> descendants of the traversable, [populating](#)<sup>p1029</sup> them in parallel, and then synchronizing back up to ensure everyone has the same view of the result. This is further complicated by the existence of synchronous same-document navigations being mixed together with cross-document navigations, and how web pages have come to have certain relative timing expectations.

A **changing navigable continuation state** is used to store information during the [apply the history step](#)<sup>p1041</sup> algorithm, allowing parts of the algorithm to continue only after other parts have finished. It is a [struct](#) with:

**displayed document**

A [Document](#)<sup>p139</sup>

**target entry**

A [session history entry](#)<sup>p1005</sup>

**navigable**

A [navigable](#)<sup>p989</sup>

**update only**

A boolean

Although all updates to the [traversable navigable](#)<sup>p990</sup> end up in the same [apply the history step](#)<sup>p1041</sup> algorithm, each possible entry point comes along with some minor customizations:

To **update for navigable creation/destruction** given a [traversable navigable](#)<sup>p990</sup> *traversable*:

1. Let *step* be *traversable*'s [current session history step](#)<sup>p990</sup>.
2. Return the result of [applying the history step](#)<sup>p1041</sup> *step* to *traversable* given false, null, null, null, and null.

To **apply the push/replace history step** given a non-negative integer *step* and a [history handling behavior](#)<sup>p1014</sup> *historyHandling* to a [traversable navigable](#)<sup>p990</sup> *traversable*:

1. Return the result of [applying the history step](#)<sup>p1041</sup> *step* to *traversable* given false, null, null, null, and *historyHandling*.

#### Note

*Apply the push/replace history step*<sup>p1040</sup> never passes [source snapshot params](#)<sup>p1012</sup> or an initiator [navigable](#)<sup>p989</sup> to [apply the history step](#)<sup>p1041</sup>. This is because those checks are done earlier in the [navigation](#)<sup>p1014</sup> algorithm.

To **apply the reload history step** to a [traversable navigable](#)<sup>p990</sup> *traversable*:

1. Let *step* be *traversable*'s [current session history step](#)<sup>p990</sup>.
2. Return the result of [applying the history step](#)<sup>p1041</sup> *step* to *traversable* given true, null, null, null, and "[reload](#)<sup>p954</sup>".

#### Note

*Apply the reload history step*<sup>p1040</sup> never passes [source snapshot params](#)<sup>p1012</sup> or an initiator [navigable](#)<sup>p989</sup> to [apply the history step](#)<sup>p1041</sup>. This is because reloading is always treated as if it were done by the [navigable](#)<sup>p989</sup> itself, even in cases like `parent.location.reload()`.

To **apply the traverse history step** given a non-negative integer *step* to a [traversable navigable](#)<sup>p990</sup> *traversable*, with [source snapshot params](#)<sup>p1012</sup> *sourceSnapshotParams*, [navigable](#)<sup>p989</sup> *initiatorToCheck*, and [user navigation involvement](#)<sup>p1014</sup> *userInvolvement*:

1. Return the result of [applying the history step](#)<sup>p1041</sup> *step* to *traversable* given true, *sourceSnapshotParams*, *initiatorToCheck*,

*userInvolvement*, and "[traverse](#)<sup>p954</sup>".

Now for the algorithm itself.

To **apply the history step** given a non-negative integer *step* to a [traversable navigable](#)<sup>p990</sup> *traversable*, with boolean *checkForCancelation*, [source snapshot params](#)<sup>p1012</sup>-or-null *sourceSnapshotParams*, [navigable](#)<sup>p989</sup>-or-null *initiatorToCheck*, [user navigation involvement](#)<sup>p1014</sup>-or-null *userInvolvementForNavigateEvents*, and [NavigationType](#)<sup>p953</sup>-or-null *navigationType*, perform the following steps. They return "initiator-disallowed", "canceled-by-beforeunload", "canceled-by-navigate", or "applied".

1. **Assert**: This is running within *traversable*'s [session history traversal queue](#)<sup>p990</sup>.
2. Let *targetStep* be the result of [getting the used step](#)<sup>p1047</sup> given *traversable* and *step*.
3. If *initiatorToCheck* is not null, then:
  1. **Assert**: *sourceSnapshotParams* is not null.
  2. **For each** *navigable* of [get all navigables whose current session history entry will change or reload](#)<sup>p1047</sup>: if *initiatorToCheck* is not [allowed by sandboxing to navigate](#)<sup>p1025</sup> *navigable* given *sourceSnapshotParams*, then return "initiator-disallowed".
4. Let *navigablesCrossingDocuments* be the result of [getting all navigables that might experience a cross-document traversal](#)<sup>p1049</sup> given *traversable* and *targetStep*.
5. If *checkForCancelation* is true, and the result of [checking if unloading is canceled](#)<sup>p1025</sup> given *navigablesCrossingDocuments*, *traversable*, *targetStep*, and *userInvolvementForNavigateEvents* is not "continue", then return that result.
6. Let *changingNavigables* be the result of [get all navigables whose current session history entry will change or reload](#)<sup>p1047</sup> given *traversable* and *targetStep*.
7. Let *nonchangingNavigablesThatStillNeedUpdates* be the result of [getting all navigables that only need history object length/index update](#)<sup>p1048</sup> given *traversable* and *targetStep*.
8. **For each** *navigable* of *changingNavigables*:
  1. Let *targetEntry* be the result of [getting the target history entry](#)<sup>p1048</sup> given *navigable* and *targetStep*.
  2. Set *navigable*'s [current session history entry](#)<sup>p989</sup> to *targetEntry*.
  3. **Set the ongoing navigation**<sup>p1027</sup> for *navigable* to "traversal".
9. Let *totalChangeJobs* be the [size](#) of *changingNavigables*.
10. Let *completedChangeJobs* be 0.
11. Let *changingNavigableContinuations* be an empty [queue](#) of [changing navigable continuation states](#)<sup>p1040</sup>.

#### Note

*This queue is used to split the operations on *changingNavigables* into two parts. Specifically, *changingNavigableContinuations* holds data for the [second part](#)<sup>p1044</sup>.*

12. **For each** *navigable* of *changingNavigables*, [queue a global task](#)<sup>p1125</sup> on the [navigation and traversal task source](#)<sup>p1134</sup> of *navigable*'s [active window](#)<sup>p989</sup> to run the steps:

#### Note

*This set of steps are split into two parts to allow synchronous navigations to be processed before documents unload. State is stored in *changingNavigableContinuations* for the [second part](#)<sup>p1044</sup>.*

1. Let *displayedEntry* be *navigable*'s [active session history entry](#)<sup>p989</sup>.
2. Let *targetEntry* be *navigable*'s [current session history entry](#)<sup>p989</sup>.
3. Let *changingNavigableContinuation* be a [changing navigable continuation state](#)<sup>p1040</sup> with:  
**displayed document**<sup>p1040</sup>  
*displayedEntry*'s [document](#)<sup>p1005</sup>

**target entry**<sup>p1040</sup>  
targetEntry  
**navigable**<sup>p1040</sup>  
navigable  
**update-only**<sup>p1040</sup>  
false

4. If *displayedEntry* is *targetEntry* and *targetEntry*'s *document state*<sup>p1005</sup>'s *reload pending*<sup>p1007</sup> is false, then:
  1. Set *changingNavigableContinuation*'s *update-only*<sup>p1040</sup> to true.
  2. **Enqueue** *changingNavigableContinuation* on *changingNavigableContinuations*.
  3. Abort these steps.

**Note**

*This case occurs due to a **synchronous navigation**<sup>p1023</sup> which already updated the **active session history entry**<sup>p989</sup>.*

5. Switch on *navigationType*:

↪ "**reload**<sup>p954</sup>"

**Assert:** *targetEntry*'s *document state*<sup>p1005</sup>'s *reload pending*<sup>p1007</sup> is true.

↪ "**traverse**<sup>p954</sup>"

**Assert:** *targetEntry*'s *document state*<sup>p1005</sup>'s *ever populated*<sup>p1007</sup> is true.

↪ "**replace**<sup>p953</sup>"

**Assert:** *targetEntry*'s *step*<sup>p1005</sup> is *displayedEntry*'s *step*<sup>p1005</sup> and *targetEntry*'s *document state*<sup>p1005</sup>'s *ever populated*<sup>p1007</sup> is false.

↪ "**push**<sup>p953</sup>"

**Assert:** *targetEntry*'s *step*<sup>p1005</sup> is *displayedEntry*'s *step*<sup>p1005</sup> + 1 and *targetEntry*'s *document state*<sup>p1005</sup>'s *ever populated*<sup>p1007</sup> is false.

6. Let *oldOrigin* be *targetEntry*'s *document state*<sup>p1005</sup>'s *origin*<sup>p1006</sup>.

7. If all of the following are true:

- *navigable* is not *traversable*;
- *targetEntry* is not *navigable*'s *current session history entry*<sup>p989</sup>; and
- *oldOrigin* is the **same**<sup>p899</sup> as *navigable*'s *current session history entry*<sup>p989</sup>'s *document state*<sup>p1005</sup>'s *origin*<sup>p1006</sup>,

then:

1. **Assert:** *userInvolvementForNavigateEvents* is not null.
  2. Let *navigation* be *navigable*'s *active window*<sup>p989</sup>'s *navigation API*<sup>p952</sup>
  3. **Fire a traverse navigate event**<sup>p974</sup> at *navigation* given *targetEntry* and *userInvolvementForNavigateEvents*.
8. If *targetEntry*'s *document*<sup>p1005</sup> is null, or *targetEntry*'s *document state*<sup>p1005</sup>'s *reload pending*<sup>p1007</sup> is true, then:
    1. Let *navTimingType* be "**back\_forward**" if *targetEntry*'s *document*<sup>p1005</sup> is null; otherwise "**reload**".
    2. Let *targetSnapshotParams* be the result of **snapshotting target snapshot params**<sup>p1013</sup> given *navigable*.
    3. Let *potentiallyTargetSpecificSourceSnapshotParams* be *sourceSnapshotParams*.
    4. If *potentiallyTargetSpecificSourceSnapshotParams* is null, then set it to the result of **snapshotting source snapshot params**<sup>p1012</sup> given *navigable*'s *active document*<sup>p989</sup>.

**Note**

*In this case there is no clear source of the traversal/reload. We treat this situation as if navigable navigated itself, but note that some properties of targetEntry's original initiator are preserved in targetEntry's [document state](#)<sup>p1005</sup>, such as the [initiator origin](#)<sup>p1006</sup> and [referrer](#)<sup>p1006</sup>, which will appropriately influence the navigation.*

5. Set targetEntry's [document state](#)<sup>p1005</sup>'s [reload pending](#)<sup>p1007</sup> to false.
6. Let allowPOST be targetEntry's [document state](#)<sup>p1005</sup>'s [reload pending](#)<sup>p1007</sup>.
7. [In parallel](#)<sup>p43</sup>, attempt to populate the history entry's [document](#)<sup>p1029</sup> for targetEntry, given navigable, potentiallyTargetSpecificSourceSnapshotParams, targetSnapshotParams, with [allowPOST](#)<sup>p1029</sup> set to allowPOST and [completionSteps](#)<sup>p1029</sup> set to [queue a global task](#)<sup>p1125</sup> on the [navigation and traversal task source](#)<sup>p1134</sup> given navigable's [active window](#)<sup>p989</sup> to run [afterDocumentPopulated](#).

Otherwise, run [afterDocumentPopulated](#) [immediately](#)<sup>p43</sup>.

In both cases, let [afterDocumentPopulated](#) be the following steps:

1. If targetEntry's [document](#)<sup>p1005</sup> is null, then set [changingNavigableContinuation](#)'s [update-only](#)<sup>p1040</sup> to true.

**Note**

*This means we tried to populate the document, but were unable to do so, e.g. because of the server returning a 204.*

**Note**

*These kinds of failed navigations or traversals will not be signaled to the [navigation API](#)<sup>p949</sup> (e.g., through the promises of any [navigation API method tracker](#)<sup>p964</sup>, or the [navigateerror](#)<sup>p1472</sup> event). Doing so would leak information about the timing of responses from other origins, in the cross-origin case, and providing different results in the cross-origin vs. same-origin cases was deemed too confusing.*

*However, implementations could use this opportunity to clear any promise handlers for the [navigation.transition.finished](#)<sup>p969</sup> promise, as they are guaranteed at this point to never run. And, they might wish to [report a warning to the console](#) if any part of the navigation API initiated these navigations, to make it clear to the web developer why their promises will never settle and events will never fire.*

2. If targetEntry's [document](#)<sup>p1005</sup>'s [origin](#) is not [oldOrigin](#), then set targetEntry's [classic history API state](#)<sup>p1005</sup> to [StructuredSerializeForStorage](#)<sup>p122</sup> (null).

**Note**

*This clears history state when the origin changed vs a previous load of targetEntry without a redirect occurring. This can happen due to a change in CSP sandbox headers.*

3. If all of the following are true:
  - [navigable](#)'s [parent](#)<sup>p989</sup> is null;
  - targetEntry's [document](#)<sup>p1005</sup>'s [browsing context](#)<sup>p999</sup> is not an [auxiliary browsing context](#)<sup>p999</sup> whose [opener browsing context](#)<sup>p998</sup> is non-null; and
  - targetEntry's [document](#)<sup>p1005</sup>'s [origin](#) is not [oldOrigin](#),

then set targetEntry's [document state](#)<sup>p1005</sup>'s [navigable target name](#)<sup>p1007</sup> to the empty string.

4. [Enqueue](#) [changingNavigableContinuation](#) on [changingNavigableContinuations](#).

**Note**

*The rest of this job [runs later](#)<sup>p1044</sup> in this algorithm.*

13. Let [navigablesThatMustWaitBeforeHandlingSyncNavigation](#) be an empty [set](#).

14. While [completedChangeJobs](#) does not equal [totalChangeJobs](#):

1. If *traversable*'s [running nested apply history step](#)<sup>p990</sup> is false, then:
  1. While *traversable*'s [session history traversal queue](#)<sup>p990</sup>'s [algorithm set](#)<sup>p1008</sup> contains one or more [synchronous navigation steps](#)<sup>p1008</sup> with a [target navigable](#)<sup>p1008</sup> not contained in *navigablesThatMustWaitBeforeHandlingSyncNavigation*:
    1. Let *steps* be the first [item](#) in *traversable*'s [session history traversal queue](#)<sup>p990</sup>'s [algorithm set](#)<sup>p1008</sup> that is [synchronous navigation steps](#)<sup>p1008</sup> with a [target navigable](#)<sup>p1008</sup> not contained in *navigablesThatMustWaitBeforeHandlingSyncNavigation*.
    2. [Remove](#) *steps* from *traversable*'s [session history traversal queue](#)<sup>p990</sup>'s [algorithm set](#)<sup>p1008</sup>.
    3. Set *traversable*'s [running nested apply history step](#)<sup>p990</sup> to true.
    4. Run *steps*.
    5. Set *traversable*'s [running nested apply history step](#)<sup>p990</sup> to false.

**Note**

*Synchronous navigations that are intended to take place before this traversal jump the queue at this point, so they can be added to the correct place in *traversable*'s [session history entries](#)<sup>p990</sup> before this traversal potentially unloads their document. [More details can be found here](#)<sup>p1008</sup>.*

2. Let *changingNavigableContinuation* be the result of [dequeuing](#) from *changingNavigableContinuations*.
3. If *changingNavigableContinuation* is nothing, then [continue](#).
4. Let *displayedDocument* be *changingNavigableContinuation*'s [displayed document](#)<sup>p1040</sup>.
5. Let *targetEntry* be *changingNavigableContinuation*'s [target entry](#)<sup>p1040</sup>.
6. Let *navigable* be *changingNavigableContinuation*'s [navigable](#)<sup>p1040</sup>.
7. Let (*scriptHistoryLength*, *scriptHistoryIndex*) be the result of [getting the history object length and index](#)<sup>p1047</sup> given *traversable* and *targetStep*.

**Note**

*These values might have changed since they were last calculated.*

8. [Append](#) *navigable* to *navigablesThatMustWaitBeforeHandlingSyncNavigation*.

**Note**

*Once a navigable has reached this point in traversal, additionally queued synchronous navigation steps are likely to be intended to occur after this traversal rather than before it, so they no longer jump the queue. [More details can be found here](#)<sup>p1008</sup>.*

9. Let *entriesForNavigationAPI* be the result of [getting session history entries for the navigation API](#)<sup>p1011</sup> given *navigable* and *targetStep*.
10. If *changingNavigableContinuation*'s [update-only](#)<sup>p1040</sup> is true, or *targetEntry*'s [document](#)<sup>p1005</sup> is *displayedDocument*, then:

**Note**

*This is a same-document navigation: we proceed without unloading.*

1. [Set the ongoing navigation](#)<sup>p1027</sup> for *navigable* to null.

**Note**

*This allows new [navigations](#)<sup>p1014</sup> of *navigable* to start, whereas during the traversal they were blocked.*

2. [Queue a global task](#)<sup>p1125</sup> on the [navigation and traversal task source](#)<sup>p1134</sup> given *navigable*'s [active window](#)<sup>p989</sup> to perform *afterPotentialUnloads*.
11. Otherwise:

1. [Assert](#): `navigationType` is not null.
  2. [Deactivate](#)<sup>p1045</sup> `displayedDocument`, given `userNavigationInvolvement`, `targetEntry`, `navigationType`, and `afterPotentialUnloads`.
12. In both cases, let `afterPotentialUnloads` be the following steps:
1. Let `previousEntry` be `navigable`'s [active session history entry](#)<sup>p989</sup>.
  2. If `changingNavigableContinuation`'s [update-only](#)<sup>p1040</sup> is false, then [activate history entry](#)<sup>p1047</sup> `targetEntry` for `navigable`.
  3. Let `updateDocument` be an algorithm step which performs [update document for history step application](#)<sup>p1049</sup> given `targetEntry`'s [document](#)<sup>p1005</sup>, `targetEntry`, `changingNavigableContinuation`'s [update-only](#)<sup>p1040</sup>, `scriptHistoryLength`, `scriptHistoryIndex`, `navigationType`, `entriesForNavigationAPI`, and `previousEntry`.
  4. If `targetEntry`'s [document](#)<sup>p1005</sup> is equal to `displayedDocument`, then perform `updateDocument`.
  5. Otherwise, [queue a global task](#)<sup>p1125</sup> on the [navigation and traversal task source](#)<sup>p1134</sup> given `targetEntry`'s [document](#)<sup>p1005</sup>'s [relevant global object](#)<sup>p1083</sup> to perform `updateDocument`.
  6. Increment `completedChangeJobs`.
15. Let `totalNonchangingJobs` be the [size](#) of `nonchangingNavigablesThatStillNeedUpdates`.

#### Note

*This step onwards deliberately waits for all the previous operations to complete, as they include [processing synchronous navigations](#)<sup>p1044</sup> which will also post tasks to update history length and index.*

16. Let `completedNonchangingJobs` be 0.
17. Let `(scriptHistoryLength, scriptHistoryIndex)` be the result of [getting the history object length and index](#)<sup>p1047</sup> given `traversable` and `targetStep`.
18. [For each](#) `navigable` of `nonchangingNavigablesThatStillNeedUpdates`, [queue a global task](#)<sup>p1125</sup> on the [navigation and traversal task source](#)<sup>p1134</sup> given `navigable`'s [active window](#)<sup>p989</sup> to run the steps:
  1. Let `document` be `navigable`'s [active document](#)<sup>p989</sup>.
  2. Set `document`'s [history object](#)<sup>p945</sup>'s [index](#)<sup>p946</sup> to `scriptHistoryIndex`.
  3. Set `document`'s [history object](#)<sup>p945</sup>'s [length](#)<sup>p946</sup> to `scriptHistoryLength`.
  4. Increment `completedNonchangingJobs`.
19. Wait for `completedNonchangingJobs` to equal `totalNonchangingJobs`.
20. Set `traversable`'s [current session history step](#)<sup>p990</sup> to `targetStep`.
21. Return "applied".

To **deactivate a document for a cross-document navigation** given a [Document](#)<sup>p130</sup> `displayedDocument`, a [user navigation involvement](#)<sup>p1014</sup> `userNavigationInvolvement`, a [session history entry](#)<sup>p1005</sup> `targetEntry`, a [NavigationType](#)<sup>p953</sup> `navigationType`, and `afterPotentialUnloads`, which is an algorithm that receives no arguments:

1. Let `navigable` be `displayedDocument`'s [node navigable](#)<sup>p989</sup>.
2. Let `potentiallyTriggerViewTransition` be false.
3. Let `isBrowserUINavigation` be true if `userNavigationInvolvement` is "[browser UI](#)<sup>p1014</sup>"; otherwise false.
4. Set `potentiallyTriggerViewTransition` to the result of calling [can navigation trigger a cross-document view-transition?](#) given `displayedDocument`, `targetEntry`'s [document](#)<sup>p1005</sup>, `navigationType`, and `isBrowserUINavigation`.
5. If `potentiallyTriggerViewTransition` is false, then:
  1. Let `firePageSwapBeforeUnload` be the following step:
    1. [Fire the pageswap event](#)<sup>p1046</sup> given `displayedDocument`, `targetEntry`, `navigationType`, and null.

2. [Set the ongoing navigation](#)<sup>p1027</sup> for *navigable* to null.

**Note**

*This allows new [navigations](#)<sup>p1014</sup> of *navigable* to start, whereas during the traversal they were blocked.*

3. [Unload a document and its descendants](#)<sup>p1065</sup> given *displayedDocument*, *targetEntry*'s [document](#)<sup>p1005</sup>, *afterPotentialUnloads*, and *firePageSwapBeforeUnload*.
6. Otherwise, [queue a global task](#)<sup>p1125</sup> on the [navigation and traversal task source](#)<sup>p1134</sup> given *navigable*'s [active window](#)<sup>p989</sup> to run the steps:

1. Let *proceedWithNavigationAfterViewTransitionCapture* be the following step:

1. [Append the following session history traversal steps](#)<sup>p1008</sup> to *navigable*'s [traversable navigable](#)<sup>p990</sup>:

1. [Set the ongoing navigation](#)<sup>p1027</sup> for *navigable* to null.

**Note**

*This allows new [navigations](#)<sup>p1014</sup> of *navigable* to start, whereas during the traversal they were blocked.*

2. [Unload a document and its descendants](#)<sup>p1065</sup> given *displayedDocument*, *targetEntry*'s [document](#)<sup>p1005</sup>, and *afterPotentialUnloads*.
2. Let *viewTransition* be the result of [setting up a cross-document view-transition](#) given *displayedDocument*, *targetEntry*'s [document](#)<sup>p1005</sup>, *navigationType*, and *proceedWithNavigationAfterViewTransitionCapture*.
3. [Fire the pageswap event](#)<sup>p1046</sup> given *displayedDocument*, *targetEntry*, *navigationType*, and *viewTransition*.
4. If *viewTransition* is null, then run *proceedWithNavigationAfterViewTransitionCapture*.

**Note**

*In the case where a view transition started, the view transitions algorithms are responsible for calling *proceedWithNavigationAfterViewTransitionCapture*.*

To **fire the pageswap event** given a [Document](#)<sup>p130</sup> *displayedDocument*, a [session history entry](#)<sup>p1005</sup> *targetEntry*, a [NavigationType](#)<sup>p953</sup> *navigationType*, and a [ViewTransition](#)-or-null *viewTransition*:

1. [Assert](#): this is running as part of a [task](#)<sup>p1124</sup> queued on *displayedDocument*'s [relevant agent](#)<sup>p1073</sup>'s [event loop](#)<sup>p1123</sup>.
2. Let *navigation* be *displayedDocument*'s [relevant global object](#)<sup>p1083</sup>'s [navigation API](#)<sup>p952</sup>.
3. Let *activation* be null.
4. If all of the following are true:
  - *targetEntry*'s [document](#)<sup>p1005</sup>'s [origin](#) is [same origin](#)<sup>p899</sup> with *displayedDocument*'s [origin](#); and
  - *targetEntry*'s [document](#)<sup>p1005</sup>'s [was created via cross-origin redirects](#)<sup>p134</sup> is false, or *targetEntry*'s [document](#)<sup>p1005</sup>'s [latest entry](#)<sup>p1008</sup> is not null,

then:

1. Let *destinationEntry* be determined by switching on *navigationType*:

↪ "[reload](#)<sup>p954</sup>"

The [current entry](#)<sup>p953</sup> of *navigation*

↪ "[traverse](#)<sup>p954</sup>"

The [NavigationHistoryEntry](#)<sup>p956</sup> in *navigation*'s [entry list](#)<sup>p953</sup> whose [session history entry](#)<sup>p957</sup> is *targetEntry*

↪ "[push](#)<sup>p953</sup>"

↪ "[replace](#)<sup>p953</sup>"

A new [NavigationHistoryEntry](#)<sup>p956</sup> in *displayedDocument*'s [relevant realm](#)<sup>p1083</sup> with its [session history entry](#)<sup>p957</sup> set to *targetEntry*.

2. Set *activation* to a [new NavigationActivation](#)<sup>p969</sup> created in *displayedDocument*'s [relevant realm](#)<sup>p1083</sup>, with [old entry](#)<sup>p969</sup> the [current entry](#)<sup>p953</sup> of *navigation* [new entry](#)<sup>p969</sup> *destinationEntry* [navigation type](#)<sup>p969</sup> *navigationType*

#### Note

*This means that a cross-origin redirect during a navigation would result in a null [activation](#)<sup>p982</sup> in the old document's [PageSwapEvent](#)<sup>p982</sup>, unless the new document is being restored from [bfcache](#)<sup>p1006</sup>.*

5. [Fire an event](#) named [pageswap](#)<sup>p1472</sup> at *displayedDocument*'s [relevant global object](#)<sup>p1083</sup>, using [PageSwapEvent](#)<sup>p982</sup> with its [activation](#)<sup>p982</sup> set to *activation*, and its [viewTransition](#)<sup>p982</sup> set to *viewTransition*.

To **activate history entry** [session history entry](#)<sup>p1005</sup> *entry* for [navigable](#)<sup>p989</sup> *navigable*:

1. [Save persisted state](#)<sup>p1055</sup> to the [navigable](#)<sup>p989</sup>'s [active session history entry](#)<sup>p989</sup>.
2. Let *newDocument* be *entry*'s [document](#)<sup>p1005</sup>.
3. [Assert](#): *newDocument*'s [is initial about:blank](#)<sup>p131</sup> is false, i.e., we never traverse back to the [initial about:blank](#)<sup>p131</sup> [Document](#)<sup>p130</sup> because it always gets [replaced](#)<sup>p1015</sup> when we navigate away from it.
4. Set *navigable*'s [active session history entry](#)<sup>p989</sup> to *entry*.
5. [Make active](#)<sup>p1051</sup> *newDocument*.

To **get the used step** given a [traversable navigable](#)<sup>p990</sup> *traversable*, and a non-negative integer *step*, perform the following steps. They return a non-negative integer.

1. Let *steps* be the result of [getting all used history steps](#)<sup>p1011</sup> within *traversable*.
2. Return the greatest [item](#) in *steps* that is less than or equal to *step*.

#### Note

*This caters for situations where there's no [session history entry](#)<sup>p1005</sup> with [step](#)<sup>p1005</sup> *step*, due to the removal of a [navigable](#)<sup>p989</sup>.*

To **get the history object length and index** given a [traversable navigable](#)<sup>p990</sup> *traversable*, and a non-negative integer *step*, perform the following steps. They return a [tuple](#) of two non-negative integers.

1. Let *steps* be the result of [getting all used history steps](#)<sup>p1011</sup> within *traversable*.
2. Let *scriptHistoryLength* be the [size](#) of *steps*.
3. [Assert](#): *steps* [contains](#) *step*.

#### Note

*It is assumed that *step* has been adjusted by [getting the used step](#)<sup>p1047</sup>.*

4. Let *scriptHistoryIndex* be the index of *step* in *steps*.
5. Return (*scriptHistoryLength*, *scriptHistoryIndex*).

To **get all navigables whose current session history entry will change or reload** given a [traversable navigable](#)<sup>p990</sup> *traversable*, and a non-negative integer *targetStep*, perform the following steps. They return a [list](#) of [navigables](#)<sup>p989</sup>.

1. Let *results* be an empty [list](#).
2. Let *navigablesToCheck* be « *traversable* ».

#### Note

*This list is extended in the loop below.*

3. [For each](#) [navigable](#) of [navigablesToCheck](#):

1. Let [targetEntry](#) be the result of [getting the target history entry](#)<sup>p1048</sup> given [navigable](#) and [targetStep](#).
2. If [targetEntry](#) is not [navigable](#)'s [current session history entry](#)<sup>p989</sup> or [targetEntry](#)'s [document state](#)<sup>p1005</sup>'s [reload pending](#)<sup>p1007</sup> is true, then [append](#) [navigable](#) to [results](#).
3. If [targetEntry](#)'s [document](#)<sup>p1005</sup> is [navigable](#)'s [document](#)<sup>p989</sup>, and [targetEntry](#)'s [document state](#)<sup>p1005</sup>'s [reload pending](#)<sup>p1007</sup> is false, then [extend](#) [navigablesToCheck](#) with the [child navigables](#)<sup>p992</sup> of [navigable](#).

**Note**

Adding [child navigables](#)<sup>p992</sup> to [navigablesToCheck](#) means those [navigables](#) will also be checked by this loop. [Child navigables](#)<sup>p992</sup> are only checked if the [navigable](#)'s [active document](#)<sup>p989</sup> will not change as part of this traversal.

4. Return [results](#).

To **get all navigables that only need history object length/index update** given a [traversable navigable](#)<sup>p990</sup> [traversable](#), and a non-negative integer [targetStep](#), perform the following steps. They return a [list](#) of [navigables](#)<sup>p989</sup>.

**Note**

Other [navigables](#)<sup>p989</sup> might not be impacted by the traversal. For example, if the response is a 204, the currently active document will remain. Additionally, going 'back' after a 204 will change the [current session history entry](#)<sup>p989</sup>, but the [active session history entry](#)<sup>p989</sup> will already be correct.

1. Let [results](#) be an empty [list](#).
2. Let [navigablesToCheck](#) be « [traversable](#) ».

**Note**

This list is extended in the loop below.

3. [For each](#) [navigable](#) of [navigablesToCheck](#):

1. Let [targetEntry](#) be the result of [getting the target history entry](#)<sup>p1048</sup> given [navigable](#) and [targetStep](#).
2. If [targetEntry](#) is [navigable](#)'s [current session history entry](#)<sup>p989</sup> and [targetEntry](#)'s [document state](#)<sup>p1005</sup>'s [reload pending](#)<sup>p1007</sup> is false, then:
  1. [Append](#) [navigable](#) to [results](#).
  2. [Extend](#) [navigablesToCheck](#) with [navigable](#)'s [child navigables](#)<sup>p992</sup>.

**Note**

Adding [child navigables](#)<sup>p992</sup> to [navigablesToCheck](#) means those [navigables](#) will also be checked by this loop. [Child navigables](#)<sup>p992</sup> are only checked if the [navigable](#)'s [active document](#)<sup>p989</sup> will not change as part of this traversal.

4. Return [results](#).

To **get the target history entry** given a [navigable](#)<sup>p989</sup> [navigable](#), and a non-negative integer [step](#), perform the following steps. They return a [session history entry](#)<sup>p1005</sup>.

1. Let [entries](#) be the result of [getting session history entries](#)<sup>p1010</sup> for [navigable](#).
2. Return the [item](#) in [entries](#) that has the greatest [step](#)<sup>p1005</sup> less than or equal to [step](#).

**Example**

To see why [getting the target history entry](#)<sup>p1048</sup> returns the entry with the greatest [step](#)<sup>p1005</sup> less than or equal to the input step, consider the following [jake diagram](#)<sup>p993</sup>:

	0	1	2	3
top /t				/t#foo

	0	1	2	3
frames[0]	/i-0-a	/i-0-b		

For the input step 1, the target history entry for the `top` navigable is the `/t` entry, whose [step<sup>p1005</sup>](#) is 0, while the target history entry for the `frames[0]` navigable is the `/i-0-b` entry, whose [step<sup>p1005</sup>](#) is 1:

	0	1	2	3
top	/t		/t#foo	
frames[0]	/i-0-a	/i-0-b		

Similarly, given the input step 3 we get the `top` entry whose [step<sup>p1005</sup>](#) is 3, and the `frames[0]` entry whose [step<sup>p1005</sup>](#) is 1:

	0	1	2	3
top	/t		/t#foo	
frames[0]	/i-0-a	/i-0-b		

To **get all navigables that might experience a cross-document traversal** given a [traversable navigable<sup>p990</sup>](#) `traversable`, and a non-negative integer `targetStep`, perform the following steps. They return a [list](#) of [navigables<sup>p989</sup>](#).

#### Note

From `traversable`'s [session history traversal queue<sup>p990</sup>](#)'s perspective, these documents are candidates for going cross-document during the traversal described by `targetStep`. They will not experience a cross-document traversal if the status code for their target document is HTTP 204 No Content.

Note that if a given [navigable<sup>p989</sup>](#) might experience a cross-document traversal, this algorithm will return [navigable<sup>p989</sup>](#) but not its [child navigables<sup>p992</sup>](#). Those would end up [unloaded<sup>p1064</sup>](#), not traversed.

1. Let `results` be an empty [list](#).
2. Let `navigablesToCheck` be « `traversable` ».

#### Note

This list is extended in the loop below.

3. **For each** `navigable` of `navigablesToCheck`:
  1. Let `targetEntry` be the result of [getting the target history entry<sup>p1048</sup>](#) given `navigable` and `targetStep`.
  2. If `targetEntry`'s [document<sup>p1005</sup>](#) is not `navigable`'s [document<sup>p989</sup>](#) or `targetEntry`'s [document state<sup>p1005</sup>](#)'s [reload pending<sup>p1007</sup>](#) is true, then [append](#) `navigable` to `results`.

#### Note

Although `navigable`'s [active history entry<sup>p989</sup>](#) can change synchronously, the new entry will always have the same [Document<sup>p138</sup>](#), so accessing `navigable`'s [document<sup>p989</sup>](#) is reliable.

3. Otherwise, [extend](#) `navigablesToCheck` with `navigable`'s [child navigables<sup>p992</sup>](#).

#### Note

Adding [child navigables<sup>p992</sup>](#) to `navigablesToCheck` means those navigables will also be checked by this loop. [Child navigables<sup>p992</sup>](#) are only checked if the `navigable`'s [active document<sup>p989</sup>](#) will not change as part of this traversal.

4. Return `results`.

### 7.4.6.2 Updating the document §<sup>p10</sup> 49

To **update document for history step application** given a [Document<sup>p138</sup>](#) `document`, a [session history entry<sup>p1005</sup>](#) `entry`, a boolean

*doNotReactivate*, integers *scriptHistoryLength* and *scriptHistoryIndex*, [NavigationType](#)<sup>p953</sup>-or-null *navigationType*, an optional [list](#) of [session history entries](#)<sup>p1005</sup> *entriesForNavigationAPI*, and an optional [session history entry](#)<sup>p1005</sup> *previousEntryForActivation*:

1. Let *documentIsNew* be true if *document*'s [latest entry](#)<sup>p1008</sup> is null; otherwise false.
2. Let *documentsEntryChanged* be true if *document*'s [latest entry](#)<sup>p1008</sup> is not *entry*; otherwise false.
3. Set *document*'s [history object](#)<sup>p945</sup>'s [index](#)<sup>p946</sup> to *scriptHistoryIndex*.
4. Set *document*'s [history object](#)<sup>p945</sup>'s [length](#)<sup>p946</sup> to *scriptHistoryLength*.
5. Let *navigation* be *history*'s [relevant global object](#)<sup>p1083</sup>'s [navigation API](#)<sup>p952</sup>.
6. If *documentsEntryChanged* is true, then:
  1. Let *oldURL* be *document*'s [latest entry](#)<sup>p1008</sup>'s [URL](#)<sup>p1005</sup>.
  2. Set *document*'s [latest entry](#)<sup>p1008</sup> to *entry*.
  3. [Restore the history object state](#)<sup>p1051</sup> given *document* and *entry*.
  4. If *documentIsNew* is false, then:
    1. [Assert](#): *navigationType* is not null.
    2. [Update the navigation API entries for a same-document navigation](#)<sup>p955</sup> given *navigation*, *entry*, and *navigationType*.
    3. [Fire an event](#) named [popstate](#)<sup>p1472</sup> at *document*'s [relevant global object](#)<sup>p1083</sup>, using [PopStateEvent](#)<sup>p981</sup>, with the [state](#)<sup>p981</sup> attribute initialized to *document*'s [history object](#)<sup>p945</sup>'s [state](#)<sup>p946</sup> and [hasUAVisualTransition](#)<sup>p981</sup> initialized to true if a visual transition, to display a cached rendered state of the [latest entry](#)<sup>p1008</sup>, was done by the user agent.
    4. [Restore persisted state](#)<sup>p1055</sup> given *entry*.
    5. If *oldURL*'s [fragment](#) is not equal to *entry*'s [URL](#)<sup>p1005</sup>'s [fragment](#), then [queue a global task](#)<sup>p1125</sup> on the [DOM manipulation task source](#)<sup>p1134</sup> given *document*'s [relevant global object](#)<sup>p1083</sup> to [fire an event](#) named [hashchange](#)<sup>p1471</sup> at *document*'s [relevant global object](#)<sup>p1083</sup>, using [HashChangeEvent](#)<sup>p981</sup>, with the [oldURL](#)<sup>p981</sup> attribute initialized to the [serialization](#) of *oldURL* and the [newURL](#)<sup>p981</sup> attribute initialized to the [serialization](#) of *entry*'s [URL](#)<sup>p1005</sup>.
5. Otherwise:
  1. [Assert](#): *entriesForNavigationAPI* is given.
  2. [Restore persisted state](#)<sup>p1055</sup> given *entry*.
  3. [Initialize the navigation API entries for a new document](#)<sup>p954</sup> given *navigation*, *entriesForNavigationAPI*, and *entry*.
7. If all the following are true:
  - *previousEntryForActivation* is given;
  - *navigationType* is non-null; and
  - *navigationType* is "[reload](#)<sup>p954</sup>" or *previousEntryForActivation*'s [document](#)<sup>p1005</sup> is not *document*,then:
  1. If *navigation*'s [activation](#)<sup>p969</sup> is null, then set *navigation*'s [activation](#)<sup>p969</sup> to a new [NavigationActivation](#)<sup>p969</sup> object in *navigation*'s [relevant realm](#)<sup>p1083</sup>.
  2. Let *previousEntryIndex* be the result of [getting the navigation API entry index](#)<sup>p953</sup> of *previousEntryForActivation* within *navigation*.
  3. If *previousEntryIndex* is non-negative, then set *activation*'s [old entry](#)<sup>p969</sup> to *navigation*'s [entry list](#)<sup>p953</sup>[*previousEntryIndex*].
  4. Otherwise, if all the following are true:

- `navigationType` is "`replace`<sup>p953</sup>";
- `previousEntryForActivation`'s `document state`<sup>p1005</sup>'s `origin`<sup>p1006</sup> is `same origin`<sup>p899</sup> with `document`'s `origin`; and
- `previousEntryForActivation`'s `document`<sup>p1005</sup>'s `initial about:blank`<sup>p131</sup> is false,

then set `activation`'s `old entry`<sup>p969</sup> to a new `NavigationHistoryEntry`<sup>p956</sup> in `navigation`'s `relevant realm`<sup>p1083</sup>, whose `session history entry`<sup>p957</sup> is `previousEntryForActivation`.

5. Set `activation`'s `new entry`<sup>p969</sup> to `navigation`'s `current entry`<sup>p953</sup>.
6. Set `activation`'s `navigation type`<sup>p969</sup> to `navigationType`.
8. If `documentIsNew` is true, then:
  1. `Try to scroll to the fragment`<sup>p1052</sup> for `document`.
  2. At this point **scripts may run for the newly-created document** `document`.
9. Otherwise, if `documentsEntryChanged` is false and `doNotReactivate` is false, then:
  1. **Assert:** `entriesForNavigationAPI` is given.
  2. **Reactivate**<sup>p1051</sup> `document` given `entry` and `entriesForNavigationAPI`.

#### Note

`documentsEntryChanged` can be false for one of two reasons: either we are restoring from `bfcache`<sup>p1006</sup>, or we are asynchronously finishing up a synchronous navigation which already synchronously set `document`'s `latest entry`<sup>p1008</sup>. The `doNotReactivate` argument distinguishes between these two cases.

To **restore the history object state** given `Document`<sup>p130</sup> `document` and `session history entry`<sup>p1005</sup> `entry`:

1. Let `targetRealm` be `document`'s `relevant realm`<sup>p1083</sup>.
2. Let `state` be `StructuredDeserialize`<sup>p122</sup>(`entry`'s `classic history API state`<sup>p1005</sup>, `targetRealm`). If this throws an exception, catch it and let `state` be null.
3. Set `document`'s `history object`<sup>p945</sup>'s `state`<sup>p946</sup> to `state`.

To **make active** a `Document`<sup>p130</sup> `document`:

1. Let `window` be `document`'s `relevant global object`<sup>p1083</sup>.
2. Set `document`'s `browsing context`<sup>p999</sup>'s `WindowProxy`<sup>p934</sup>'s `[[Window]]`<sup>p934</sup> internal slot value to `window`.
3. Set `document`'s `visibility state`<sup>p826</sup> to `document`'s `node navigable`<sup>p989</sup>'s `traversable navigable`<sup>p990</sup>'s `system visibility state`<sup>p990</sup>.
4. **Queue** a new `VisibilityStateEntry`<sup>p827</sup> whose `visibility state`<sup>p827</sup> is `document`'s `visibility state`<sup>p826</sup> and whose `timestamp`<sup>p827</sup> is zero.
5. Set `window`'s `relevant settings object`<sup>p1083</sup>'s `execution ready flag`<sup>p1076</sup>.

To **reactivate** a `Document`<sup>p130</sup> `document` given a `session history entry`<sup>p1005</sup> `reactivatedEntry` and a list of `session history entries`<sup>p1005</sup> `entriesForNavigationAPI`:

#### Note

This algorithm updates `document` after it has come out of `bfcache`<sup>p1006</sup>, i.e., after it has been made `fully active`<sup>p1003</sup> again. Other specifications that want to watch for this change to the `fully active`<sup>p1003</sup> state are encouraged to add steps into this algorithm, so that the ordering of events that happen in effect of the change is clear.

1. **For each** `formControl` of form controls in `document` with an `autofill field name`<sup>p610</sup> of "`off`<sup>p606</sup>", invoke the `reset algorithm`<sup>p637</sup> for `formControl`.
2. If `document`'s `suspended timer handles`<sup>p1064</sup> is not empty:
  1. **Assert:** `document`'s `suspension time`<sup>p1064</sup> is not zero.

2. Let *suspendDuration* be the [current high resolution time](#) minus *document*'s [suspension time](#)<sup>p1064</sup>.
3. Let *activeTimers* be *document*'s [relevant global object](#)<sup>p1083</sup>'s [map of active timers](#)<sup>p1164</sup>.
4. For each *handle* in *document*'s [suspended timer handles](#)<sup>p1064</sup>, if *activeTimers*[*handle*] [exists](#), then increase *activeTimers*[*handle*] by *suspendDuration*.
3. [Update the navigation API entries for reactivation](#)<sup>p954</sup> given *document*'s [relevant global object](#)<sup>p1083</sup>'s [navigation API](#)<sup>p952</sup>, *entriesForNavigationAPI*, and *reactivatedEntry*.
4. If *document*'s [current document readiness](#)<sup>p133</sup> is "complete", and *document*'s [page showing](#)<sup>p1064</sup> flag is false, then:
  1. Set *document*'s [page showing](#)<sup>p1064</sup> flag to true.
  2. Set *document*'s [has been revealed](#)<sup>p1053</sup> to false.
  3. [Update the visibility state](#)<sup>p826</sup> of *document* to "visible".
  4. [Fire a page transition event](#)<sup>p983</sup> named [pageshow](#)<sup>p1472</sup> at *document*'s [relevant global object](#)<sup>p1083</sup> with true.

To **try to scroll to the fragment** for a [Document](#)<sup>p130</sup> *document*, perform the following steps [in parallel](#)<sup>p43</sup>:

1. Wait for an [implementation-defined](#) amount of time. (This is intended to allow the user agent to optimize the user experience in the face of performance concerns.)
2. [Queue a global task](#)<sup>p1125</sup> on the [navigation and traversal task source](#)<sup>p1134</sup> given *document*'s [relevant global object](#)<sup>p1083</sup> to run these steps:
  1. If *document* has no parser, or its parser has [stopped parsing](#)<sup>p1358</sup>, or the user agent has reason to believe the user is no longer interested in scrolling to the [fragment](#), then abort these steps.
  2. [Scroll to the fragment](#)<sup>p1054</sup> given *document*.
  3. If *document*'s [indicated part](#)<sup>p1054</sup> is still null, then [try to scroll to the fragment](#)<sup>p1052</sup> for *document*.

To **make document unsalvageable**, given a [Document](#)<sup>p130</sup> *document* and a string *reason*:

1. Let *details* be a new [not restored reason details](#)<sup>p985</sup> whose [reason](#)<sup>p985</sup> is *reason*.
2. [Append](#) *details* to *document*'s [bfcache blocking details](#)<sup>p131</sup>.
3. Set *document*'s [salvageable](#)<sup>p1064</sup> state to false.

To **build not restored reasons for document state** given [Document](#)<sup>p130</sup> *document*:

1. Let *notRestoredReasonsForDocument* be a new [not restored reasons](#)<sup>p988</sup>.
2. Set *notRestoredReasonsForDocument*'s [URL](#)<sup>p988</sup> to *document*'s [URL](#).
3. If *document*'s [node navigable](#)<sup>p989</sup>'s [container](#)<sup>p991</sup> is an [iframe](#)<sup>p390</sup> element, then:
  1. Set *notRestoredReasonsForDocument*'s [src](#)<sup>p988</sup> to the value of *document*'s [node navigable](#)<sup>p989</sup>'s [container](#)<sup>p991</sup>'s [src](#)<sup>p391</sup> attribute.
  2. Set *notRestoredReasonsForDocument*'s [id](#)<sup>p988</sup> to the value of *document*'s [node navigable](#)<sup>p989</sup>'s [container](#)<sup>p991</sup>'s [id](#)<sup>p154</sup> attribute.
  3. Set *notRestoredReasonsForDocument*'s [name](#)<sup>p988</sup> to the value of *document*'s [node navigable](#)<sup>p989</sup>'s [container](#)<sup>p991</sup>'s [name](#)<sup>p395</sup> attribute.
4. Set *notRestoredReasonsForDocument*'s [reasons](#)<sup>p988</sup> to a [clone](#) of *document*'s [bfcache blocking details](#)<sup>p131</sup>.
5. [For each](#) *navigable* of *document*'s [document-tree child navigables](#)<sup>p995</sup>:
  1. Let *childDocument* be *navigable*'s [active document](#)<sup>p989</sup>.
  2. [Build not restored reasons for document state](#)<sup>p1052</sup> given *childDocument*.
  3. [Append](#) *childDocument*'s [not restored reasons](#)<sup>p988</sup> to *notRestoredReasonsForDocument*'s [children](#)<sup>p988</sup>.
6. Set *document*'s [node navigable](#)<sup>p989</sup>'s [active session history entry](#)<sup>p989</sup>'s [document state](#)<sup>p1005</sup>'s [not restored reasons](#)<sup>p1007</sup> to

*notRestoredReasonsForDocument*.

To **build not restored reasons for a top-level traversable and its descendants** given [top-level traversable](#)<sup>p990</sup> *topLevelTraversable*:

1. [Build not restored reasons for document state](#)<sup>p1052</sup> given *topLevelTraversable*'s [active document](#)<sup>p989</sup>.
2. Let *crossOriginDescendants* be an empty [list](#).
3. [For each](#) *childNavigable* of *topLevelTraversable*'s [active document](#)<sup>p989</sup>'s [descendant navigables](#)<sup>p994</sup>:
  1. If *childNavigable*'s [active document](#)<sup>p989</sup>'s [origin](#) is not [same origin](#)<sup>p899</sup> with *topLevelTraversable*'s [active document](#)<sup>p989</sup>'s [origin](#), then [append](#) *childNavigable* to *crossOriginDescendants*.
4. Let *crossOriginDescendantsPreventsBfcache* be false.
5. [For each](#) *crossOriginNavigable* of *crossOriginDescendants*:
  1. Let *reasonsForCrossOriginChild* be *crossOriginNavigable*'s [active document](#)<sup>p989</sup>'s [document state](#)<sup>p1006</sup>'s [not restored reasons](#)<sup>p1007</sup>.
  2. If *reasonsForCrossOriginChild*'s [reasons](#)<sup>p988</sup> is not empty, set *crossOriginDescendantsPreventsBfcache* to true.
  3. Set *reasonsForCrossOriginChild*'s [URL](#)<sup>p988</sup> to null.
  4. Set *reasonsForCrossOriginChild*'s [reasons](#)<sup>p988</sup> to null.
  5. Set *reasonsForCrossOriginChild*'s [children](#)<sup>p988</sup> to null.
6. If *crossOriginDescendantsPreventsBfcache* is true, [make document unsalvageable](#)<sup>p1052</sup> given *topLevelTraversable*'s [active document](#)<sup>p989</sup> and ["masked"](#)<sup>p985</sup>.

#### 7.4.6.3 Revealing the document <sup>§ p10</sup><sub>53</sub>

A [Document](#)<sup>p130</sup> has a boolean **has been revealed**, initially false. It is used to ensure that the [pagereveal](#)<sup>p1472</sup> event is fired once for each activation of the [Document](#)<sup>p130</sup> (once when it's rendered initially, and once for each [reactivation](#)<sup>p1051</sup>).

To **reveal** a [Document](#)<sup>p130</sup> *document*:

1. If *document*'s [has been revealed](#)<sup>p1053</sup> is true, then return.
2. Set *document*'s [has been revealed](#)<sup>p1053</sup> to true.
3. Let *transition* be the result of [resolving inbound cross-document view-transition](#) for *document*.
4. [Fire an event](#) named [pagereveal](#)<sup>p1472</sup> at *document*'s [relevant global object](#)<sup>p1083</sup>, using [PageRevealEvent](#)<sup>p982</sup> with its [viewTransition](#)<sup>p982</sup> set to *transition*.
5. If *transition* is not null, then:
  1. [Prepare to run script](#)<sup>p1097</sup> given *document*'s [relevant settings object](#)<sup>p1083</sup>.
  2. [Activate](#) *transition*.
  3. [Clean up after running script](#)<sup>p1097</sup> given *document*'s [relevant settings object](#)<sup>p1083</sup>.

#### Note

Activating a view transition might resolve/reject promises, so by wrapping the activation with prepare/cleanup we ensure those promises are handled before the next rendering step.

#### Note

Though [pagereveal](#)<sup>p1472</sup> is guaranteed to be fired during the first [update the rendering](#)<sup>p1128</sup> step that displays an up-to-date version of the page, user agents are free to display a cached frame of the page before firing it. This prevents the presence of a [pagereveal](#)<sup>p1472</sup> handler from delaying the presentation of such cached frame.

#### 7.4.6.4 Scrolling to a fragment <sup>p10</sup><sub>54</sub>

To **scroll to the fragment** given a [Document](#)<sup>p130</sup> *document*:

1. If *document*'s [indicated part](#)<sup>p1054</sup> is null, then set *document*'s [target element](#)<sup>p1054</sup> to null.
2. Otherwise, if *document*'s [indicated part](#)<sup>p1054</sup> is [top of the document](#)<sup>p1054</sup>, then:
  1. Set *document*'s [target element](#)<sup>p1054</sup> to null.
  2. [Scroll to the beginning of the document](#) for *document*. [\[CSSOMVIEW\]](#)<sup>p1477</sup>
  3. Return.
3. Otherwise:
  1. [Assert](#): *document*'s [indicated part](#)<sup>p1054</sup> is an element.
  2. Let *target* be *document*'s [indicated part](#)<sup>p1054</sup>.
  3. Set *document*'s [target element](#)<sup>p1054</sup> to *target*.
  4. Run the [ancestor details revealing algorithm](#)<sup>p640</sup> on *target*.
  5. Run the [ancestor hidden-until-found revealing algorithm](#)<sup>p825</sup> on *target*.
  6. [Scroll target into view](#), with *behavior* set to "auto", *block* set to "start", and *inline* set to "nearest". [\[CSSOMVIEW\]](#)<sup>p1477</sup>
  7. Run the [focusing steps](#)<sup>p842</sup> for *target*, with the [Document](#)<sup>p130</sup>'s [viewport](#) as the *fallback target*.
  8. Move the [sequential focus navigation starting point](#)<sup>p844</sup> to *target*.

A [Document](#)<sup>p130</sup>'s **indicated part** is the one that its [URL](#)'s [fragment](#) identifies, or null if the fragment does not identify anything. The semantics of the [fragment](#) in terms of mapping it to a node is defined by the specification that defines the [MIME type](#) used by the [Document](#)<sup>p130</sup> (for example, the processing of [fragments](#) for [XML MIME types](#) is the responsibility of RFC7303). [\[RFC7303\]](#)<sup>p1482</sup>

There is also a **target element** for each [Document](#)<sup>p130</sup>, which is used in defining the [:target](#)<sup>p784</sup> pseudo-class and is updated by the above algorithm. It is initially null.

For an [HTML document](#) *document*, its [indicated part](#)<sup>p1054</sup> is the result of [selecting the indicated part](#)<sup>p1054</sup> given *document* and *document*'s [URL](#).

To **select the indicated part** given a [Document](#)<sup>p130</sup> *document* and a [URL](#) *url*:

1. If *document*'s [URL](#) does not [equal](#) *url* with [exclude fragments](#) set to true, then return null.
2. Let *fragment* be *url*'s [fragment](#).
3. If *fragment* is the empty string, then return the special value **top of the document**.
4. Let *potentialIndicatedElement* be the result of [finding a potential indicated element](#)<sup>p1054</sup> given *document* and *fragment*.
5. If *potentialIndicatedElement* is not null, then return *potentialIndicatedElement*.
6. Let *fragmentBytes* be the result of [percent-decoding](#) *fragment*.
7. Let *decodedFragment* be the result of running [UTF-8 decode without BOM](#) on *fragmentBytes*.
8. Set *potentialIndicatedElement* to the result of [finding a potential indicated element](#)<sup>p1054</sup> given *document* and *decodedFragment*.
9. If *potentialIndicatedElement* is not null, then return *potentialIndicatedElement*.
10. If *decodedFragment* is an [ASCII case-insensitive](#) match for the string **top**, then return the [top of the document](#)<sup>p1054</sup>.
11. Return null.

To **find a potential indicated element** given a [Document](#)<sup>p130</sup> *document* and a string *fragment*, run these steps:

1. If there is an element [in the document tree](#) whose [root](#) is *document* and that has an [ID](#) equal to *fragment*, then return the

first such element in [tree order](#).

2. If there is an [a<sup>p257</sup>](#) element in the [document tree](#) whose [root](#) is *document* that has a [name<sup>p1427</sup>](#) attribute whose value is equal to *fragment*, then return the first such element in [tree order](#).
3. Return null.

#### 7.4.6.5 Persisted history entry state §<sup>p10</sup> 55

To **save persisted state** to a [session history entry<sup>p1005</sup>](#) entry:

1. Set the [scroll position data<sup>p1005</sup>](#) of entry to contain the scroll positions for all of entry's [document<sup>p1005</sup>](#)'s [restorable scrollable regions<sup>p1055</sup>](#).
2. Optionally, update entry's [persisted user state<sup>p1005</sup>](#) to reflect any state that the user agent wishes to persist, such as the values of form fields.

To **restore persisted state** from a [session history entry<sup>p1005</sup>](#) entry:

1. If entry's [scroll restoration mode<sup>p1005</sup>](#) is "[auto<sup>p1886</sup>](#)", and entry's [document<sup>p1005</sup>](#)'s [relevant global object<sup>p1083</sup>](#)'s [navigation API<sup>p952</sup>](#)'s [suppress normal scroll restoration during ongoing navigation<sup>p964</sup>](#) is false, then [restore scroll position data<sup>p1055</sup>](#) given entry.

##### Note

*The user agent not restoring scroll positions does not imply that scroll positions will be left at any particular value (e.g., (0,0)). The actual scroll position depends on the navigation type and the user agent's particular caching strategy. So web applications cannot assume any particular scroll position but rather are urged to set it to what they want it to be.*

##### Note

*If [suppress normal scroll restoration during ongoing navigation<sup>p964</sup>](#) is true, then [restoring scroll position data<sup>p1055</sup>](#) might still happen at a later point, as part of [finishing<sup>p979</sup>](#) the relevant [NavigateEvent<sup>p978</sup>](#), or via a [navigateEvent.scroll\(\)<sup>p972</sup>](#) method call.*

2. Optionally, update other aspects of entry's [document<sup>p1005</sup>](#) and its rendering, for instance values of form fields, that the user agent had previously recorded in entry's [persisted user state<sup>p1005</sup>](#).

##### Note

*This can even include updating the [dir<sup>p168</sup>](#) attribute of [textarea<sup>p579</sup>](#) elements or [input<sup>p528</sup>](#) elements whose [type<sup>p523</sup>](#) attribute is in the [Text<sup>p527</sup>](#), [Search<sup>p527</sup>](#), [Telephone<sup>p528</sup>](#), [URL<sup>p529</sup>](#), or [Email<sup>p530</sup>](#) state, if the persisted state includes the directionality of user input in such controls.*

##### Note

*Restoring the value of form controls as part of this process does not fire any [input](#) or [change<sup>p1471</sup>](#) events, but can trigger the `formStateRestoreCallback` of [form-associated custom elements<sup>p760</sup>](#).*

Each [Document<sup>p138</sup>](#) has a boolean **has been scrolled by the user**, initially false. If the user scrolls the document, the user agent must set that document's [has been scrolled by the user<sup>p1055</sup>](#) to true.

The **restorable scrollable regions** of a [Document<sup>p138</sup>](#) document are document's [viewport](#), and all of document's scrollable regions excepting any [navigable containers<sup>p991</sup>](#).

##### Note

*[Child navigable<sup>p992</sup>](#) scroll restoration is handled as part of state restoration for the [session history entry<sup>p1005</sup>](#) for those [navigables<sup>p989</sup>](#), [Document<sup>p138</sup>](#)s.*

To **restore scroll position data** given a [session history entry<sup>p1005</sup>](#) entry:

1. Let *document* be entry's [document<sup>p1005</sup>](#).

2. If document's [has been scrolled by the user](#)<sup>p1055</sup> is true, then the user agent should return.
3. The user agent should attempt to use entry's [scroll position data](#)<sup>p1005</sup> to restore the scroll positions of entry's [document](#)<sup>p1005</sup>'s [restorable scrollable regions](#)<sup>p1055</sup>. The user agent may continue to attempt to do so periodically, until document's [has been scrolled by the user](#)<sup>p1055</sup> becomes true.

#### Note

*This is formulated as an attempt, which is potentially repeated until success or until the user scrolls, due to the fact that relevant content indicated by the [scroll position data](#)<sup>p1005</sup> might take some time to load from the network.*

#### Note

*Scroll restoration might be affected by scroll anchoring. [\[CSSSCROLLANCHORING\]](#)<sup>p1477</sup>*

## 7.5 Document lifecycle <sup>p10</sup>

56

### 7.5.1 Shared document creation infrastructure <sup>p10</sup>

56

When loading a document using one of the below algorithms, we use the following steps to **create and initialize a Document object**, given a [type](#) type, [content type](#) contentType, and [navigation params](#)<sup>p1013</sup> navigationParams:

#### Note

[Document](#)<sup>p130</sup> objects are also created when [creating a new browsing context and document](#)<sup>p999</sup>; such [initial about:blank](#)<sup>p131</sup> [Document](#)<sup>p130</sup> are never created by this algorithm. Also, [browsing context](#)<sup>p999</sup>-less [Document](#)<sup>p130</sup> objects can be created via various APIs, such as [document.implementation.createHTMLDocument\(\)](#).

1. Let browsingContext be navigationParams's [navigable](#)<sup>p1013</sup>'s [active browsing context](#)<sup>p989</sup>.
2. Set browsingContext to the result of the [obtaining a browsing context to use for a navigation response](#)<sup>p907</sup> given browsingContext, navigationParams's [final sandboxing flag set](#)<sup>p1013</sup>, navigationParams's [cross-origin opener policy](#)<sup>p1013</sup>, and navigationParams's [COOP enforcement result](#)<sup>p1013</sup>.

#### Note

*This can result in a [browsing context group switch](#)<sup>p905</sup>, in which case browsingContext will be a [newly-created](#)<sup>p999</sup> [browsing context](#)<sup>p998</sup> instead of being navigationParams's [navigable](#)<sup>p1013</sup>'s [active browsing context](#)<sup>p989</sup>. In such a case, the created [Window](#)<sup>p922</sup>, [Document](#)<sup>p130</sup>, and [agent](#) will not end up being used; because the created [Document](#)<sup>p130</sup>'s [origin](#) is [opaque](#)<sup>p898</sup>, we will end up creating a new [agent](#) and [Window](#)<sup>p922</sup> later in this algorithm<sup>p1057</sup> to go along with the new [Document](#)<sup>p130</sup>.*

3. Let permissionsPolicy be the result of [creating a permissions policy from a response](#) given navigationParams's [navigable](#)<sup>p1013</sup>'s [container](#)<sup>p991</sup>, navigationParams's [origin](#)<sup>p1013</sup>, and navigationParams's [response](#)<sup>p1013</sup>. [\[PERMISSIONSPOLICY\]](#)<sup>p1480</sup>

#### Note

*The [creating a permissions policy from a response](#) algorithm makes use of the passed [origin](#)<sup>p898</sup>. If [document.domain](#)<sup>p901</sup> has been used for navigationParams's [navigable](#)<sup>p1013</sup>'s [container document](#)<sup>p992</sup>, then its [origin](#) cannot be [same origin-domain](#)<sup>p899</sup> with the passed origin, because these steps run before the document is created, so it cannot itself yet have used [document.domain](#)<sup>p901</sup>. Note that this means that Permissions Policy checks are less permissive compared to doing a [same origin](#)<sup>p899</sup> check instead.*

*See below for some examples of this in action.*

4. Let creationURL be navigationParams's [response](#)<sup>p1013</sup>'s [URL](#).
5. If navigationParams's [request](#)<sup>p1013</sup> is non-null, then set creationURL to navigationParams's [request](#)<sup>p1013</sup>'s [current URL](#).
6. Let window be null.
7. If browsingContext's [active document](#)<sup>p998</sup>'s [is initial about:blank](#)<sup>p131</sup> is true, and browsingContext's [active document](#)<sup>p998</sup>'s [origin](#) is [same origin-domain](#)<sup>p899</sup> with navigationParams's [origin](#)<sup>p1013</sup>, then set window to browsingContext's [active window](#)<sup>p998</sup>.

## Note

This means that both the [initial about:blank](#)<sup>p131</sup> [Document](#)<sup>p130</sup>, and the new [Document](#)<sup>p130</sup> that is about to be created, will share the same [Window](#)<sup>p922</sup> object.

8. Otherwise:

1. Let *oacHeader* be the result of [getting a structured field value](#) given ``Origin-Agent-Cluster``<sup>p902</sup> and "item" from *navigationParams*'s [response](#)<sup>p1013</sup>'s [header list](#).
2. Let *requestsOAC* be true if *oacHeader* is not null and *oacHeader*[0] is the [boolean](#) true; otherwise false.
3. If *navigationParams*'s [reserved environment](#)<sup>p1013</sup> is a [non-secure context](#)<sup>p1084</sup>, then set *requestsOAC* to false.
4. Let *agent* be the result of [obtaining a similar-origin window agent](#)<sup>p1073</sup> given *navigationParams*'s [origin](#)<sup>p1013</sup>, *browsingContext*'s [group](#)<sup>p1002</sup>, and *requestsOAC*.
5. Let *realmExecutionContext* be the result of [creating a new realm](#)<sup>p1077</sup> given *agent* and the following customizations:
  - For the global object, create a new [Window](#)<sup>p922</sup> object.
  - For the global **this** binding, use *browsingContext*'s [WindowProxy](#)<sup>p934</sup> object.
6. Set *window* to the [global object](#)<sup>p1077</sup> of *realmExecutionContext*'s Realm component.
7. Let *topLevelCreationURL* be *creationURL*.
8. Let *topLevelOrigin* be *navigationParams*'s [origin](#)<sup>p1013</sup>.
9. If *navigable*'s [container](#)<sup>p991</sup> is not null, then:
  1. Let *parentEnvironment* be *navigable*'s [container](#)<sup>p991</sup>'s [relevant settings object](#)<sup>p1083</sup>.
  2. Set *topLevelCreationURL* to *parentEnvironment*'s [top-level creation URL](#)<sup>p1075</sup>.
  3. Set *topLevelOrigin* to *parentEnvironment*'s [top-level origin](#)<sup>p1076</sup>.
10. [Set up a window environment settings object](#)<sup>p933</sup> with *creationURL*, *realmExecutionContext*, *navigationParams*'s [reserved environment](#)<sup>p1013</sup>, *topLevelCreationURL*, and *topLevelOrigin*.

## Note

This is the usual case, where the new [Document](#)<sup>p130</sup> we're about to create gets a new [Window](#)<sup>p922</sup> to go along with it.

9. Let *loadTimingInfo* be a new [document load timing info](#)<sup>p134</sup> with its [navigation start time](#)<sup>p134</sup> set to *navigationParams*'s [response](#)<sup>p1013</sup>'s [timing info](#)'s [start time](#).
10. Let *document* be a new [Document](#)<sup>p130</sup>, with
  - [type](#)  
*type*
  - [content type](#)  
*contentType*
  - [origin](#)  
*navigationParams*'s [origin](#)<sup>p1013</sup>
  - [browsing context](#)<sup>p999</sup>  
*browsingContext*
  - [policy container](#)<sup>p131</sup>  
*navigationParams*'s [policy container](#)<sup>p1013</sup>
  - [permissions policy](#)<sup>p131</sup>  
*permissionsPolicy*
  - [active sandboxing flag set](#)<sup>p917</sup>  
*navigationParams*'s [final sandboxing flag set](#)<sup>p1013</sup>
  - [opener policy](#)<sup>p131</sup>  
*navigationParams*'s [cross-origin opener policy](#)<sup>p1013</sup>
  - [load timing info](#)<sup>p134</sup>  
*loadTimingInfo*
  - [was created via cross-origin redirects](#)<sup>p134</sup>  
*navigationParams*'s [response](#)<sup>p1013</sup>'s [has cross-origin redirects](#)

during-loading navigation ID for WebDriver BiDi<sup>p131</sup>

navigationParams's about base URL<sup>p1013</sup>

allow declarative shadow roots

true

11. Set window's [associated Document](#)<sup>p923</sup> to document.
12. [Run CSP initialization for a Document](#) given document. [\[CSP\]](#)<sup>p1476</sup>
13. If navigationParams's [request](#)<sup>p1013</sup> is non-null, then:
  1. Set document's [referrer](#)<sup>p130</sup> to the empty string.
  2. Let referrer be navigationParams's [request](#)<sup>p1013</sup>'s [referrer](#).
  3. If referrer is a [URL record](#), then set document's [referrer](#)<sup>p130</sup> to the [serialization](#) of referrer.

#### Note

Per Fetch, referrer will be either a [URL record](#) or "no-referrer" at this point.

14. If navigationParams's [fetch controller](#)<sup>p1013</sup> is not null, then:
  1. Let fullTimingInfo be the result of [extracting the full timing info](#) from navigationParams's [fetch controller](#)<sup>p1013</sup>.
  2. Let redirectCount be 0 if navigationParams's [response](#)<sup>p1013</sup>'s [has cross-origin redirects](#) is true; otherwise navigationParams's [request](#)<sup>p1013</sup>'s [redirect count](#).
  3. [Create the navigation timing entry](#) for document, given fullTimingInfo, redirectCount, navigationTimingType, navigationParams's [response](#)<sup>p1013</sup>'s [service worker timing info](#), and navigationParams's [response](#)<sup>p1013</sup>'s [body info](#).
15. [Create the navigation timing entry](#) for document, with navigationParams's [response](#)<sup>p1013</sup>'s [timing info](#), redirectCount, navigationParams's [navigation timing type](#)<sup>p1013</sup>, and navigationParams's [response](#)<sup>p1013</sup>'s [service worker timing info](#).
16. If navigationParams's [response](#)<sup>p1013</sup> has a [Refresh](#)<sup>p1069</sup> header, then:
  1. Let value be the [isomorphic decoding](#) of the value of the header.
  2. Run the [shared declarative refresh steps](#)<sup>p197</sup> with document and value.

We do not currently have a spec for how to handle multiple [Refresh](#)<sup>p1069</sup> headers. This is tracked as [issue #2900](#).

17. If navigationParams's [commit early hints](#)<sup>p1013</sup> is not null, then call navigationParams's [commit early hints](#)<sup>p1013</sup> with document.
18. [Process link headers](#)<sup>p186</sup> given document, navigationParams's [response](#)<sup>p1013</sup>, and "pre-media".
19. Return document.

#### Example

In this example, the child document is not allowed to use [PaymentRequest](#), despite being [same origin-domain](#)<sup>p899</sup> at the time the child document tries to use it. At the time the child document is initialized, only the parent document has set [document.domain](#)<sup>p901</sup>, and the child document has not.

```
<!-- https://foo.example.com/a.html -->
<!doctype html>
<script>
document.domain = 'example.com';
</script>
<iframe src=b.html></iframe>
```

```

<!-- https://bar.example.com/b.html -->
<!doctype html>
<script>
document.domain = 'example.com'; // This happens after the document is initialized
new PaymentRequest(...); // Not allowed to use
</script>

```

#### Example

In this example, the child document *is* allowed to use `PaymentRequest`, despite not being [same origin-domain](#)<sup>p899</sup> at the time the child document tries to use it. At the time the child document is initialized, none of the documents have set `document.domain`<sup>p901</sup> yet so [same origin-domain](#)<sup>p899</sup> falls back to a normal [same origin](#)<sup>p899</sup> check.

```

<!-- https://example.com/a.html -->
<!doctype html>
<iframe src=b.html></iframe>
<!-- The child document is now initialized, before the script below is run. -->
<script>
document.domain = 'example.com';
</script>

<!-- https://example.com/b.html -->
<!doctype html>
<script>
new PaymentRequest(...); // Allowed to use
</script>

```

To **populate with `html/head/body`** given a [Document](#)<sup>p130</sup> *document*:

1. Let *html* be the result of [creating an element](#) given *document*, [html](#)<sup>p172</sup>, and the [HTML namespace](#).
2. Let *head* be the result of [creating an element](#) given *document*, [head](#)<sup>p173</sup>, and the [HTML namespace](#).
3. Let *body* be the result of [creating an element](#) given *document*, [body](#)<sup>p205</sup>, and the [HTML namespace](#).
4. [Append](#) *html* to *document*.
5. [Append](#) *head* to *html*.
6. [Append](#) *body* to *html*.

## 7.5.2 Loading HTML documents §<sup>p10</sup><sub>59</sub>

To **load an HTML document**, given [navigation\\_params](#)<sup>p1013</sup> *navigationParams*:

1. Let *document* be the result of [creating and initializing a Document object](#)<sup>p1056</sup> given "html", "text/html", and *navigationParams*.
2. If *document*'s [URL](#) is [about:blank](#)<sup>p53</sup>, then [populate with html/head/body](#)<sup>p1059</sup> given *document*.

#### Note

*This special case, where even non-initial [about:blank](#)<sup>p131</sup> [Document](#)<sup>p130</sup>s are synchronously given their element nodes, is necessary for compatible with deployed content. In other words, it is not compatible to instead go down the "otherwise" branch and feed the empty [byte sequence](#) into an [HTML parser](#)<sup>p1271</sup> to asynchronously populate *document*.*

3. Otherwise, create an [HTML parser](#)<sup>p1271</sup> and associate it with the *document*. Each [task](#)<sup>p1124</sup> that the [networking task source](#)<sup>p1134</sup> places on the [task queue](#)<sup>p1123</sup> while fetching runs must then fill the parser's [input byte stream](#)<sup>p1277</sup> with the fetched bytes and cause the [HTML parser](#)<sup>p1271</sup> to perform the appropriate processing of the input stream.

The first [task](#)<sup>p1124</sup> that the [networking task source](#)<sup>p1134</sup> places on the [task queue](#)<sup>p1123</sup> while fetching runs must [process link](#)

[headers](#)<sup>p186</sup> given *document*, *navigationParams*'s [response](#)<sup>p1013</sup>, and "media", after the task has been processed by the [HTML parser](#)<sup>p1271</sup>.

Before any script execution occurs, the user agent must wait for [scripts may run for the newly-created document](#)<sup>p1051</sup> to be true for *document*.

#### Note

The [input byte stream](#)<sup>p1277</sup> converts bytes into characters for use in the [tokenizer](#)<sup>p1290</sup>. This process relies, in part, on character encoding information found in the real [Content-Type metadata](#)<sup>p98</sup> of the resource; the computed type is not used for this purpose.

When no more bytes are available, the user agent must [queue a global task](#)<sup>p1125</sup> on the [networking task source](#)<sup>p1134</sup> given *document*'s [relevant global object](#)<sup>p1083</sup> to have the parser process the implied EOF character, which eventually causes a [load](#)<sup>p1471</sup> event to be fired.

4. Return *document*.

### 7.5.3 Loading XML documents §<sup>p10</sup> 60

When faced with displaying an XML file inline, provided [navigation params](#)<sup>p1013</sup> *navigationParams* and a string type, user agents must follow the requirements defined in *XML* and *Namespaces in XML*, *XML Media Types*, *DOM*, and other relevant specifications to [create and initialize a Document object](#)<sup>p1056</sup> *document*, given "xml", type, and *navigationParams*, and return that [Document](#)<sup>p130</sup>. They must also create a corresponding [XML parser](#)<sup>p1384</sup>. [\[XML\]](#)<sup>p1484</sup> [\[XMLNS\]](#)<sup>p1484</sup> [\[RFC7303\]](#)<sup>p1482</sup> [\[DOM\]](#)<sup>p1478</sup>

#### Note

At the time of writing, the XML specification community had not actually yet specified how XML and the DOM interact.

The first [task](#)<sup>p1124</sup> that the [networking task source](#)<sup>p1134</sup> places on the [task queue](#)<sup>p1123</sup> while fetching runs must [process link headers](#)<sup>p186</sup> given *document*, *navigationParams*'s [response](#)<sup>p1013</sup>, and "media", after the task has been processed by the [XML parser](#)<sup>p1384</sup>.

The actual HTTP headers and other metadata, not the headers as mutated or implied by the algorithms given in this specification, are the ones that must be used when determining the character encoding according to the rules given in the above specifications. Once the character encoding is established, the [document's character encoding](#) must be set to that character encoding.

Before any script execution occurs, the user agent must wait for [scripts may run for the newly-created document](#)<sup>p1051</sup> to be true for the newly-created [Document](#)<sup>p130</sup>.

Once parsing is complete, the user agent must set *document*'s [during-loading navigation ID for WebDriver BiDi](#)<sup>p131</sup> to null.

#### Note

For HTML documents this is reset when parsing is complete, after firing the load event.

Error messages from the parse process (e.g., XML namespace well-formedness errors) may be reported inline by mutating the [Document](#)<sup>p130</sup>.

### 7.5.4 Loading text documents §<sup>p10</sup> 60

To **load a text document**, given a [navigation params](#)<sup>p1013</sup> *navigationParams* and a string type:

1. Let *document* be the result of [creating and initializing a Document object](#)<sup>p1056</sup> given "html", type, and *navigationParams*.
2. Set *document*'s [parser cannot change the mode flag](#)<sup>p1325</sup> to true.
3. Set *document*'s [mode](#) to "no-quirks".
4. Create an [HTML parser](#)<sup>p1271</sup> and associate it with the *document*. Act as if the tokenizer had emitted a start tag token with the tag name "pre" followed by a single U+000A LINE FEED (LF) character, and switch the [HTML parser](#)<sup>p1271</sup>'s tokenizer to the [PLAINTEXT state](#)<sup>p1292</sup>. Each [task](#)<sup>p1124</sup> that the [networking task source](#)<sup>p1134</sup> places on the [task queue](#)<sup>p1123</sup> while fetching runs

must then fill the parser's [input byte stream](#)<sup>p1277</sup> with the fetched bytes and cause the [HTML parser](#)<sup>p1271</sup> to perform the appropriate processing of the input stream.

*document*'s [encoding](#) must be set to the character encoding used to decode the document during parsing.

The first [task](#)<sup>p1124</sup> that the [networking task source](#)<sup>p1134</sup> places on the [task queue](#)<sup>p1123</sup> while fetching runs must [process link headers](#)<sup>p186</sup> given *document*, *navigationParams*'s [response](#)<sup>p1013</sup>, and "media", after the task has been processed by the [HTML parser](#)<sup>p1271</sup>.

Before any script execution occurs, the user agent must wait for [scripts may run for the newly-created document](#)<sup>p1051</sup> to be true for *document*.

When no more bytes are available, the user agent must [queue a global task](#)<sup>p1125</sup> on the [networking task source](#)<sup>p1134</sup> given *document*'s [relevant global object](#)<sup>p1083</sup> to have the parser process the implied EOF character, which eventually causes a [load](#)<sup>p1471</sup> event to be fired.

5. User agents may add content to the [head](#)<sup>p173</sup> element of *document*, e.g., linking to a style sheet, providing script, or giving the document a [title](#)<sup>p174</sup>.

#### Note

*In particular, if the user agent supports the Format=Flowed feature of RFC 3676 then the user agent would need to apply extra styling to cause the text to wrap correctly and to handle the quoting feature. This could be performed using, e.g., a CSS extension.*

6. Return *document*.

The rules for how to convert the bytes of the plain text document into actual characters, and the rules for actually rendering the text to the user, are defined by the specifications for the [computed MIME type](#) of the resource (i.e., *type*).

## 7.5.5 Loading [multipart/x-mixed-replace](#)<sup>p1445</sup> documents §<sup>p10</sup><sub>61</sub>

To **load a [multipart/x-mixed-replace](#) document**, given [navigation params](#)<sup>p1013</sup> *navigationParams*, [source snapshot params](#)<sup>p1012</sup> *sourceSnapshotParams*, and [origin](#)<sup>p898</sup> *initiatorOrigin*:

1. Parse *navigationParams*'s [response](#)<sup>p1013</sup>'s [body](#) using the rules for multipart types. [\[RFC2046\]](#)<sup>p1481</sup>
2. Let *firstPartNavigationParams* be a copy of *navigationParams*.
3. Set *firstPartNavigationParams*'s [response](#)<sup>p1013</sup> to a new [response](#) representing the first part of *navigationParams*'s [response](#)<sup>p1013</sup>'s [body](#)'s multipart stream.
4. Let *document* be the result of [loading a document](#)<sup>p1039</sup> given *firstPartNavigationParams*, *sourceSnapshotParams*, and *initiatorOrigin*.

For each additional body part obtained from *navigationParams*'s [response](#)<sup>p1013</sup>, the user agent must [navigate](#)<sup>p1014</sup> *document*'s [node navigable](#)<sup>p989</sup> to *navigationParams*'s [request](#)<sup>p1013</sup>'s [URL](#), using *document*, with [response](#)<sup>p1014</sup> set to *navigationParams*'s [response](#)<sup>p1013</sup> and [historyHandling](#)<sup>p1014</sup> set to "[replace](#)<sup>p1014</sup>".

5. Return *document*.

For the purposes of algorithms processing these body parts as if they were complete stand-alone resources, the user agent must act as if there were no more bytes for those resources whenever the boundary following the body part is reached.

#### Note

*Thus, [load](#)<sup>p1471</sup> events (and for that matter [unload](#)<sup>p1472</sup> events) do fire for each body part loaded.*

## 7.5.6 Loading media documents §<sup>p10</sup><sub>61</sub>

To **load a media document**, given *navigationParams* and a string *type*:

1. Let *document* be the result of [creating and initializing a Document object](#)<sup>p1056</sup> given "html", *type*, and *navigationParams*.

2. Set *document*'s [mode](#) to "no-quirks".
3. [Populate with html/head/body](#)<sup>p1059</sup> given *document*.
4. Append an element *host element* for the media, as described below, to the [body](#)<sup>p205</sup> element.
5. Set the appropriate attribute of the element *host element*, as described below, to the address of the image, video, or audio resource.
6. User agents may add content to the [head](#)<sup>p173</sup> element of *document*, or attributes to *host element*, e.g., to link to a style sheet, to provide a script, to give the document a [title](#)<sup>p174</sup>, or to make the media [autoplay](#)<sup>p435</sup>.
7. [Process link headers](#)<sup>p186</sup> given *document*, *navigationParams*'s [response](#)<sup>p1013</sup>, and "media".
8. Act as if the user agent had [stopped parsing](#)<sup>p1358</sup> *document*.
9. Return *document*.

The element *host element* to create for the media is the element given in the table below in the second cell of the row whose first cell describes the media. The appropriate attribute to set is the one given by the third cell in that same row.

Type of media	Element for the media	Appropriate attribute
Image	<a href="#">img</a> <sup>p346</sup>	<a href="#">src</a> <sup>p347</sup>
Video	<a href="#">video</a> <sup>p406</sup>	<a href="#">src</a> <sup>p416</sup>
Audio	<a href="#">audio</a> <sup>p410</sup>	<a href="#">src</a> <sup>p416</sup>

Before any script execution occurs, the user agent must wait for [scripts may run for the newly-created document](#)<sup>p1051</sup> to be true for the [Document](#)<sup>p130</sup>.

**7.5.7 Loading a document for inline content that doesn't have a DOM** §<sup>p10</sup><sub>62</sub>

When the user agent is to create a document to display a user agent page or PDF viewer inline, provided a [navigable](#)<sup>p989</sup> *navigable*, a [navigation ID](#)<sup>p1014</sup> *navigationId*, a [NavigationTimingType](#) *navTimingType*, the user agent should:

1. Let *origin* be a new [opaque origin](#)<sup>p898</sup>.
2. Let *coop* be a new [opener policy](#)<sup>p904</sup>.
3. Let *coopEnforcementResult* be a new [opener policy enforcement result](#)<sup>p906</sup> with
  - [uri](#)<sup>p906</sup>  
*response*'s [URL](#)
  - [origin](#)<sup>p906</sup>  
*origin*
  - [opener policy](#)<sup>p906</sup>  
*coop*
4. Let *navigationParams* be a new [navigation params](#)<sup>p1013</sup> with
  - [id](#)<sup>p1013</sup>  
*navigationId*
  - [navigable](#)<sup>p1013</sup>  
*navigable*
  - [request](#)<sup>p1013</sup>  
null
  - [response](#)<sup>p1013</sup>  
a new [response](#)
  - [origin](#)<sup>p1013</sup>  
*origin*
  - [fetch controller](#)<sup>p1013</sup>  
null
  - [commit early hints](#)<sup>p1013</sup>  
null

#### **COOP enforcement result**<sup>p1013</sup>

`coopEnforcementResult`

#### **reserved environment**<sup>p1013</sup>

`null`

#### **policy container**<sup>p1013</sup>

a new `policy container`<sup>p917</sup>

#### **final sandboxing flag set**<sup>p1013</sup>

an empty set

#### **opener policy**<sup>p1013</sup>

`coop`

#### **navigation timing type**<sup>p1013</sup>

`navTimingType`

#### **about base URL**<sup>p1013</sup>

`null`

5. Let *document* be the result of [creating and initializing a Document object](#)<sup>p1056</sup> given "html", "text/html", and *navigationParams*.
6. Either associate *document* with a custom rendering that is not rendered using the normal [Document](#)<sup>p130</sup> rendering rules, or mutate *document* until it represents the content the user agent wants to render.
7. Return *document*.

#### Note

Because we ensure the resulting [Document](#)<sup>p130</sup>'s *origin* is [opaque](#)<sup>p898</sup>, and the resulting [Document](#)<sup>p130</sup> cannot run script with access to the DOM, the existence and properties of this [Document](#)<sup>p130</sup> are not observable to web developer code. This means that most of the above values, e.g., the [text/html](#)<sup>p1444</sup> type, do not matter. Similarly, most of the items in *navigationParams* don't have any observable effect, besides preventing the [Document-creation algorithm](#)<sup>p1056</sup> from getting confused, and so are set to default values.

Once the page has been set up, the user agent must act as if it had [stopped parsing](#)<sup>p1358</sup>.

### 7.5.8 Finishing the loading process <sup>p10</sup><sub>63</sub>

A [Document](#)<sup>p130</sup> has a **completely loaded time** (a time or null), which is initially null.

A [Document](#)<sup>p130</sup> is considered **completely loaded** if its [completely loaded time](#)<sup>p1063</sup> is non-null.

To **completely finish loading** a [Document](#)<sup>p130</sup> document:

1. **Assert:** *document*'s [browsing context](#)<sup>p999</sup> is non-null.
2. Set *document*'s [completely loaded time](#)<sup>p1063</sup> to the current time.
3. Let *container* be *document*'s [node navigable](#)<sup>p989</sup>'s [container](#)<sup>p991</sup>.

#### Note

This will be null in the case where document is the [initial about:blank](#)<sup>p131</sup> [Document](#)<sup>p130</sup> in a [frame](#)<sup>p1433</sup> or [iframe](#)<sup>p390</sup>, since at the point of [browsing context creation](#)<sup>p999</sup> which calls this algorithm, the container relationship has not yet been established. (That happens in a subsequent step of [create a new child navigable](#)<sup>p992</sup>.)

The consequence of this is that the following steps do nothing, i.e., we do not fire an asynchronous [load](#)<sup>p1471</sup> event on the container element for such cases. Instead, a synchronous [load](#)<sup>p1471</sup> event is fired in a special initial-insertion case when [processing the iframe attributes](#)<sup>p393</sup>.

4. If *container* is an [iframe](#)<sup>p390</sup> element, then [queue an element task](#)<sup>p1125</sup> on the [DOM manipulation task source](#)<sup>p1134</sup> given *container* to run the [iframe load event steps](#)<sup>p394</sup> given *container*.
5. Otherwise, if *container* is non-null, then [queue an element task](#)<sup>p1125</sup> on the [DOM manipulation task source](#)<sup>p1134</sup> given *container* to [fire an event](#) named [load](#)<sup>p1471</sup> at *container*.

## 7.5.9 Unloading documents <sup>§<sup>p10</sup></sup> <sup>64</sup>

A [Document](#)<sup>p130</sup> has a **salvageable** state, which must initially be true, and a **page showing** flag, which must initially be false. The [page showing](#)<sup>p1064</sup> flag is used to ensure that scripts receive [pageshow](#)<sup>p1472</sup> and [pagehide](#)<sup>p1472</sup> events in a consistent manner (e.g. that they never receive two [pagehide](#)<sup>p1472</sup> events in a row without an intervening [pageshow](#)<sup>p1472</sup>, or vice versa).

A [Document](#)<sup>p130</sup> has a [DOMHighResTimeStamp](#) **suspension time**, initially 0.

A [Document](#)<sup>p130</sup> has a [list](#) of **suspended timer handles**, initially empty.

[Event loops](#)<sup>p1123</sup> have a **termination nesting level** counter, which must initially be 0.

[Document](#)<sup>p130</sup> objects have an **unload counter**, which is used to ignore certain operations while the below algorithms run. Initially, the counter must be set to zero.

To **unload** a [Document](#)<sup>p130</sup> *oldDocument*, given an optional [Document](#)<sup>p130</sup> *newDocument*:

1. **Assert**: this is running as part of a [task](#)<sup>p1124</sup> queued on *oldDocument*'s [relevant agent](#)<sup>p1073</sup>'s [event loop](#)<sup>p1123</sup>.
2. Let *unloadTimingInfo* be a new [document unload timing info](#)<sup>p134</sup>.
3. If *newDocument* is not given, then set *unloadTimingInfo* to null.

### Note

*In this case there is no new document that needs to know about how long it took oldDocument to unload.*

4. Otherwise, if *newDocument*'s [event loop](#)<sup>p1123</sup> is not *oldDocument*'s [event loop](#)<sup>p1123</sup>, then the user agent may be [unloading](#)<sup>p1064</sup> *oldDocument* [in parallel](#)<sup>p43</sup>. In that case, the user agent should set *unloadTimingInfo* to null.

### Note

*In this case newDocument's loading is not impacted by how long it takes to unload oldDocument, so it would be meaningless to communicate that timing info.*

5. Let *intendToKeepInBfcache* be true if the user agent intends to keep *oldDocument* alive in a [session history entry](#)<sup>p1005</sup>, such that it can later be [used for history traversal](#)<sup>p1006</sup>.

This must be false if *oldDocument* is not [salvageable](#)<sup>p1064</sup>, or if there are any descendants of *oldDocument* which the user agent does not intend to keep alive in the same way (including due to their lack of [salvageability](#)<sup>p1064</sup>).

6. Let *eventLoop* be *oldDocument*'s [relevant agent](#)<sup>p1073</sup>'s [event loop](#)<sup>p1123</sup>.
7. Increase *eventLoop*'s [termination nesting level](#)<sup>p1064</sup> by 1.
8. Increase *oldDocument*'s [unload counter](#)<sup>p1064</sup> by 1.
9. If *intendToKeepInBfcache* is false, then set *oldDocument*'s [salvageable](#)<sup>p1064</sup> state to false.
10. If *oldDocument*'s [page showing](#)<sup>p1064</sup> is true:
  1. Set *oldDocument*'s [page showing](#)<sup>p1064</sup> to false.
  2. **Fire a page transition event**<sup>p983</sup> named [pagehide](#)<sup>p1472</sup> at *oldDocument*'s [relevant global object](#)<sup>p1083</sup> with *oldDocument*'s [salvageable](#)<sup>p1064</sup> state.
  3. **Update the visibility state**<sup>p826</sup> of *oldDocument* to "hidden".
11. If *unloadTimingInfo* is not null, then set *unloadTimingInfo*'s [unload event start time](#)<sup>p134</sup> to the [current high resolution time](#) given *newDocument*'s [relevant global object](#)<sup>p1083</sup>, [coarsened](#) given *oldDocument*'s [relevant settings object](#)<sup>p1083</sup>'s [cross-origin isolated capability](#)<sup>p1076</sup>.
12. If *oldDocument*'s [salvageable](#)<sup>p1064</sup> state is false, then **fire an event** named [unload](#)<sup>p1472</sup> at *oldDocument*'s [relevant global object](#)<sup>p1083</sup>, with *legacy target override flag* set.
13. If *unloadTimingInfo* is not null, then set *unloadTimingInfo*'s [unload event end time](#)<sup>p134</sup> to the [current high resolution time](#) given *newDocument*'s [relevant global object](#)<sup>p1083</sup>, [coarsened](#) given *oldDocument*'s [relevant settings object](#)<sup>p1083</sup>'s [cross-origin isolated capability](#)<sup>p1076</sup>.
14. Decrease *eventLoop*'s [termination nesting level](#)<sup>p1064</sup> by 1.

15. Set *oldDocument*'s [suspension time](#)<sup>p1064</sup> to the [current high resolution time](#) given *document*'s [relevant global object](#)<sup>p1083</sup>.
16. Set *oldDocument*'s [suspended timer handles](#)<sup>p1064</sup> to the result of [getting the keys](#) for the [map of active timers](#)<sup>p1164</sup>.
17. Set *oldDocument*'s [has been scrolled by the user](#)<sup>p1055</sup> to false.
18. Run any [unloading document cleanup steps](#)<sup>p1065</sup> for *oldDocument* that are defined by this specification and [other applicable specifications](#)<sup>p73</sup>.
19. If *oldDocument*'s [node navigable](#)<sup>p989</sup> is a [top-level traversable](#)<sup>p990</sup>, [build not restored reasons for a top-level traversable and its descendants](#)<sup>p1053</sup> given *oldDocument*'s [node navigable](#)<sup>p989</sup>.
20. If *oldDocument*'s [salvageable](#)<sup>p1064</sup> state is false, then [destroy](#)<sup>p1066</sup> *oldDocument*.
21. Decrease *oldDocument*'s [unload counter](#)<sup>p1064</sup> by 1.
22. If *newDocument* is given, *newDocument*'s [was created via cross-origin redirects](#)<sup>p134</sup> is false, and *newDocument*'s [origin](#) is the [same](#)<sup>p899</sup> as *oldDocument*'s [origin](#), then set *newDocument*'s [previous document unload timing](#)<sup>p134</sup> to [unloadTimingInfo](#).

To **unload a document and its descendants**, given a [Document](#)<sup>p130</sup> *document*, an optional [Document](#)<sup>p130</sup>-or-null *newDocument* (default null), an optional set of steps *afterAllUnloads*, and an optional set of steps *firePageSwapSteps*:

1. [Assert](#): this is running within *document*'s [node navigable](#)<sup>p989</sup>'s [traversable navigable](#)<sup>p990</sup>'s [session history traversal queue](#)<sup>p990</sup>.
2. Let *childNavigables* be *document*'s [child navigables](#)<sup>p992</sup>.
3. Let *numberUnloaded* be 0.
4. [For each](#) *childNavigable* of *childNavigables*'s in what order?, [queue a global task](#)<sup>p1125</sup> on the [navigation and traversal task source](#)<sup>p1134</sup> given *childNavigable*'s [active window](#)<sup>p989</sup> to perform the following steps:
  1. Let *incrementUnloaded* be an algorithm step which increments *numberUnloaded*.
  2. [Unload a document and its descendants](#)<sup>p1065</sup> given *childNavigable*'s [active document](#)<sup>p989</sup>, null, and *incrementUnloaded*.
5. Wait until *numberUnloaded* equals *childNavigable*'s [size](#).
6. [Queue a global task](#)<sup>p1125</sup> on the [navigation and traversal task source](#)<sup>p1134</sup> given *document*'s [relevant global object](#)<sup>p1083</sup> to perform the following steps:
  1. If *firePageSwapSteps* is given, then run *firePageSwapSteps*.
  2. [Unload](#)<sup>p1064</sup> *document*, passing along *newDocument* if it is not null.
  3. If *afterAllUnloads* was given, then run it.

This specification defines the following **unloading document cleanup steps**. Other specifications can define more. Given a [Document](#)<sup>p130</sup> *document*:

1. Let *window* be *document*'s [relevant global object](#)<sup>p1083</sup>.
2. For each [WebSocket](#) object *webSocket* whose [relevant global object](#)<sup>p1083</sup> is *window*, [make disappear](#) *webSocket*.  
If this affected any [WebSocket](#) objects, then [make document unsalvageable](#)<sup>p1052</sup> given *document* and ["websocket"](#)<sup>p985</sup>.
3. For each [WebTransport](#) object *transport* whose [relevant global object](#)<sup>p1083</sup> is *window*, run the [context cleanup steps](#) given *transport*.
4. If *document*'s [salvageable](#)<sup>p1064</sup> state is false, then:
  1. For each [EventSource](#)<sup>p1191</sup> object *eventSource* whose [relevant global object](#)<sup>p1083</sup> is equal to *window*, [forcibly close](#)<sup>p1198</sup> *eventSource*.
  2. [Clear](#) *window*'s [map of active timers](#)<sup>p1164</sup>.

It would be better if specification authors sent a pull request to add calls from here into their specifications directly, instead of using the [unloading document cleanup steps](#)<sup>p1065</sup> hook, to ensure well-defined cross-specification call order. As of the time of this

writing the following specifications are known to have [unloading document cleanup steps](#)<sup>p1065</sup>, which will be run in an unspecified order: [Fullscreen API](#), [Web NFC](#), [WebDriver BiDi](#), [Compute Pressure](#), [File API](#), [Media Capture and Streams](#), [Picture-in-Picture](#), [Screen Orientation](#), [Service Workers](#), [WebLocks API](#), [WebAudio API](#), [WebRTC](#). [\[FULLSCREEN\]](#)<sup>p1478</sup> [\[WEBNFC\]](#)<sup>p1484</sup> [\[WEBDRIVERBIDI\]](#)<sup>p1483</sup> [\[COMPUTEPRESSURE\]](#)<sup>p1475</sup> [\[FILEAPI\]](#)<sup>p1478</sup> [\[MEDIASTREAM\]](#)<sup>p1480</sup> [\[PICTUREINPICTURE\]](#)<sup>p1480</sup> [\[SCREENORIENTATION\]](#)<sup>p1482</sup> [\[SW\]](#)<sup>p1482</sup> [\[WEBLOCKS\]](#)<sup>p1484</sup> [\[WEBAUDIO\]](#)<sup>p1483</sup> [\[WEBRTC\]](#)<sup>p1484</sup>

[Issue #8906](#) tracks the work to make the order of these steps clear.

## 7.5.10 Destroying documents <sup>p1066</sup>

To **destroy** a [Document](#)<sup>p130</sup> *document*:

1. [Assert](#): this is running as part of a [task](#)<sup>p1124</sup> queued on *document*'s [relevant agent](#)<sup>p1073</sup>'s [event loop](#)<sup>p1123</sup>.
2. [Abort](#)<sup>p1067</sup> *document*.
3. Set *document*'s [salvageable](#)<sup>p1064</sup> state to false.
4. Let *ports* be the list of [MessagePort](#)<sup>p1205</sup>s whose [relevant global object](#)<sup>p1083</sup>'s [associated Document](#)<sup>p923</sup> is *document*.
5. For each *port* in *ports*, [disentangle](#)<sup>p1206</sup> *port*.
6. Run any [unloading document cleanup steps](#)<sup>p1065</sup> for *document* that are defined by this specification and [other applicable specifications](#)<sup>p73</sup>.
7. Remove any [tasks](#)<sup>p1124</sup> whose [document](#)<sup>p1124</sup> is *document* from any [task queue](#)<sup>p1123</sup> (without running those tasks).
8. Set *document*'s [browsing context](#)<sup>p999</sup> to null.
9. Set *document*'s [node navigable](#)<sup>p989</sup>'s [active session history entry](#)<sup>p989</sup>'s [document state](#)<sup>p1005</sup>'s [document](#)<sup>p1006</sup> to null.
10. [Remove](#) *document* from the [owner set](#)<sup>p1228</sup> of each [WorkerGlobalScope](#)<sup>p1228</sup> object whose set [contains](#) *document*.
11. [For each](#) *workletGlobalScope* in *document*'s [worklet global scopes](#)<sup>p1250</sup>, [terminate](#)<sup>p1247</sup> *workletGlobalScope*.

### Note

Even after destruction, the [Document](#)<sup>p130</sup> object itself might still be accessible to script, in the case where we are [destroying a child navigable](#)<sup>p995</sup>.

To **destroy a document and its descendants** given a [Document](#)<sup>p130</sup> *document* and an optional set of steps *afterAllDestruction*, perform the following steps [in parallel](#)<sup>p43</sup>:

1. If *document* is not [fully active](#)<sup>p1003</sup>, then:
  1. Let *reason* be a string from [user-agent specific blocking reasons](#)<sup>p985</sup>. If none apply, then let *reason* be "[masked](#)<sup>p985</sup>".
  2. [Make document unsalvageable](#)<sup>p1052</sup> given *document* and *reason*.
  3. If *document*'s [node navigable](#)<sup>p989</sup> is a [top-level traversable](#)<sup>p990</sup>, [build not restored reasons for a top-level traversable and its descendants](#)<sup>p1053</sup> given *document*'s [node navigable](#)<sup>p989</sup>.
2. Let *childNavigables* be *document*'s [child navigables](#)<sup>p992</sup>.
3. Let *numberDestroyed* be 0.
4. [For each](#) *childNavigable* of *childNavigables*'s [in what order?](#), [queue a global task](#)<sup>p1125</sup> on the [navigation and traversal task source](#)<sup>p1134</sup> given *childNavigable*'s [active window](#)<sup>p989</sup> to perform the following steps:
  1. Let *incrementDestroyed* be an algorithm step which increments *numberDestroyed*.
  2. [Destroy a document and its descendants](#)<sup>p1066</sup> given *childNavigable*'s [active document](#)<sup>p989</sup> and *incrementDestroyed*.
5. Wait until *numberDestroyed* equals *childNavigable*'s [size](#).
6. [Queue a global task](#)<sup>p1125</sup> on the [navigation and traversal task source](#)<sup>p1134</sup> given *document*'s [relevant global object](#)<sup>p1083</sup> to

perform the following steps:

1. [Destroy<sup>p1066</sup>](#) document.
2. If *afterAllDestruction* was given, then run it.

### 7.5.11 Aborting a document load <sup>p10</sup><sub>67</sub>

To **abort** a [Document<sup>p130</sup>](#) document:

1. [Assert](#): this is running as part of a [task<sup>p1124</sup>](#) queued on document's [relevant agent<sup>p1073</sup>](#)'s [event loop<sup>p1123</sup>](#).
2. Cancel any instances of the [fetch](#) algorithm in the context of *document*, discarding any [tasks<sup>p1124</sup>](#) [queued<sup>p1125</sup>](#) for them, and discarding any further data received from the network for them. If this resulted in any instances of the [fetch](#) algorithm being canceled or any [queued<sup>p1125</sup>](#) [tasks<sup>p1124</sup>](#) or any network data getting discarded, then [make document unsalvageable<sup>p1052</sup>](#) given *document* and "[fetch<sup>p985</sup>](#)".
3. If document's [during-loading navigation ID for WebDriver BiDi<sup>p131</sup>](#) is non-null, then:
  1. Invoke [WebDriver BiDi navigation aborted](#) with document's [browsing context<sup>p999</sup>](#), and a new [WebDriver BiDi navigation status](#) whose *id* is document's [during-loading navigation ID for WebDriver BiDi<sup>p131</sup>](#), *status* is "[canceled](#)", and *url* is document's [URL](#).
  2. Set document's [during-loading navigation ID for WebDriver BiDi<sup>p131</sup>](#) to null.
4. If document has an [active parser<sup>p134</sup>](#), then:
  1. Set document's [active parser was aborted<sup>p1150</sup>](#) to true.
  2. [Abort that parser<sup>p1359</sup>](#).
  3. Set document's [salvageable<sup>p1064</sup>](#) to false.
  4. [Make document unsalvageable<sup>p1052</sup>](#) given *document* and "[parser-aborted<sup>p985</sup>](#)".

To **abort a document and its descendants** given a [Document<sup>p130</sup>](#) document:

1. [Assert](#): this is running as part of a [task<sup>p1124</sup>](#) queued on document's [relevant agent<sup>p1073</sup>](#)'s [event loop<sup>p1123</sup>](#).
2. Let *descendantNavigables* be document's [descendant navigables<sup>p994</sup>](#).
3. [For each](#) *descendantNavigable* of *descendantNavigables* [in what order?](#), [queue a global task<sup>p1125</sup>](#) on the [navigation and traversal task source<sup>p1134</sup>](#) given *descendantNavigable*'s [active window<sup>p989</sup>](#) to perform the following steps:
  1. [Abort<sup>p1067</sup>](#) *descendantNavigable*'s [active document<sup>p989</sup>](#).
  2. If *descendantNavigable*'s [active document<sup>p989</sup>](#)'s [salvageable<sup>p1064</sup>](#) is false, then set document's [salvageable<sup>p1064</sup>](#) to false.
4. [Abort<sup>p1067</sup>](#) document.

To **stop loading** a [navigable<sup>p989</sup>](#) navigable:

1. Let *document* be *navigable*'s [active document<sup>p989</sup>](#).
2. If document's [unload counter<sup>p1064</sup>](#) is 0, and *navigable*'s [ongoing navigation<sup>p1027</sup>](#) is a [navigation ID<sup>p1014</sup>](#), then [set the ongoing navigation<sup>p1027</sup>](#) for *navigable* to null.

#### Note

This will have the effect of aborting any ongoing navigations of navigable, since at certain points during navigation, changes to the [ongoing navigation<sup>p1027</sup>](#) will cause further work to be abandoned.

3. [Abort a document and its descendants<sup>p1067</sup>](#) given *document*.

Through their [user interface<sup>p1069</sup>](#), user agents also allow stopping traversals, i.e. cases where the [ongoing navigation<sup>p1027</sup>](#) is

"traversal". The above algorithm does not account for this. (On the other hand, user agents do not allow `window.stop()` to stop traversals, so the above algorithm is correct for that caller.) See [issue #6905](#).

## 7.6 The `X-Frame-Options` header § 68

The `X-Frame-Options` HTTP response header is a legacy way of controlling whether and how a [Document](#) may be loaded inside of a [child navigable](#). It is obsoleted by the `frame-ancestors` CSP directive, which provides more granular control over the same situations. It was originally defined in *HTTP Header Field X-Frame-Options*, but the definition and processing model here supersedes that document. [\[CSP\]](#) [\[RFC7034\]](#)

### Note

*In particular, HTTP Header Field X-Frame-Options specified an `ALLOW-FROM` variant of the header, but that is not to be implemented.*

### Note

*Per the below processing model, if both a CSP `frame-ancestors` directive and an `X-Frame-Options` header are used in the same response, then `X-Frame-Options` is ignored.*

For web developers and conformance checkers, its value [ABNF](#) is:

```
X-Frame-Options = "DENY" / "SAMEORIGIN"
```

To check a navigation response's adherence to `X-Frame-Options`, given a [response](#) `response`, a [navigable](#) `navigable`, a [CSP list](#) `cspList`, and an [origin](#) `destinationOrigin`:

1. If `navigable` is not a [child navigable](#), then return true.
2. For each `policy` of `cspList`:
  1. If `policy`'s `disposition` is not "enforce", then continue.
  2. If `policy`'s `directive set` contains a `frame-ancestors` directive, then return true.
3. Let `rawXFrameOptions` be the result of [getting, decoding, and splitting](#) `X-Frame-Options` from `response`'s `header list`.
4. Let `xFrameOptions` be a new [set](#).
5. For each `value` of `rawXFrameOptions`, [append value, converted to ASCII lowercase](#), to `xFrameOptions`.
6. If `xFrameOptions`'s `size` is greater than 1, and `xFrameOptions` contains any of "deny", "allowall", or "sameorigin", then return false.

### Note

*The intention here is to block any attempts at applying `X-Frame-Options` which were trying to do something valid, but appear confused.*

### Note

*This is the only impact of the legacy `ALLOWALL` value on the processing model.*

7. If `xFrameOptions`'s `size` is greater than 1, then return true.

### Note

*This means it contains multiple invalid values, which we treat the same way as if the header was omitted entirely.*

8. If `xFrameOptions[0]` is "deny", then return false.
9. If `xFrameOptions[0]` is "sameorigin", then:
  1. Let `containerDocument` be `navigable`'s [container document](#).

2. [While](#) `containerDocument` is not null:

1. If `containerDocument`'s [origin](#) is not [same origin](#)<sup>p899</sup> with `destinationOrigin`, then return false.
2. Set `containerDocument` to `containerDocument`'s [container document](#)<sup>p992</sup>.

10. Return true.

#### Note

*If we've reached this point then we have a lone invalid value (which could potentially be one the legacy ``ALLOWALL`` or ``ALLOW-FROM`` forms). These are treated as if the header were omitted entirely.*

#### Example

The following table illustrates the processing of various values for the header, including non-conformant ones:

<code>`X-Frame-Options`</code> <sup>p1068</sup>	Valid	Result
<code>`DENY`</code>	✓	embedding disallowed
<code>`SAMEORIGIN`</code>	✓	same-origin embedding allowed
<code>`INVALID`</code>	✗	embedding allowed
<code>`ALLOWALL`</code>	✗	embedding allowed
<code>`ALLOW-FROM=https://example.com/`</code>	✗	embedding allowed (from anywhere)

#### Example

The following table illustrates how various non-conformant cases involving multiple values are processed:

<code>`X-Frame-Options`</code> <sup>p1068</sup>	Result
<code>`SAMEORIGIN, SAMEORIGIN`</code>	same-origin embedding allowed
<code>`SAMEORIGIN, DENY`</code>	embedding disallowed
<code>`SAMEORIGIN, `</code>	embedding disallowed
<code>`SAMEORIGIN, ALLOWALL`</code>	embedding disallowed
<code>`SAMEORIGIN, INVALID`</code>	embedding disallowed
<code>`ALLOWALL, INVALID`</code>	embedding disallowed
<code>`ALLOWALL, `</code>	embedding disallowed
<code>`INVALID, INVALID`</code>	embedding allowed

The same results are obtained whether the values are delivered in a single header whose value is comma-delimited, or in multiple headers.

## 7.7 The ``Refresh``<sup>p1069</sup> header §<sup>p10</sup><sub>69</sub>

The ``Refresh`` HTTP response header is the HTTP-equivalent to a [meta](#)<sup>p189</sup> element with an [http-equiv](#)<sup>p195</sup> attribute in the [Refresh state](#)<sup>p196</sup>. It takes [the same value](#)<sup>p198</sup> and works largely the same. Its processing model is detailed in [create and initialize a Document object](#)<sup>p1056</sup>.

## 7.8 Browser user interface considerations §<sup>p10</sup><sub>69</sub>

Browser user agents should provide the ability to [navigate](#)<sup>p1014</sup>, [reload](#)<sup>p1027</sup>, and [stop loading](#)<sup>p1067</sup> any [top-level traversable](#)<sup>p990</sup> in their [top-level traversable set](#)<sup>p990</sup>.

#### Example

For example, via a location bar and reload/stop button UI.

Browser user agents should provide the ability to [traverse by a delta](#)<sup>p1028</sup> any [top-level traversable](#)<sup>p990</sup> in their [top-level traversable](#)

[set](#)<sup>p990</sup>.

#### Example

For example, via back and forward buttons, possibly including long-press abilities to change the delta.

It is suggested that such user agents allow traversal by deltas greater than one, to avoid letting a page "trap" the user by stuffing the session history with spurious entries. (For example, via repeated calls to [history.pushState\(\)](#)<sup>p946</sup> or [fragment navigations](#)<sup>p1021</sup>.)

#### Note

*Some user agents have heuristics for translating a single "back" or "forward" button press into a larger delta, specifically to overcome such abuses. We are contemplating specifying these heuristics in [issue #7832](#).*

Browser user agents should offer users the ability to [create a fresh top-level traversable](#)<sup>p991</sup>, given a user-provided or user agent-determined initial [URL](#).

#### Example

For example, via a "new tab" or "new window" button.

Browser user agents should offer users the ability to arbitrarily [close](#)<sup>p995</sup> any [top-level traversable](#)<sup>p990</sup> in their [top-level traversable set](#)<sup>p990</sup>.

#### Example

For example, by clicking a "close tab" button.

Browser user agents may provide ways for the user to explicitly cause any [navigable](#)<sup>p989</sup> (not just a [top-level traversable](#)<sup>p990</sup>) to [navigate](#)<sup>p1014</sup>, [reload](#)<sup>p1027</sup>, or [stop loading](#)<sup>p1067</sup>.

#### Example

For example, via a context menu.

Browser user agents may provide the ability for users to [destroy a top-level traversable](#)<sup>p995</sup>.

#### Example

For example, by force-closing a window containing one or more such [top-level traversables](#)<sup>p990</sup>.

When a user requests a [reload](#)<sup>p1027</sup> of a [navigable](#)<sup>p989</sup> whose [active session history entry](#)<sup>p989</sup>'s [document state](#)<sup>p1005</sup>'s [resource](#)<sup>p1007</sup> is a [POST resource](#)<sup>p1007</sup>, the user agent should prompt the user to confirm the operation first, since otherwise transactions (e.g., purchases or database modifications) could be repeated.

When a user requests a [reload](#)<sup>p1027</sup> of a [navigable](#)<sup>p989</sup>, user agents may provide a mechanism for ignoring any caches when reloading.

All calls to [navigate](#)<sup>p1014</sup> initiated by the mechanisms mentioned above must have the [userInvolvement](#)<sup>p1014</sup> argument set to "[browser UI](#)<sup>p1014</sup>".

All calls to [reload](#)<sup>p1027</sup> initiated by the mechanisms mentioned above must have the [userInvolvement](#)<sup>p1027</sup> argument set to "[browser UI](#)<sup>p1014</sup>".

All calls to [traverse the history by a delta](#)<sup>p1028</sup> initiated by the mechanisms mentioned above must not pass a value for the [sourceDocument](#)<sup>p1028</sup> argument.

The above recommendations, and the data structures in this specification, are not meant to place restrictions on how user agents represent the session history to the user.

For example, although a [top-level traversable](#)<sup>p990</sup>'s [session history entries](#)<sup>p990</sup> are stored and maintained as a list, and the user agent is

recommended to give an interface for [traversing that list by a delta](#)<sup>p1028</sup>, a novel user agent could instead or in addition present a tree-like view, with each page having multiple "forward" pages that the user can choose between.

Similarly, although session history for all descendant [navigables](#)<sup>p989</sup> is stored in their [traversable navigable](#)<sup>p990</sup>, user agents could present the user with a more nuanced per-[navigable](#)<sup>p989</sup> view of the session history.

Browser user agents may use a [top-level browsing context](#)<sup>p1001</sup>'s [is popup](#)<sup>p998</sup> boolean for the following purposes:

- Deciding whether or not to provide a minimal web browser user interface for the corresponding [top-level traversable](#)<sup>p990</sup>.
- Performing the optional steps in [set up browsing context features](#).

In both cases user agents might additionally incorporate user preferences, or present a choice as to whether to go down the popup route.

User agents that provides a minimal user interface for such popups are encouraged to not hide the browser's location bar.

## 8 Web application APIs §<sup>p10</sup><sub>72</sub>

### 8.1 Scripting §<sup>p10</sup><sub>72</sub>

#### 8.1.1 Introduction §<sup>p10</sup><sub>72</sub>

Various mechanisms can cause author-provided executable code to run in the context of a document. These mechanisms include, but are probably not limited to:

- Processing of `script`<sup>p652</sup> elements.
- Navigating to `javascript: URLs`<sup>p1019</sup>.
- Event handlers, whether registered through the DOM using `addEventListener()`, by explicit [event handler content attributes](#)<sup>p1138</sup>, by [event handler IDL attributes](#)<sup>p1137</sup>, or otherwise.
- Processing of technologies like SVG that have their own scripting features.

#### 8.1.2 Agents and agent clusters §<sup>p10</sup><sub>72</sub>

##### 8.1.2.1 Integration with the JavaScript agent formalism §<sup>p10</sup><sub>72</sub>

JavaScript defines the concept of an [agent](#). This section gives the mapping of that language-level concept on to the web platform.

##### Note

Conceptually, the [agent](#) concept is an architecture-independent, idealized "thread" in which JavaScript code runs. Such code can involve multiple [globals/realms](#)<sup>p1077</sup> that can synchronously access each other, and thus needs to run in a single execution thread.

Two [Window](#)<sup>p922</sup> objects having the same [agent](#) does not indicate they can directly access all objects created in each other's realms. They would have to be [same origin-domain](#)<sup>p899</sup>; see [IsPlatformObjectSameOrigin](#)<sup>p920</sup>.

The following types of agents exist on the web platform:

##### **Similar-origin window agent**

Contains various [Window](#)<sup>p922</sup> objects which can potentially reach each other, either directly or by using [document.domain](#)<sup>p901</sup>.

If the encompassing [agent cluster](#)'s [is origin-keyed](#)<sup>p1073</sup> is true, then all the [Window](#)<sup>p922</sup> objects will be [same origin](#)<sup>p899</sup>, can reach each other directly, and [document.domain](#)<sup>p901</sup> will no-op.

##### Note

Two [Window](#)<sup>p922</sup> objects that are [same origin](#)<sup>p899</sup> can be in different [similar-origin window agents](#)<sup>p1072</sup>, for instance if they are each in their own [browsing context group](#)<sup>p1002</sup>.

##### **Dedicated worker agent**

Contains a single [DedicatedWorkerGlobalScope](#)<sup>p1230</sup>.

##### **Shared worker agent**

Contains a single [SharedWorkerGlobalScope](#)<sup>p1230</sup>.

##### **Service worker agent**

Contains a single [ServiceWorkerGlobalScope](#).

##### **Worklet agent**

Contains a single [WorkletGlobalScope](#)<sup>p1245</sup> object.

## Note

Although a given worklet can have multiple realms, each such realm needs its own agent, as each realm can be executing code independently and at the same time as the others.

Only [shared](#)<sup>p1072</sup> and [dedicated worker agents](#)<sup>p1072</sup> allow the use of JavaScript [Atomics](#) APIs to potentially [block](#).

To **create an agent**, given a boolean *canBlock*:

1. Let *signifier* be a new unique internal value.
2. Let *candidateExecution* be a new [candidate execution](#).
3. Let *agent* be a new [agent](#) whose `[[CanBlock]]` is *canBlock*, `[[Signifier]]` is *signifier*, `[[CandidateExecution]]` is *candidateExecution*, and `[[IsLockFree1]]`, `[[IsLockFree2]]`, and `[[LittleEndian]]` are set at the implementation's discretion.
4. Set *agent*'s [event loop](#)<sup>p1123</sup> to a new [event loop](#)<sup>p1123</sup>.
5. Return *agent*.

For a [realm](#) *realm*, the [agent](#) whose `[[Signifier]]` is *realm*.`[[AgentSignifier]]` is **the realm's agent**.

The **relevant agent** for a [platform object](#) *platformObject* is *platformObject*'s [relevant realm](#)<sup>p1083</sup>'s [agent](#)<sup>p1073</sup>.

## Note

The agent equivalent of the [current realm](#) is the [surrounding agent](#).

### 8.1.2.2 Integration with the JavaScript agent cluster formalism <sup>p1073</sup>

JavaScript also defines the concept of an [agent cluster](#), which this standard maps to the web platform by placing agents appropriately when they are created using the [obtain a similar-origin window agent](#)<sup>p1073</sup> or [obtain a worker/worklet agent](#)<sup>p1074</sup> algorithms.

The [agent cluster](#) concept is crucial for defining the JavaScript memory model, and in particular among which [agents](#) the backing data of [SharedArrayBuffer](#) objects can be shared.

## Note

Conceptually, the [agent cluster](#) concept is an architecture-independent, idealized "process boundary" that groups together multiple "threads" ([agents](#)). The [agent clusters](#) defined by the specification are generally more restrictive than the actual process boundaries implemented in user agents. By enforcing these idealized divisions at the specification level, we ensure that web developers see interoperable behavior with regard to shared memory, even in the face of varying and changing user agent process models.

An [agent cluster](#) has an associated **cross-origin isolation mode**, which is a [cross-origin isolation mode](#)<sup>p1002</sup>. It is initially "[none](#)<sup>p1002</sup>".

An [agent cluster](#) has an associated **is origin-keyed** (a boolean), which is initially false.

The following defines the allocation of the [agent clusters](#) of [similar-origin window agents](#)<sup>p1072</sup>.

An **agent cluster key** is a [site](#)<sup>p899</sup> or [tuple origin](#)<sup>p898</sup>. Without web developer action to achieve [origin-keyed agent clusters](#)<sup>p902</sup>, it will be a [site](#)<sup>p899</sup>.

## Note

An equivalent formulation is that an [agent cluster key](#)<sup>p1073</sup> can be a [scheme-and-host](#)<sup>p899</sup> or an [origin](#)<sup>p898</sup>.

To **obtain a similar-origin window agent**, given an [origin](#)<sup>p898</sup> *origin*, a [browsing context group](#)<sup>p1002</sup> *group*, and a boolean *requestsOAC*, run these steps:

1. Let *site* be the result of [obtaining a site](#)<sup>p899</sup> with *origin*.
2. Let *key* be *site*.

3. If group's [cross-origin isolation mode](#)<sup>p1002</sup> is not "[none](#)<sup>p1002</sup>", then set key to *origin*.
4. Otherwise, if group's [historical agent cluster key map](#)<sup>p1002</sup>[*origin*] *exists*, then set key to group's [historical agent cluster key map](#)<sup>p1002</sup>[*origin*].
5. Otherwise:
  1. If *requestsOAC* is true, then set key to *origin*.
  2. Set group's [historical agent cluster key map](#)<sup>p1002</sup>[*origin*] to key.
6. If group's [agent cluster map](#)<sup>p1002</sup>[key] *does not exist*, then:
  1. Let *agentCluster* be a new [agent cluster](#).
  2. Set *agentCluster*'s [cross-origin isolation mode](#)<sup>p1073</sup> to group's [cross-origin isolation mode](#)<sup>p1002</sup>.
  3. Set *agentCluster*'s [is origin-keyed](#)<sup>p1073</sup> to true if key equals *origin*; otherwise false.
  4. Add the result of [creating an agent](#)<sup>p1073</sup>, given false, to *agentCluster*.
  5. Set group's [agent cluster map](#)<sup>p1002</sup>[key] to *agentCluster*.
7. Return the single [similar-origin window agent](#)<sup>p1072</sup> contained in group's [agent cluster map](#)<sup>p1002</sup>[key].

#### Note

*This means that there is only one [similar-origin window agent](#)<sup>p1072</sup> per browsing context agent cluster. (However, [dedicated worker](#)<sup>p1072</sup> and [worklet agents](#)<sup>p1072</sup> might be in the same cluster.)*

The following defines the allocation of the [agent clusters](#) of all other types of agents.

To **obtain a worker/worklet agent**, given an [environment settings object](#)<sup>p1076</sup> or null *outside settings*, a boolean *isTopLevel*, and a boolean *canBlock*, run these steps:

1. Let *agentCluster* be null.
2. If *isTopLevel* is true, then:
  1. Set *agentCluster* to a new [agent cluster](#).
  2. Set *agentCluster*'s [is origin-keyed](#)<sup>p1073</sup> to true.

#### Note

*These workers can be considered to be origin-keyed. However, this is not exposed through any APIs (in the way that [originAgentCluster](#)<sup>p903</sup> exposes the origin-keyedness for windows).*

3. Otherwise:
  1. **Assert:** *outside settings* is not null.
  2. Let *ownerAgent* be *outside settings*'s [realm](#)<sup>p1077</sup>'s [agent](#)<sup>p1073</sup>.
  3. Set *agentCluster* to the agent cluster which contains *ownerAgent*.
4. Let *agent* be the result of [creating an agent](#)<sup>p1073</sup> given *canBlock*.
5. Add *agent* to *agentCluster*.
6. Return *agent*.

To **obtain a dedicated/shared worker agent**, given an [environment settings object](#)<sup>p1076</sup> *outside settings* and a boolean *isShared*, return the result of [obtaining a worker/worklet agent](#)<sup>p1074</sup> given *outside settings*, *isShared*, and true.

To **obtain a worklet agent**, given an [environment settings object](#)<sup>p1076</sup> *outside settings*, return the result of [obtaining a worker/worklet agent](#)<sup>p1074</sup> given *outside settings*, false, and false.

To **obtain a service worker agent**, return the result of [obtaining a worker/worklet agent](#)<sup>p1074</sup> given null, true, and false.

## Example

The following pairs of global objects are each within the same [agent cluster](#), and thus can use [SharedArrayBuffer](#) instances to share memory with each other:

- A [Window](#)<sup>p922</sup> object and a dedicated worker that it created.
- A worker (of any type) and a dedicated worker it created.
- A [Window](#)<sup>p922</sup> object A and the [Window](#)<sup>p922</sup> object of an [iframe](#)<sup>p390</sup> element that A created that could be [same origin-domain](#)<sup>p899</sup> with A.
- A [Window](#)<sup>p922</sup> object and a [same origin-domain](#)<sup>p899</sup> [Window](#)<sup>p922</sup> object that opened it.
- A [Window](#)<sup>p922</sup> object and a worklet that it created.

The following pairs of global objects are *not* within the same [agent cluster](#), and thus cannot share memory:

- A [Window](#)<sup>p922</sup> object and a shared worker it created.
- A worker (of any type) and a shared worker it created.
- A [Window](#)<sup>p922</sup> object and a service worker it created.
- A [Window](#)<sup>p922</sup> object A and the [Window](#)<sup>p922</sup> object of an [iframe](#)<sup>p390</sup> element that A created that cannot be [same origin-domain](#)<sup>p899</sup> with A.
- Any two [Window](#)<sup>p922</sup> objects with no opener or ancestor relationship. This holds even if the two [Window](#)<sup>p922</sup> objects are [same origin](#)<sup>p899</sup>.

### 8.1.3 Realms and their counterparts §<sup>p10</sup><sub>75</sub>

The JavaScript specification introduces the [realm](#) concept, representing a global environment in which script is run. Each realm comes with an [implementation-defined global object](#)<sup>p1076</sup>; much of this specification is devoted to defining that global object and its properties.

For web specifications, it is often useful to associate values or algorithms with a realm/global object pair. When the values are specific to a particular type of realm, they are associated directly with the global object in question, e.g., in the definition of the [Window](#)<sup>p922</sup> or [WorkerGlobalScope](#)<sup>p1228</sup> interfaces. When the values have utility across multiple realms, we use the [environment settings object](#)<sup>p1076</sup> concept.

Finally, in some cases it is necessary to track associated values before a realm/global object/environment settings object even comes into existence (for example, during [navigation](#)<sup>p1014</sup>). These values are tracked in the [environment](#)<sup>p1075</sup> concept.

#### 8.1.3.1 Environments §<sup>p10</sup><sub>75</sub>

An **environment** is an object that identifies the settings of a current or potential execution environment (i.e., a [navigation params](#)<sup>p1013</sup>'s [reserved environment](#)<sup>p1013</sup> or a [request](#)'s [reserved client](#)). An [environment](#)<sup>p1075</sup> has the following fields:

##### An *id*

An opaque string that uniquely identifies this [environment](#)<sup>p1075</sup>.

##### A *creation URL*

A [URL](#) that represents the location of the resource with which this [environment](#)<sup>p1075</sup> is associated.

##### Note

*In the case of a [Window](#)<sup>p922</sup> [environment settings object](#)<sup>p1076</sup>, this URL might be distinct from its [global object](#)<sup>p1077</sup>'s [associated Document](#)<sup>p923</sup>'s [URL](#), due to mechanisms such as [history.pushState\(\)](#)<sup>p946</sup> which modify the latter.*

##### A *top-level creation URL*

Null or a [URL](#) that represents the [creation URL](#)<sup>p1075</sup> of the "top-level" [environment](#)<sup>p1075</sup>. It is null for workers and worklets.

### A top-level origin

A for now [implementation-defined](#) value, null, or an [origin](#)<sup>p898</sup>. For a "top-level" potential execution environment it is null (i.e., when there is no response yet); otherwise it is the "top-level" [environment](#)<sup>p1075</sup>'s [origin](#)<sup>p1076</sup>. For a dedicated worker or worklet it is the [top-level origin](#)<sup>p1076</sup> of its creator. For a shared or service worker it is an [implementation-defined](#) value.

#### Note

*This is distinct from the [top-level creation URL](#)<sup>p1075</sup>'s [origin](#) when sandboxing, workers, and worklets are involved.*

### A target browsing context

Null or a target [browsing context](#)<sup>p998</sup> for a [navigation request](#).

### An active service worker

Null or a [service worker](#) that [controls](#) the [environment](#)<sup>p1075</sup>.

### An execution ready flag

A flag that indicates whether the environment setup is done. It is initially unset.

Specifications may define **environment discarding steps** for environments. The steps take an [environment](#)<sup>p1075</sup> as input.

#### Note

*The [environment discarding steps](#)<sup>p1076</sup> are run for only a select few environments: the ones that will never become execution ready because, for example, they failed to load.*

## 8.1.3.2 Environment settings objects §<sup>p10</sup><sub>76</sub>

An **environment settings object** is an [environment](#)<sup>p1075</sup> that additionally specifies algorithms for:

### A realm execution context

A [JavaScript execution context](#) shared by all [scripts](#)<sup>p652</sup> that use this settings object, i.e., all scripts in a given [realm](#). When we [run a classic script](#)<sup>p1096</sup> or [run a module script](#)<sup>p1096</sup>, this execution context becomes the top of the [JavaScript execution context stack](#), on top of which another execution context specific to the script in question is pushed. (This setup ensures [Source Text Module Record's Evaluate](#) knows which realm to use.)

### A module map

A [module map](#)<sup>p1119</sup> that is used when importing JavaScript modules.

### An API base URL

A [URL](#) used by APIs called by scripts that use this [environment settings object](#)<sup>p1076</sup> to [parse URLs](#)<sup>p97</sup>.

### An origin

An [origin](#)<sup>p898</sup> used in security checks.

### A policy container

A [policy container](#)<sup>p917</sup> containing policies used for security checks.

### A cross-origin isolated capability

A boolean representing whether scripts that use this [environment settings object](#)<sup>p1076</sup> are allowed to use APIs that require cross-origin isolation.

### A time origin

A number used as the baseline for performance-related timestamps. [\[HRT\]](#)<sup>p1478</sup>

An [environment settings object](#)<sup>p1076</sup>'s **responsible event loop** is its [global object](#)<sup>p1077</sup>'s [relevant agent](#)<sup>p1073</sup>'s [event loop](#)<sup>p1123</sup>.

## 8.1.3.3 Realms, settings objects, and global objects §<sup>p10</sup><sub>76</sub>

A **global object** is a JavaScript object that is the `[[GlobalObject]]` field of a [realm](#).

**Note**

In this specification, all [realms](#) are [created](#)<sup>p1077</sup> with [global objects](#)<sup>p1076</sup> that are either [Window](#)<sup>p922</sup>, [WorkerGlobalScope](#)<sup>p1228</sup>, or [WorkletGlobalScope](#)<sup>p1245</sup> objects.

A [global object](#)<sup>p1076</sup> has an **in error reporting mode** boolean, which is initially false.

A [global object](#)<sup>p1076</sup> has an **outstanding rejected promises weak set**, a [set](#) of [Promise](#) objects, initially empty. This set must not create strong references to any of its members, and implementations are free to limit its size in an [implementation-defined](#) manner, e.g., by removing old entries from it when new ones are added.

A [global object](#)<sup>p1076</sup> has an **about-to-be-notified rejected promises list**, a [list](#) of [Promise](#) objects, initially empty.

A [global object](#)<sup>p1076</sup> has an **import map**, initially an [empty import map](#)<sup>p1107</sup>.

**Note**

For now, only [Window](#)<sup>p922</sup> [global objects](#)<sup>p1076</sup> have their [import map](#)<sup>p1077</sup> modified from the initial empty one. The [import map](#)<sup>p1077</sup> is only accessed for the resolution of a root [module script](#)<sup>p1085</sup>.

A [global object](#)<sup>p1076</sup> has a **resolved module set**, a [set](#) of [specifier resolution records](#)<sup>p1107</sup>, initially empty.

**Note**

The [resolved module set](#)<sup>p1077</sup> ensures that module specifier resolution returns the same result when called multiple times with the same (referrer, specifier) pair. It does that by ensuring that [import map](#)<sup>p1107</sup> rules that impact the specifier in its referrer's scope cannot be defined after its initial resolution. For now, only [Window](#)<sup>p922</sup> [global objects](#)<sup>p1076</sup> have their module set data structures modified from the initial empty one.

There is always a 1-to-1-to-1 mapping between [realms](#), [global objects](#)<sup>p1076</sup>, and [environment settings objects](#)<sup>p1076</sup>:

- A [realm](#) has a [[HostDefined]] field, which contains **the realm's settings object**.
- A [realm](#) has a [[GlobalObject]] field, which contains **the realm's global object**.
- Each [global object](#)<sup>p1076</sup> in this specification is created during the [creation](#)<sup>p1077</sup> of a corresponding [realm](#), known as **the global object's realm**.
- Each [global object](#)<sup>p1076</sup> in this specification is created alongside a corresponding [environment settings object](#)<sup>p1076</sup>, known as its [relevant settings object](#)<sup>p1083</sup>.
- An [environment settings object](#)<sup>p1076</sup>'s [realm execution context](#)<sup>p1076</sup>'s Realm component is **the environment settings object's realm**.
- An [environment settings object](#)<sup>p1076</sup>'s [realm](#)<sup>p1077</sup> then has a [[GlobalObject]] field, which contains **the environment settings object's global object**.

To **create a new realm** in an [agent](#) *agent*, optionally with instructions to create a global object or a global **this** binding (or both), the following steps are taken:

1. Perform [InitializeHostDefinedRealm\(\)](#) with the provided customizations for creating the global object and the global **this** binding.
2. Let *realm execution context* be the [running JavaScript execution context](#).

**Note**

This is the [JavaScript execution context](#) created in the previous step.

3. Remove *realm execution context* from the [JavaScript execution context stack](#).
4. Let *realm* be *realm execution context*'s Realm component.
5. If *agent*'s [agent cluster](#)'s [cross-origin isolation mode](#)<sup>p1073</sup> is "[none](#)<sup>p1002</sup>", then:
  1. Let *global* be *realm*'s [global object](#)<sup>p1077</sup>.

2. Let *status* be ! *global*.[[Delete]]("SharedArrayBuffer").
3. **Assert**: *status* is true.

#### Note

*This is done for compatibility with web content and there is some hope that this can be removed in the future. Web developers can still get at the constructor through `new WebAssembly.Memory({ shared:true, initial:0, maximum:0 }).buffer.constructor`.*

6. Return *realm* execution context.

When defining algorithm steps throughout this specification, it is often important to indicate what **realm** is to be used—or, equivalently, what **global object**<sup>p1076</sup> or **environment settings object**<sup>p1076</sup> is to be used. In general, there are at least four possibilities:

#### Entry

This corresponds to the script that initiated the currently running script action: i.e., the function or script that the user agent called into when it called into author code.

#### Incumbent

This corresponds to the most-recently-entered author function or script on the stack, or the author function or script that originally scheduled the currently-running callback.

#### Current

This corresponds to the currently-running function object, including built-in user-agent functions which might not be implemented as JavaScript. (It is derived from the **current realm**.)

#### Relevant

Every **platform object** has a **relevant realm**<sup>p1083</sup>, which is roughly the **realm** in which it was created. When writing algorithms, the most prominent **platform object** whose **relevant realm**<sup>p1083</sup> might be important is the **this** value of the currently-running function object. In some cases, there can be other important **relevant realms**<sup>p1083</sup>, such as those of any arguments.

Note how the **entry**<sup>p1078</sup>, **incumbent**<sup>p1078</sup>, and **current**<sup>p1078</sup> concepts are usable without qualification, whereas the **relevant**<sup>p1078</sup> concept must be applied to a particular **platform object**.

#### ⚠Warning!

**The **incumbent**<sup>p1078</sup> and **entry**<sup>p1078</sup> concepts should not be used by new specifications, as they are excessively complicated and unintuitive to work with. We are working to remove almost all existing uses from the platform: see [issue #1430](#) for **incumbent**<sup>p1078</sup>, and [issue #1431](#) for **entry**<sup>p1078</sup>.**

In general, web platform specifications should use the **relevant**<sup>p1078</sup> concept, applied to the object being operated on (usually the **this** value of the current method). This mismatches the JavaScript specification, where **current**<sup>p1078</sup> is generally used as the default (e.g., in determining the **realm** whose **Array** constructor should be used to construct the result in `Array.prototype.map`). But this inconsistency is so embedded in the platform that we have to accept it going forward.

#### Example

Consider the following pages, with `a.html` being loaded in a browser window, `b.html` being loaded in an **iframe**<sup>p399</sup> as shown, and `c.html` and `d.html` omitted (they can simply be empty documents):

```
<!-- a.html -->
<!DOCTYPE html>
<html lang="en">
<title>Entry page</title>

<iframe src="b.html"></iframe>
<button onclick="frames[0].hello()">Hello</button>

<!-- b.html -->
<!DOCTYPE html>
<html lang="en">
<title>Incumbent page</title>
```

```

<iframe src="c.html" id="c"></iframe>
<iframe src="d.html" id="d"></iframe>

<script>
  const c = document.querySelector("#c").contentWindow;
  const d = document.querySelector("#d").contentWindow;

  window.hello = () => {
    c.print.call(d);
  };
</script>

```

Each page has its own [browsing context](#)<sup>p998</sup>, and thus its own [realm](#), [global object](#)<sup>p1076</sup>, and [environment settings object](#)<sup>p1076</sup>.

When the [print\(\)](#)<sup>p1169</sup> method is called in response to pressing the button in a.html, then:

- The [entry realm](#)<sup>p1080</sup> is that of a.html.
- The [incumbent realm](#)<sup>p1081</sup> is that of b.html.
- The [current realm](#) is that of c.html (since it is the [print\(\)](#)<sup>p1169</sup> method from c.html whose code is running).
- The [relevant realm](#)<sup>p1083</sup> of the object on which the [print\(\)](#)<sup>p1169</sup> method is being called is that of d.html.

#### Example

One reason why the [relevant](#)<sup>p1078</sup> concept is generally a better default choice than the [current](#)<sup>p1078</sup> concept is that it is more suitable for creating an object that is to be persisted and returned multiple times. For example, the [navigator.getBattery\(\)](#) method creates promises in the [relevant realm](#)<sup>p1083</sup> for the [Navigator](#)<sup>p1170</sup> object on which it is invoked. This has the following impact: [\[BATTERY\]](#)<sup>p1475</sup>

```

<!-- outer.html -->
<!DOCTYPE html>
<html lang="en">
<title>Relevant realm demo: outer page</title>
<script>
  function doTest() {
    const promise = navigator.getBattery.call(frames[0].navigator);

    console.log(promise instanceof Promise); // logs false
    console.log(promise instanceof frames[0].Promise); // logs true

    frames[0].hello();
  }
</script>
<iframe src="inner.html" onload="doTest()"></iframe>

<!-- inner.html -->
<!DOCTYPE html>
<html lang="en">
<title>Relevant realm demo: inner page</title>
<script>
  function hello() {
    const promise = navigator.getBattery();

    console.log(promise instanceof Promise); // logs true
    console.log(promise instanceof parent.Promise); // logs false
  }
</script>

```

If the algorithm for the `getBattery()` method had instead used the [current realm](#), all the results would be reversed. That is, after the first call to `getBattery()` in `outer.html`, the `Navigator`<sup>p1179</sup> object in `inner.html` would be permanently storing a Promise object created in `outer.html`'s [realm](#), and calls like that inside the `hello()` function would thus return a promise from the "wrong" realm. Since this is undesirable, the algorithm instead uses the [relevant realm](#)<sup>p1083</sup>, giving the sensible results indicated in the comments above.

The rest of this section deals with formally defining the [entry](#)<sup>p1078</sup>, [incumbent](#)<sup>p1078</sup>, [current](#)<sup>p1078</sup>, and [relevant](#)<sup>p1078</sup> concepts.

#### 8.1.3.3.1 Entry <sup>p1080</sup>

The process of [calling scripts](#)<sup>p1096</sup> will push or pop [realm execution contexts](#)<sup>p1076</sup> onto the [JavaScript execution context stack](#), interspersed with other [execution contexts](#).

With this in hand, we define the **entry execution context** to be the most recently pushed item in the [JavaScript execution context stack](#) that is a [realm execution context](#)<sup>p1076</sup>. The **entry realm** is the [entry execution context](#)<sup>p1080</sup>'s Realm component.

Then, the **entry settings object** is the [environment settings object](#)<sup>p1077</sup> of the [entry realm](#)<sup>p1080</sup>.

Similarly, the **entry global object** is the [global object](#)<sup>p1077</sup> of the [entry realm](#)<sup>p1080</sup>.

#### 8.1.3.3.2 Incumbent <sup>p1080</sup>

All [JavaScript execution contexts](#) must contain, as part of their code evaluation state, a **skip-when-determining-incumbent counter** value, which is initially zero. In the process of [preparing to run a callback](#)<sup>p1080</sup> and [cleaning up after running a callback](#)<sup>p1080</sup>, this value will be incremented and decremented.

Every [event loop](#)<sup>p1123</sup> has an associated **backup incumbent settings object stack**, initially empty. Roughly speaking, it is used to determine the [incumbent settings object](#)<sup>p1081</sup> when no author code is on the stack, but author code is responsible for the current algorithm having been run in some way. The process of [preparing to run a callback](#)<sup>p1080</sup> and [cleaning up after running a callback](#)<sup>p1080</sup> manipulate this stack. [WEBIDL]<sup>p1483</sup>

When Web IDL is used to [invoke](#) author code, or when [HostEnqueuePromiseJob](#)<sup>p1117</sup> invokes a promise job, they use the following algorithms to track relevant data for determining the [incumbent settings object](#)<sup>p1081</sup>:

To **prepare to run a callback** with an [environment settings object](#)<sup>p1076</sup> *settings*:

1. Push *settings* onto the [backup incumbent settings object stack](#)<sup>p1080</sup>.
2. Let *context* be the [topmost script-having execution context](#)<sup>p1080</sup>.
3. If *context* is not null, increment *context*'s [skip-when-determining-incumbent counter](#)<sup>p1080</sup>.

To **clean up after running a callback** with an [environment settings object](#)<sup>p1076</sup> *settings*:

1. Let *context* be the [topmost script-having execution context](#)<sup>p1080</sup>.

#### Note

*This will be the same as the [topmost script-having execution context](#)<sup>p1080</sup> inside the corresponding invocation of [prepare to run a callback](#)<sup>p1080</sup>.*

2. If *context* is not null, decrement *context*'s [skip-when-determining-incumbent counter](#)<sup>p1080</sup>.
3. **Assert**: the topmost entry of the [backup incumbent settings object stack](#)<sup>p1080</sup> is *settings*.
4. Remove *settings* from the [backup incumbent settings object stack](#)<sup>p1080</sup>.

Here, the **topmost script-having execution context** is the topmost entry of the [JavaScript execution context stack](#) that has a non-null ScriptOrModule component, or null if there is no such entry in the [JavaScript execution context stack](#).

With all this in place, the **incumbent settings object** is determined as follows:

1. Let *context* be the [topmost script-having execution context](#)<sup>p1080</sup>.
2. If *context* is null, or if *context*'s [skip-when-determining-incumbent counter](#)<sup>p1080</sup> is greater than zero, then:
  1. **Assert:** the [backup incumbent settings object stack](#)<sup>p1080</sup> is not empty.

**Note**

*This assert would fail if you try to obtain the [incumbent settings object](#)<sup>p1081</sup> from inside an algorithm that was triggered neither by [calling scripts](#)<sup>p1096</sup> nor by Web IDL [invoking](#) a callback. For example, it would trigger if you tried to obtain the [incumbent settings object](#)<sup>p1081</sup> inside an algorithm that ran periodically as part of the [event loop](#)<sup>p1123</sup>, with no involvement of author code. In such cases the [incumbent](#)<sup>p1078</sup> concept cannot be used.*

2. Return the topmost entry of the [backup incumbent settings object stack](#)<sup>p1080</sup>.
3. Return *context*'s Realm component's [settings object](#)<sup>p1077</sup>.

Then, the **incumbent realm** is the [realm](#)<sup>p1077</sup> of the [incumbent settings object](#)<sup>p1081</sup>.

Similarly, the **incumbent global object** is the [global object](#)<sup>p1077</sup> of the [incumbent settings object](#)<sup>p1081</sup>.

The following series of examples is intended to make it clear how all of the different mechanisms contribute to the definition of the [incumbent](#)<sup>p1080</sup> concept:

**Example**

Consider the following starter example:

```
<!DOCTYPE html>
<iframe></iframe>
<script>
  frames[0].postMessage("some data", "*");
</script>
```

There are two interesting [environment settings objects](#)<sup>p1076</sup> here: that of window, and that of frames[0]. Our concern is: what is the [incumbent settings object](#)<sup>p1081</sup> at the time that the algorithm for [postMessage\(\)](#)<sup>p1201</sup> executes?

It should be that of window, to capture the intuitive notion that the author script responsible for causing the algorithm to happen is executing in window, not frames[0]. This makes sense: the [window post message steps](#)<sup>p1201</sup> use the [incumbent settings object](#)<sup>p1081</sup> to determine the [source](#)<sup>p1190</sup> property of the resulting [MessageEvent](#)<sup>p1189</sup>, and in this case window is definitely the source of the message.

Let us now explain how the steps given above give us our intuitively-desired result of window's [relevant settings object](#)<sup>p1083</sup>.

When the [window post message steps](#)<sup>p1201</sup> look up the [incumbent settings object](#)<sup>p1081</sup>, the [topmost script-having execution context](#)<sup>p1080</sup> will be that corresponding to the [script](#)<sup>p652</sup> element: it was pushed onto the [JavaScript execution context stack](#) as part of [ScriptEvaluation](#) during the [run a classic script](#)<sup>p1096</sup> algorithm. Since there are no Web IDL callback invocations involved, the context's [skip-when-determining-incumbent counter](#)<sup>p1080</sup> is zero, so it is used to determine the [incumbent settings object](#)<sup>p1081</sup>; the result is the [environment settings object](#)<sup>p1076</sup> of window.

(Note how the [environment settings object](#)<sup>p1076</sup> of frames[0] is the [relevant settings object](#)<sup>p1083</sup> of [this](#) at the time the [postMessage\(\)](#)<sup>p1201</sup> method is called, and thus is involved in determining the *target* of the message. Whereas the incumbent is used to determine the *source*.)

**Example**

Consider the following more complicated example:

```
<!DOCTYPE html>
<iframe></iframe>
<script>
```

```
const bound = frames[0].postMessage.bind(frames[0], "some data", "*");
window.setTimeout(bound);
</script>
```

This example is very similar to the previous one, but with an extra indirection through `Function.prototype.bind` as well as [setTimeout\(\)](#)<sup>p1162</sup>. But, the answer should be the same: invoking algorithms asynchronously should not change the [incumbent](#)<sup>p1078</sup> concept.

This time, the result involves more complicated mechanisms:

When `bound` is [converted](#) to a Web IDL callback type, the [incumbent settings object](#)<sup>p1081</sup> is that corresponding to `window` (in the same manner as in our starter example above). Web IDL stores this as the resulting callback value's [callback context](#).

When the [task](#)<sup>p1124</sup> posted by [setTimeout\(\)](#)<sup>p1162</sup> executes, the algorithm for that task uses Web IDL to [invoke](#) the stored callback value. Web IDL in turn calls the above [prepare to run a callback](#)<sup>p1080</sup> algorithm. This pushes the stored [callback context](#) onto the [backup incumbent settings object stack](#)<sup>p1080</sup>. At this time (inside the timer task) there is no author code on the stack, so the [topmost script-having execution context](#)<sup>p1080</sup> is null, and nothing gets its [skip-when-determining-incumbent-counter](#)<sup>p1080</sup> incremented.

Invoking the callback then calls `bound`, which in turn calls the [postMessage\(\)](#)<sup>p1201</sup> method of `frames[0]`. When the [postMessage\(\)](#)<sup>p1201</sup> algorithm looks up the [incumbent settings object](#)<sup>p1081</sup>, there is still no author code on the stack, since the `bound` function just directly calls the built-in method. So the [topmost script-having execution context](#)<sup>p1080</sup> will be null: the [JavaScript execution context](#) stack only contains an execution context corresponding to [postMessage\(\)](#)<sup>p1201</sup>, with no [ScriptEvaluation](#) context or similar below it.

This is where we fall back to the [backup incumbent settings object stack](#)<sup>p1080</sup>. As noted above, it will contain as its topmost entry the [relevant settings object](#)<sup>p1083</sup> of `window`. So that is what is used as the [incumbent settings object](#)<sup>p1081</sup> while executing the [postMessage\(\)](#)<sup>p1201</sup> algorithm.

## Example

Consider this final, even more convoluted example:

```
<!-- a.html -->
<!DOCTYPE html>
<button>click me</button>
<iframe></iframe>
<script>
const bound = frames[0].location.assign.bind(frames[0].location, "https://example.com/");
document.querySelector("button").addEventListener("click", bound);
</script>
```

```
<!-- b.html -->
<!DOCTYPE html>
<iframe src="a.html"></iframe>
<script>
const iframe = document.querySelector("iframe");
iframe.onload = function onLoad() {
  iframe.contentWindow.document.querySelector("button").click();
};
</script>
```

Again there are two interesting [environment settings objects](#)<sup>p1076</sup> in play: that of `a.html`, and that of `b.html`. When the [location.assign\(\)](#)<sup>p942</sup> method triggers the [Location-object navigate](#)<sup>p939</sup> algorithm, what will be the [incumbent settings object](#)<sup>p1081</sup>? As before, it should intuitively be that of `a.html`: the [click](#) listener was originally scheduled by `a.html`, so even if something involving `b.html` causes the listener to fire, the [incumbent](#)<sup>p1078</sup> responsible is that of `a.html`.

The callback setup is similar to the previous example: when `bound` is [converted](#) to a Web IDL callback type, the [incumbent settings object](#)<sup>p1081</sup> is that corresponding to `a.html`, which is stored as the callback's [callback context](#).

When the [click\(\)](#)<sup>p833</sup> method is called inside `b.html`, it [dispatches](#) a [click](#) event on the button that is inside `a.html`. This time, when the [prepare to run a callback](#)<sup>p1080</sup> algorithm executes as part of event dispatch, there *is* author code on the stack; the [topmost script-having execution context](#)<sup>p1080</sup> is that of the `onLoad` function, whose [skip-when-determining-incumbent counter](#)<sup>p1080</sup> gets incremented. Additionally, `a.html`'s [environment settings object](#)<sup>p1076</sup> (stored as the [EventHandler](#)<sup>p1141</sup>'s [callback context](#)) is pushed onto the [backup incumbent settings object stack](#)<sup>p1080</sup>.

Now, when the [Location-object navigate](#)<sup>p939</sup> algorithm looks up the [incumbent settings object](#)<sup>p1081</sup>, the [topmost script-having execution context](#)<sup>p1080</sup> is still that of the `onLoad` function (due to the fact we are using a bound function as the callback). Its [skip-when-determining-incumbent counter](#)<sup>p1080</sup> value is one, however, so we fall back to the [backup incumbent settings object stack](#)<sup>p1080</sup>. This gives us the [environment settings object](#)<sup>p1076</sup> of `a.html`, as expected.

Note that this means that even though it is the [iframe](#)<sup>p398</sup> inside `a.html` that navigates, it is `a.html` itself that is used as the source [Document](#)<sup>p138</sup>, which determines among other things the [request client](#). This is [perhaps the only justifiable use of the incumbent concept on the web platform](#); in all other cases the consequences of using it are simply confusing and we hope to one day switch them to use [current](#)<sup>p1078</sup> or [relevant](#)<sup>p1078</sup> as appropriate.

#### 8.1.3.3.3 Current <sup>§<sup>p10</sup><sub>83</sub></sup>

The JavaScript specification defines the [current realm](#), also known as the "current Realm Record". [\[JAVASCRIPT\]](#)<sup>p1479</sup>

Then, the **current settings object** is the [environment settings object](#)<sup>p1077</sup> of the [current realm](#).

Similarly, the **current global object** is the [global object](#)<sup>p1077</sup> of the [current realm](#).

#### 8.1.3.3.4 Relevant <sup>§<sup>p10</sup><sub>83</sub></sup>

The **relevant realm** for a [platform object](#) is the value of its `[[Realm]]` field.

Then, the **relevant settings object** for a [platform object](#) `o` is the [environment settings object](#)<sup>p1077</sup> of the [relevant realm](#)<sup>p1083</sup> for `o`.

Similarly, the **relevant global object** for a [platform object](#) `o` is the [global object](#)<sup>p1077</sup> of the [relevant realm](#)<sup>p1083</sup> for `o`.

#### 8.1.3.4 Enabling and disabling scripting <sup>§<sup>p10</sup><sub>83</sub></sup>

**Scripting is enabled** for an [environment settings object](#)<sup>p1076</sup> *settings* when all of the following conditions are true:

- The user agent supports scripting.
- The user has not disabled scripting for *settings* at this time. (User agents may provide users with the option to disable scripting globally, or in a finer-grained manner, e.g., on a per-origin basis, down to the level of individual [environment settings objects](#)<sup>p1076</sup>.)
- Either *settings*'s [global object](#)<sup>p1077</sup> is not a [Window](#)<sup>p922</sup> object, or *settings*'s [global object](#)<sup>p1077</sup>'s [associated Document](#)<sup>p923</sup>'s [active sandboxing flag set](#)<sup>p917</sup> does not have its [sandboxed scripts browsing context flag](#)<sup>p915</sup> set.

**Scripting is disabled** for an [environment settings object](#)<sup>p1076</sup> when scripting is not [enabled](#)<sup>p1083</sup> for it, i.e., when any of the above conditions are false.

**Scripting is enabled** for a node *node* if *node*'s [node document](#)'s [browsing context](#)<sup>p999</sup> is non-null, and [scripting is enabled](#)<sup>p1083</sup> for *node*'s [relevant settings object](#)<sup>p1083</sup>.

**Scripting is disabled** for a node when scripting is not [enabled](#)<sup>p1083</sup>, i.e., when its [node document](#)'s [browsing context](#)<sup>p999</sup> is null or when [scripting is disabled](#)<sup>p1083</sup> for its [relevant settings object](#)<sup>p1083</sup>.

### 8.1.3.5 Secure contexts § p1084

An [environment](#)<sup>p1075</sup> *environment* is a **secure context** if the following algorithm returns true:

1. If *environment* is an [environment settings object](#)<sup>p1076</sup>, then:
  1. Let *global* be *environment*'s [global object](#)<sup>p1077</sup>.
  2. If *global* is a [WorkerGlobalScope](#)<sup>p1228</sup>, then:
    1. If *global*'s [owner set](#)<sup>p1228</sup>[0]'s [relevant settings object](#)<sup>p1083</sup> is a [secure context](#)<sup>p1084</sup>, then return true.

#### Note

*We only need to check the 0th item since they will necessarily all be consistent.*

2. Return false.
3. If *global* is a [WorkletGlobalScope](#)<sup>p1245</sup>, then return true.

#### Note

*Worklets can only be created in secure contexts.*

2. If the result of [Is url potentially trustworthy?](#) given *environment*'s [top-level creation URL](#)<sup>p1075</sup> is "Potentially Trustworthy", then return true.
3. Return false.

An [environment](#)<sup>p1075</sup> is a **non-secure context** if it is not a [secure context](#)<sup>p1084</sup>.

### 8.1.4 Script processing model § p1084

#### 8.1.4.1 Scripts § p1084

A **script** is one of two possible [structs](#) (namely, a [classic script](#)<sup>p1085</sup> or a [module script](#)<sup>p1085</sup>). All scripts have:

##### A settings object

An [environment settings object](#)<sup>p1076</sup>, containing various settings that are shared with other [scripts](#)<sup>p1084</sup> in the same context.

##### A record

One of the following:

- a [script record](#), for [classic scripts](#)<sup>p1085</sup>;
- a [Source Text Module Record](#), for [JavaScript module scripts](#)<sup>p1085</sup>;
- a [Synthetic Module Record](#), for [CSS module scripts](#)<sup>p1085</sup> and [JSON module scripts](#)<sup>p1085</sup>;
- a [WebAssembly Module Record](#), for [WebAssembly module scripts](#)<sup>p1085</sup>; or
- null, representing a parsing failure.

##### A parse error

A JavaScript value, which has meaning only if the [record](#)<sup>p1084</sup> is null, indicating that the corresponding script source text could not be parsed.

#### Note

*This value is used for internal tracking of immediate parse errors when [creating scripts](#)<sup>p1093</sup>, and is not to be used directly. Instead, consult the [error to rethrow](#)<sup>p1084</sup> when determining "what went wrong" for this script.*

##### An error to rethrow

A JavaScript value representing an error that will prevent evaluation from succeeding. It will be re-thrown by any attempts to [run](#)<sup>p1096</sup> the script.

#### Note

This could be the script's [parse error](#)<sup>p1084</sup>, but in the case of a [module script](#)<sup>p1085</sup> it could instead be the [parse error](#)<sup>p1084</sup> from one of its dependencies, or an error from [resolve a module specifier](#)<sup>p1102</sup>.

#### Note

Since this exception value is provided by the JavaScript specification, we know that it is never null, so we use null to signal that no error has occurred.

### Fetch options

Null or a [script fetch options](#)<sup>p1085</sup>, containing various options related to fetching this script or [module scripts](#)<sup>p1085</sup> that it imports.

### A base URL

Null or a base [URL](#) used for [resolving module specifiers](#)<sup>p1102</sup>. When non-null, this will either be the URL from which the script was obtained, for external scripts, or the [document base URL](#)<sup>p96</sup> of the containing document, for inline scripts.

A **classic script** is a type of [script](#)<sup>p1084</sup> that has the following additional [item](#):

### A muted errors boolean

A boolean which, if true, means that error information will not be provided for errors in this script. This is used to mute errors for cross-origin scripts, since that can leak private information.

A **module script** is another type of [script](#)<sup>p1084</sup>. It has no additional [items](#).

[Module scripts](#)<sup>p1085</sup> can be classified into four types:

- A [module script](#)<sup>p1085</sup> is a **JavaScript module script** if its [record](#)<sup>p1084</sup> is a [Source Text Module Record](#).
- A [module script](#)<sup>p1085</sup> is a **CSS module script** if its [record](#)<sup>p1084</sup> is a [Synthetic Module Record](#), and it was created via the [create a CSS module script](#)<sup>p1094</sup> algorithm. CSS module scripts represent a parsed CSS stylesheet.
- A [module script](#)<sup>p1085</sup> is a **JSON module script** if its [record](#)<sup>p1084</sup> is a [Synthetic Module Record](#), and it was created via the [create a JSON module script](#)<sup>p1095</sup> algorithm. JSON module scripts represent a parsed JSON document.
- A [module script](#)<sup>p1085</sup> is a **WebAssembly module script** if its [record](#)<sup>p1084</sup> is a [WebAssembly Module Record](#).

#### Note

As CSS stylesheets and JSON documents do not import dependent modules, and do not throw exceptions on evaluation, the [fetch options](#)<sup>p1085</sup> and [base URL](#)<sup>p1085</sup> of [CSS module scripts](#)<sup>p1085</sup> and [JSON module scripts](#)<sup>p1085</sup> are always null.

The **active script** is determined by the following algorithm:

1. Let *record* be [GetActiveScriptOrModule](#)() .
2. If *record* is null, return null.
3. Return *record*.[\[\[HostDefined\]\]](#).

#### Note

The [active script](#)<sup>p1085</sup> concept is so far only used by the [import\(\)](#) feature, to determine the [base URL](#)<sup>p1085</sup> to use for resolving relative module specifiers.

### 8.1.4.2 Fetching scripts <sup>p1085</sup>

This section introduces a number of algorithms for fetching scripts, taking various necessary inputs and resulting in [classic](#)<sup>p1085</sup> or [module scripts](#)<sup>p1085</sup>.

**Script fetch options** is a [struct](#) with the following [items](#):

### **cryptographic nonce**

The [cryptographic nonce metadata](#) used for the initial fetch and for fetching any imported modules

### **integrity metadata**

The [integrity metadata](#) used for the initial fetch

### **parser metadata**

The [parser metadata](#) used for the initial fetch and for fetching any imported modules

### **credentials mode**

The [credentials mode](#) used for the initial fetch (for [module scripts](#)<sup>p1085</sup>) and for fetching any imported modules (for both [module scripts](#)<sup>p1085</sup> and [classic scripts](#)<sup>p1085</sup>)

### **referrer policy**

The [referrer policy](#) used for the initial fetch and for fetching any imported modules

#### **Note**

*This policy can mutate after a [module script](#)<sup>p1085</sup>'s [response](#) is received, to be the [referrer policy parsed](#) from the [response](#), and used when fetching any module dependencies.*

### **render-blocking**

The boolean value of [render-blocking](#) used for the initial fetch and for fetching any imported modules. Unless otherwise stated, its value is false.

### **fetch priority**

The [priority](#) used for the initial fetch

#### **Note**

*Recall that via the [import\(\)](#) feature, [classic scripts](#)<sup>p1085</sup> can import [module scripts](#)<sup>p1085</sup>.*

The **default script fetch options** are a [script fetch options](#)<sup>p1085</sup> whose [cryptographic nonce](#)<sup>p1086</sup> is the empty string, [integrity metadata](#)<sup>p1086</sup> is the empty string, [parser metadata](#)<sup>p1086</sup> is "not-parser-inserted", [credentials mode](#)<sup>p1086</sup> is "same-origin", [referrer policy](#)<sup>p1086</sup> is the empty string, and [fetch priority](#)<sup>p1086</sup> is "auto".

Given a [request](#) *request* and a [script fetch options](#)<sup>p1085</sup> *options*, we define:

#### **set up the classic script request**

Set *request*'s [cryptographic nonce metadata](#) to *options*'s [cryptographic nonce](#)<sup>p1086</sup>, its [integrity metadata](#) to *options*'s [integrity metadata](#)<sup>p1086</sup>, its [parser metadata](#) to *options*'s [parser metadata](#)<sup>p1086</sup>, its [referrer policy](#) to *options*'s [referrer policy](#)<sup>p1086</sup>, its [render-blocking](#) to *options*'s [render-blocking](#)<sup>p1086</sup>, and its [priority](#) to *options*'s [fetch priority](#)<sup>p1086</sup>.

#### **set up the module script request**

Set *request*'s [cryptographic nonce metadata](#) to *options*'s [cryptographic nonce](#)<sup>p1086</sup>, its [integrity metadata](#) to *options*'s [integrity metadata](#)<sup>p1086</sup>, its [parser metadata](#) to *options*'s [parser metadata](#)<sup>p1086</sup>, its [credentials mode](#) to *options*'s [credentials mode](#)<sup>p1086</sup>, its [referrer policy](#) to *options*'s [referrer policy](#)<sup>p1086</sup>, its [render-blocking](#) to *options*'s [render-blocking](#)<sup>p1086</sup>, and its [priority](#) to *options*'s [fetch priority](#)<sup>p1086</sup>.

To **get the descendant script fetch options** given a [script fetch options](#)<sup>p1085</sup> *originalOptions*, a [URL](#) *url*, and an [environment settings object](#)<sup>p1076</sup> *settingsObject*:

1. Let *newOptions* be a copy of *originalOptions*.
2. Let *integrity* be the result of [resolving a module integrity metadata](#)<sup>p1086</sup> with *url* and *settingsObject*.
3. Set *newOptions*'s [integrity metadata](#)<sup>p1086</sup> to *integrity*.
4. Set *newOptions*'s [fetch priority](#)<sup>p1086</sup> to "auto".
5. Return *newOptions*.

To **resolve a module integrity metadata**, given a [URL](#) *url* and an [environment settings object](#)<sup>p1076</sup> *settingsObject*:

1. Let *map* be *settingsObject*'s [global object](#)<sup>p1077</sup>'s [import map](#)<sup>p1077</sup>.
2. If *map*'s [integrity](#)<sup>p1107</sup>[*url*] does not [exist](#), then return the empty string.
3. Return *map*'s [integrity](#)<sup>p1107</sup>[*url*].

Several of the below algorithms can be customized with a **perform the fetch hook** algorithm, which takes a [request](#), a boolean [isTopLevel](#)<sup>p1087</sup>, and a **processCustomFetchResponse** algorithm. It runs [processCustomFetchResponse](#)<sup>p1087</sup> with a [response](#) and either null (on failure) or a [byte sequence](#) containing the response body. **isTopLevel** will be true for all [classic script](#)<sup>p1085</sup> fetches, and for the initial fetch when [fetching an external module script graph](#)<sup>p1089</sup> or [fetching a module worker script graph](#)<sup>p1090</sup>, but false for the fetches resulting from `import` statements encountered throughout the graph or from `import()` expressions.

By default, not supplying a [perform the fetch hook](#)<sup>p1087</sup> will cause the below algorithms to simply [fetch](#) the given [request](#), with algorithm-specific customizations to the [request](#) and validations of the resulting [response](#).

To layer your own customizations on top of these algorithm-specific ones, supply a [perform the fetch hook](#)<sup>p1087</sup> that modifies the given [request](#), [fetches](#) it, and then performs specific validations of the resulting [response](#) (completing with a [network error](#) if the validations fail).

The hook can also be used to perform more subtle customizations, such as keeping a cache of [responses](#) and avoiding performing a [fetch](#) at all.

#### Note

*Service Workers is an example of a specification that runs these algorithms with its own options for the hook. [\[SW\]](#)<sup>p1482</sup>*

Now for the algorithms themselves.

To **fetch a classic script** given a [URL](#) *url*, an [environment settings object](#)<sup>p1076</sup> *settingsObject*, a [script fetch options](#)<sup>p1085</sup> *options*, a [CORS settings attribute state](#)<sup>p99</sup> *corsSetting*, an [encoding](#) *encoding*, and an algorithm *onComplete*, run these steps. *onComplete* must be an algorithm accepting null (on failure) or a [classic script](#)<sup>p1085</sup> (on success).

1. Let *request* be the result of [creating a potential-CORS request](#)<sup>p98</sup> given *url*, "script", and *corsSetting*.
2. Set *request*'s [client](#) to *settingsObject*.
3. Set *request*'s [initiator type](#) to "script".
4. [Set up the classic script request](#)<sup>p1086</sup> given *request* and *options*.
5. [Fetch](#) *request* with the following [processResponseConsumeBody](#) steps given [response](#) *response* and null, failure, or a [byte sequence](#) *bodyBytes*:

#### Note

*response can be either [CORS-same-origin](#)<sup>p98</sup> or [CORS-cross-origin](#)<sup>p98</sup>. This only affects how error reporting happens.*

1. Set *response* to *response*'s [unsafe response](#)<sup>p98</sup>.
2. If any of the following are true:
  - *bodyBytes* is null or failure; or
  - *response*'s [status](#) is not an [ok status](#),

then run *onComplete* given null, and abort these steps.

#### Note

*For historical reasons, this algorithm does not include MIME type checking, unlike the other script-fetching algorithms in this section.*

3. Let *potentialMIMETypeForEncoding* be the result of [extracting a MIME type](#) given *response*'s [header list](#).
4. Set *encoding* to the result of [legacy extracting an encoding](#) given *potentialMIMETypeForEncoding* and *encoding*.

**Note**

*This intentionally ignores the [MIME type essence](#).*

- Let *sourceText* be the result of [decoding](#) *bodyBytes* to Unicode, using *encoding* as the fallback encoding.

**Note**

*The [decode](#) algorithm overrides encoding if the file contains a BOM.*

- Let *mutedErrors* be true if *response* was [CORS-cross-origin](#)<sup>p98</sup>, and false otherwise.
- Let *script* be the result of [creating a classic script](#)<sup>p1093</sup> given *sourceText*, *settingsObject*, *response*'s [URL](#), *options*, *mutedErrors*, and *url*.
- Run *onComplete* given *script*.

To **fetch a classic worker script** given a [URL](#) *url*, an [environment settings object](#)<sup>p1076</sup> *fetchClient*, a [destination](#) *destination*, an [environment settings object](#)<sup>p1076</sup> *settingsObject*, an algorithm *onComplete*, and an optional [perform the fetch hook](#)<sup>p1087</sup> *performFetch*, run these steps. *onComplete* must be an algorithm accepting null (on failure) or a [classic script](#)<sup>p1085</sup> (on success).

- Let *request* be a new [request](#) whose [URL](#) is *url*, [client](#) is *fetchClient*, [destination](#) is *destination*, [initiator type](#) is "other", [mode](#) is "same-origin", [credentials mode](#) is "same-origin", [parser metadata](#) is "not parser-inserted", and whose [use-URL-credentials flag](#) is set.
- If *performFetch* was given, run *performFetch* with *request*, true, and with *processResponseConsumeBody* as defined below.

Otherwise, [fetch](#) *request* with [processResponseConsumeBody](#) set to *processResponseConsumeBody* as defined below.

In both cases, let *processResponseConsumeBody* given [response](#) *response* and null, failure, or a [byte sequence](#) *bodyBytes* be the following algorithm:

- Set *response* to *response*'s [unsafe response](#)<sup>p98</sup>.
- If any of the following are true:
  - bodyBytes* is null or failure; or
  - response*'s [status](#) is not an [ok status](#),
 then run *onComplete* given null, and abort these steps.
- If all of the following are true:
  - response*'s [URL](#)'s [scheme](#) is an [HTTP\(S\) scheme](#); and
  - the result of [extracting a MIME type](#) from *response*'s [header list](#) is not a [JavaScript MIME type](#),
 then run *onComplete* given null, and abort these steps.

**Note**

*Other [fetch schemes](#) are exempted from MIME type checking for historical web-compatibility reasons. We might be able to tighten this in the future; see [issue #3255](#).*

- Let *sourceText* be the result of [UTF-8 decoding](#) *bodyBytes*.
- Let *script* be the result of [creating a classic script](#)<sup>p1093</sup> using *sourceText*, *settingsObject*, *response*'s [URL](#), and the [default script fetch options](#)<sup>p1086</sup>.
- Run *onComplete* given *script*.

To **fetch a classic worker-imported script** given a [URL](#) *url*, an [environment settings object](#)<sup>p1076</sup> *settingsObject*, and an optional [perform the fetch hook](#)<sup>p1087</sup> *performFetch*, run these steps. The algorithm will return a [classic script](#)<sup>p1085</sup> on success, or throw an exception on failure.

- Let *response* be null.
- Let *bodyBytes* be null.
- Let *request* be a new [request](#) whose [URL](#) is *url*, [client](#) is *settingsObject*, [destination](#) is "script", [initiator type](#) is "other", [parser metadata](#) is "not parser-inserted", and whose [use-URL-credentials flag](#) is set.

4. If `performFetch` was given, run `performFetch` with `request`, `isTopLevel`, and with `processResponseConsumeBody` as defined below.

Otherwise, `fetch` request with `processResponseConsumeBody` set to `processResponseConsumeBody` as defined below.

In both cases, let `processResponseConsumeBody` given `response` `res` and null, failure, or a `byte sequence` `bb` be the following algorithm:

1. Set `bodyBytes` to `bb`.
  2. Set `response` to `res`.
5. `Pause`<sup>p1133</sup> until `response` is not null.

#### Note

*Unlike other algorithms in this section, the fetching process is synchronous here.*

6. Set `response` to `response`'s `unsafe response`<sup>p98</sup>.
7. If any of the following are true:
  - `bodyBytes` is null or failure;
  - `response`'s `status` is not an `ok status`; or
  - the result of `extracting a MIME type` from `response`'s `header list` is not a `JavaScript MIME type`,then throw a `"NetworkError" DOMException`.
8. Let `sourceText` be the result of `UTF-8 decoding` `bodyBytes`.
9. Let `mutedErrors` be true if `response` was `CORS-cross-origin`<sup>p98</sup>, and false otherwise.
10. Let `script` be the result of `creating a classic script`<sup>p1093</sup> given `sourceText`, `settingsObject`, `response`'s `URL`, the `default script fetch options`<sup>p1086</sup>, and `mutedErrors`.
11. Return `script`.

To **fetch an external module script graph** given a `URL` `url`, an `environment settings object`<sup>p1076</sup> `settingsObject`, a `script fetch options`<sup>p1085</sup> `options`, and an algorithm `onComplete`, run these steps. `onComplete` must be an algorithm accepting null (on failure) or a `module script`<sup>p1085</sup> (on success).

1. `Fetch a single module script`<sup>p1091</sup> given `url`, `settingsObject`, `"script"`, `options`, `settingsObject`, `"client"`, true, and with the following steps given `result`:
  1. If `result` is null, run `onComplete` given null, and abort these steps.
  2. `Fetch the descendants of and link`<sup>p1091</sup> `result` given `settingsObject`, `"script"`, and `onComplete`.

To **fetch a modulepreload module script graph** given a `URL` `url`, a `destination` `destination`, an `environment settings object`<sup>p1076</sup> `settingsObject`, a `script fetch options`<sup>p1085</sup> `options`, and an algorithm `onComplete`, run these steps. `onComplete` must be an algorithm accepting null (on failure) or a `module script`<sup>p1085</sup> (on success).

1. `Fetch a single module script`<sup>p1091</sup> given `url`, `settingsObject`, `destination`, `options`, `settingsObject`, `"client"`, true, and with the following steps given `result`:
  1. Run `onComplete` given `result`.
  2. **Assert**: `settingsObject`'s `global object`<sup>p1077</sup> implements `Window`<sup>p922</sup>.
  3. If `result` is not null, optionally `fetch the descendants of and link`<sup>p1091</sup> `result` given `settingsObject`, `destination`, and an empty algorithm.

#### Note

*Generally, performing this step will be beneficial for performance, as it allows pre-loading the modules that will invariably be requested later, via algorithms such as `fetch an external module script graph`<sup>p1089</sup> that fetch the entire graph. However, user agents might wish to skip them in bandwidth-constrained situations, or situations where the relevant fetches are already in flight.*

To **fetch an inline module script graph** given a [string](#) *sourceText*, a [URL](#) *baseURL*, an [environment settings object](#)<sup>p1076</sup> *settingsObject*, a [script fetch options](#)<sup>p1085</sup> *options*, and an algorithm *onComplete*, run these steps. *onComplete* must be an algorithm accepting null (on failure) or a [module script](#)<sup>p1085</sup> (on success).

1. Let *script* be the result of [creating a JavaScript module script](#)<sup>p1093</sup> using *sourceText*, *settingsObject*, *baseURL*, and *options*.
2. [Fetch the descendants of and link](#)<sup>p1091</sup> *script*, given *settingsObject*, "*script*", and *onComplete*.

To **fetch a module worker script graph** given a [URL](#) *url*, an [environment settings object](#)<sup>p1076</sup> *fetchClient*, a [destination](#) *destination*, a [credentials mode](#)<sup>p1086</sup> *credentialsMode*, an [environment settings object](#)<sup>p1076</sup> *settingsObject*, and an algorithm *onComplete*, [fetch a worklet/module worker script graph](#)<sup>p1090</sup> given *url*, *fetchClient*, *destination*, *credentialsMode*, *settingsObject*, and *onComplete*.

To **fetch a worklet script graph** given a [URL](#) *url*, an [environment settings object](#)<sup>p1076</sup> *fetchClient*, a [destination](#) *destination*, a [credentials mode](#)<sup>p1086</sup> *credentialsMode*, an [environment settings object](#)<sup>p1076</sup> *settingsObject*, a [module responses map](#)<sup>p1248</sup> *moduleResponsesMap*, and an algorithm *onComplete*, [fetch a worklet/module worker script graph](#)<sup>p1090</sup> given *url*, *fetchClient*, *destination*, *credentialsMode*, *settingsObject*, *onComplete*, and the following [perform the fetch hook](#)<sup>p1087</sup> given *request* and [processCustomFetchResponse](#)<sup>p1087</sup>:

1. Let *requestURL* be *request*'s [URL](#).
2. If *moduleResponsesMap*[*requestURL*] is "fetching", wait [in parallel](#)<sup>p43</sup> until that entry's value changes, then [queue a task](#)<sup>p1125</sup> on the [networking task source](#)<sup>p1134</sup> to proceed with running the following steps.
3. If *moduleResponsesMap*[*requestURL*] [exists](#), then:
  1. Let *cached* be *moduleResponsesMap*[*requestURL*].
  2. Run *processCustomFetchResponse* with *cached*[0] and *cached*[1].
  3. Return.
4. [Set](#) *moduleResponsesMap*[*requestURL*] to "fetching".
5. [Fetch](#) *request*, with [processResponseConsumeBody](#) set to the following steps given [response](#) *response* and null, failure, or a [byte sequence](#) *bodyBytes*:
  1. Set *moduleResponsesMap*[*requestURL*] to (*response*, *bodyBytes*).
  2. Run *processCustomFetchResponse* with *response* and *bodyBytes*.

The following algorithms are meant for internal use by this specification only as part of [fetching an external module script graph](#)<sup>p1089</sup> or other similar concepts above, and should not be used directly by other specifications.

This diagram illustrates how these algorithms relate to the ones above, as well as to each other:

To **fetch a worklet/module worker script graph** given a [URL](#) *url*, an [environment settings object](#)<sup>p1076</sup> *fetchClient*, a [destination](#) *destination*, a [credentials mode](#)<sup>p1086</sup> *credentialsMode*, an [environment settings object](#)<sup>p1076</sup> *settingsObject*, an algorithm *onComplete*, and an optional [perform the fetch hook](#)<sup>p1087</sup> *performFetch*, run these steps. *onComplete* must be an algorithm accepting null (on failure) or a [module script](#)<sup>p1085</sup> (on success).

1. Let *options* be a [script fetch options](#)<sup>p1085</sup> whose [cryptographic nonce](#)<sup>p1086</sup> is the empty string, [integrity metadata](#)<sup>p1086</sup> is the empty string, [parser metadata](#)<sup>p1086</sup> is "not-parser-inserted", [credentials mode](#)<sup>p1086</sup> is *credentialsMode*, [referrer policy](#)<sup>p1086</sup> is the empty string, and [fetch priority](#)<sup>p1086</sup> is "auto".
2. [Fetch a single module script](#)<sup>p1091</sup> given *url*, *fetchClient*, *destination*, *options*, *settingsObject*, "client", true, and *onSingleFetchComplete* as defined below. If *performFetch* was given, pass it along as well.

*onSingleFetchComplete* given *result* is the following algorithm:

1. If *result* is null, run *onComplete* given null, and abort these steps.
2. [Fetch the descendants of and link](#)<sup>p1091</sup> *result* given *fetchClient*, *destination*, and *onComplete*. If *performFetch* was given, pass it along as well.

To **fetch the descendants of and link** a [module script](#)<sup>p1085</sup> *moduleScript*, given an [environment settings object](#)<sup>p1076</sup> *fetchClient*, a [destination](#) *destination*, an algorithm *onComplete*, and an optional [perform the fetch hook](#)<sup>p1087</sup> *performFetch*, run these steps. *onComplete* must be an algorithm accepting null (on failure) or a [module script](#)<sup>p1085</sup> (on success).

1. Let *record* be *moduleScript*'s [record](#)<sup>p1084</sup>.
2. If *record* is null, then:
  1. Set *moduleScript*'s [error to rethrow](#)<sup>p1084</sup> to *moduleScript*'s [parse error](#)<sup>p1273</sup>.
  2. Run *onComplete* given *moduleScript*.
  3. Return.
3. Let *state* be [Record](#) { [\[\[ParseError\]\]](#): null, [\[\[Destination\]\]](#): *destination*, [\[\[PerformFetch\]\]](#): null, [\[\[FetchClient\]\]](#): *fetchClient* }.
4. If *performFetch* was given, set *state*.[\[\[PerformFetch\]\]](#) to *performFetch*.
5. Let *loadingPromise* be *record*.[LoadRequestedModules](#)(*state*).

#### Note

*This step will recursively load all the module transitive dependencies.*

6. [Upon fulfillment](#) of *loadingPromise*, run the following steps:

1. Perform *record*.[Link](#)().

#### Note

*This step will recursively call [Link](#) on all of the module's unlinked dependencies.*

If this throws an exception, catch it, and set *moduleScript*'s [error to rethrow](#)<sup>p1084</sup> to that exception.

2. Run *onComplete* given *moduleScript*.

7. [Upon rejection](#) of *loadingPromise*, run the following steps:

1. If *state*.[\[\[ParseError\]\]](#) is not null, set *moduleScript*'s [error to rethrow](#)<sup>p1084</sup> to *state*.[\[\[ParseError\]\]](#) and run *onComplete* given *moduleScript*.
2. Otherwise, run *onComplete* given null.

#### Note

**state*.[\[\[ParseError\]\]](#) is null when *loadingPromise* is rejected due to a loading error.*

To **fetch a single module script**, given a [URL](#) *url*, an [environment settings object](#)<sup>p1076</sup> *fetchClient*, a [destination](#) *destination*, a [script fetch options](#)<sup>p1085</sup> *options*, an [environment settings object](#)<sup>p1076</sup> *settingsObject*, a [referrer](#) *referrer*, an optional [ModuleRequest Record](#) *moduleRequest*, a boolean [isTopLevel](#)<sup>p1087</sup>, an algorithm *onComplete*, and an optional [perform the fetch hook](#)<sup>p1087</sup> *performFetch*, run these steps. *onComplete* must be an algorithm accepting null (on failure) or a [module script](#)<sup>p1085</sup> (on success).

1. Let *moduleType* be "javascript-or-wasm".
2. If *moduleRequest* was given, then set *moduleType* to the result of running the [module type from module request](#)<sup>p1095</sup> steps given *moduleRequest*.
3. [Assert](#): the result of running the [module type allowed](#)<sup>p1095</sup> steps given *moduleType* and *settingsObject* is true. Otherwise, we would not have reached this point because a failure would have been raised when inspecting *moduleRequest*.[\[\[Attributes\]\]](#) in [HostLoadImportedModule](#)<sup>p1122</sup> or [fetch a single imported module script](#)<sup>p1093</sup>.
4. Let *moduleMap* be *settingsObject*'s [module map](#)<sup>p1076</sup>.
5. If *moduleMap*[(*url*, *moduleType*)] is "fetching", wait [in parallel](#)<sup>p43</sup> until that entry's value changes, then [queue a task](#)<sup>p1125</sup> on

the [networking task source](#)<sup>p1134</sup> to proceed with running the following steps.

6. If `moduleMap[(url, moduleType)]` [exists](#), run `onComplete` given `moduleMap[(url, moduleType)]`, and return.
7. [Set](#) `moduleMap[(url, moduleType)]` to "fetching".
8. Let `request` be a new [request](#) whose [URL](#) is `url`, [mode](#) is "cors", [referrer](#) is `referrer`, and [client](#) is `fetchClient`.
9. Set `request`'s [destination](#) to the result of running the [fetch destination from module type](#)<sup>p1095</sup> steps given `destination` and `moduleType`.
10. If `destination` is "worker", "sharedworker", or "serviceworker", and `isTopLevel` is true, then set `request`'s [mode](#) to "same-origin".
11. Set `request`'s [initiator type](#) to "script".
12. [Set up the module script request](#)<sup>p1086</sup> given `request` and `options`.
13. If `performFetch` was given, run `performFetch` with `request`, `isTopLevel`, and with `processResponseConsumeBody` as defined below.

Otherwise, [fetch](#) `request` with [processResponseConsumeBody](#) set to `processResponseConsumeBody` as defined below.

In both cases, let `processResponseConsumeBody` given [response](#) `response` and null, failure, or a [byte sequence](#) `bodyBytes` be the following algorithm:

#### Note

*response is always [CORS-same-origin](#)<sup>p98</sup>.*

1. If any of the following are true:
  - `bodyBytes` is null or failure; or
  - `response`'s [status](#) is not an [ok status](#),then [set](#) `moduleMap[(url, moduleType)]` to null, run `onComplete` given null, and abort these steps.
2. Let `mimeType` be the result of [extracting a MIME type](#) from `response`'s [header list](#).
3. Let `moduleScript` be null.
4. Let `referrerPolicy` be the result of [parsing the `Referrer-Policy` header](#) given `response`. [\[REFERRERPOLICY\]](#)<sup>p1481</sup>
5. If `referrerPolicy` is not the empty string, set `options`'s [referrer policy](#)<sup>p1086</sup> to `referrerPolicy`.
6. If `mimeType`'s [essence](#) is "[application/wasm](#)<sup>p1473</sup>" and `moduleType` is "javascript-or-wasm", then set `moduleScript` to the result of [creating a WebAssembly module script](#)<sup>p1094</sup> given `bodyBytes`, `settingsObject`, `response`'s [URL](#), and `options`.
7. Otherwise:
  1. Let `sourceText` be the result of [UTF-8 decoding](#) `bodyBytes`.
  2. If `mimeType` is a [JavaScript MIME type](#) and `moduleType` is "javascript-or-wasm", then set `moduleScript` to the result of [creating a JavaScript module script](#)<sup>p1093</sup> given `sourceText`, `settingsObject`, `response`'s [URL](#), and `options`.
  3. If the [MIME type essence](#) of `mimeType` is "[text/css](#)<sup>p1474</sup>" and `moduleType` is "css", then set `moduleScript` to the result of [creating a CSS module script](#)<sup>p1094</sup> given `sourceText` and `settingsObject`.
  4. If `mimeType` is a [JSON MIME type](#) and `moduleType` is "json", then set `moduleScript` to the result of [creating a JSON module script](#)<sup>p1095</sup> given `sourceText` and `settingsObject`.
8. [Set](#) `moduleMap[(url, moduleType)]` to `moduleScript`, and run `onComplete` given `moduleScript`.

#### Note

*It is intentional that the [module map](#)<sup>p1119</sup> is keyed by the [request URL](#), whereas the [base URL](#)<sup>p1085</sup> for the [module script](#)<sup>p1085</sup> is set to the [response URL](#). The former is used to deduplicate fetches, while the latter is used for URL resolution.*

To **fetch a single imported module script**, given a [URL](#) *url*, an [environment settings object](#)<sup>p1076</sup> *fetchClient*, a [destination](#) *destination*, a [script fetch options](#)<sup>p1085</sup> *options*, an [environment settings object](#)<sup>p1076</sup> *settingsObject*, a [referrer](#) *referrer*, a [ModuleRequest Record](#) *moduleRequest*, an algorithm *onComplete*, and an optional [perform the fetch hook](#)<sup>p1087</sup> *performFetch*, run these steps. *onComplete* must be an algorithm accepting null (on failure) or a [module script](#)<sup>p1085</sup> (on success).

1. **Assert**: *moduleRequest*.[[Attributes]] does not contain any [Record](#) entry such that *entry*.[[Key]] is not "type", because we only asked for "type" attributes in [HostGetSupportedImportAttributes](#)<sup>p1121</sup>.
2. Let *moduleType* be the result of running the [module type from module request](#)<sup>p1095</sup> steps given *moduleRequest*.
3. If the result of running the [module type allowed](#)<sup>p1095</sup> steps given *moduleType* and *settingsObject* is false, then run *onComplete* given null, and return.
4. **Fetch a single module script**<sup>p1091</sup> given *url*, *fetchClient*, *destination*, *options*, *settingsObject*, *referrer*, *moduleRequest*, false, and *onComplete*. If *performFetch* was given, pass it along as well.

#### 8.1.4.3 Creating scripts <sup>p1093</sup>

To **create a classic script**, given a [string](#) *source*, an [environment settings object](#)<sup>p1076</sup> *settings*, a [URL](#) *baseURL*, a [script fetch options](#)<sup>p1085</sup> *options*, an optional boolean *mutedErrors* (default false), and an optional [URL-or-null sourceURLForWindowScripts](#) (default null):

1. If *mutedErrors* is true, then set *baseURL* to [about:blank](#)<sup>p53</sup>.

#### Note

*When mutedErrors is true, baseURL is the script's [CORS-cross-origin](#)<sup>p98</sup> response's url, which shouldn't be exposed to JavaScript. Therefore, baseURL is sanitized here.*

2. If [scripting is disabled](#)<sup>p1083</sup> for *settings*, then set *source* to the empty string.
3. Let *script* be a new [classic script](#)<sup>p1085</sup> that this algorithm will subsequently initialize.
4. Set *script*'s [settings object](#)<sup>p1084</sup> to *settings*.
5. Set *script*'s [base URL](#)<sup>p1085</sup> to *baseURL*.
6. Set *script*'s [fetch options](#)<sup>p1085</sup> to *options*.
7. Set *script*'s [muted errors](#)<sup>p1085</sup> to *mutedErrors*.
8. Set *script*'s [parse error](#)<sup>p1084</sup> and [error to rethrow](#)<sup>p1084</sup> to null.
9. **Record classic script creation time** given *script* and *sourceURLForWindowScripts*.
10. Let *result* be [ParseScript](#)(*source*, *settings*'s [realm](#)<sup>p1077</sup>, *script*).

#### Note

*Passing script as the last parameter here ensures *result*.[[HostDefined]] will be script.*

11. If *result* is a [list](#) of errors, then:
  1. Set *script*'s [parse error](#)<sup>p1084</sup> and its [error to rethrow](#)<sup>p1084</sup> to *result*[0].
  2. Return *script*.
12. Set *script*'s [record](#)<sup>p1084</sup> to *result*.
13. Return *script*.

To **create a JavaScript module script**, given a [string](#) *source*, an [environment settings object](#)<sup>p1076</sup> *settings*, a [URL](#) *baseURL*, and a [script fetch options](#)<sup>p1085</sup> *options*:

1. If [scripting is disabled](#)<sup>p1083</sup> for *settings*, then set *source* to the empty string.
2. Let *script* be a new [module script](#)<sup>p1085</sup> that this algorithm will subsequently initialize.

3. Set *script*'s [settings object](#)<sup>p1084</sup> to *settings*.
4. Set *script*'s [base URL](#)<sup>p1085</sup> to *baseURL*.
5. Set *script*'s [fetch options](#)<sup>p1085</sup> to *options*.
6. Set *script*'s [parse error](#)<sup>p1084</sup> and [error to rethrow](#)<sup>p1084</sup> to null.
7. Let *result* be [ParseModule](#)(*source*, *settings*'s [realm](#)<sup>p1077</sup>, *script*).

**Note**

*Passing script as the last parameter here ensures result.[[HostDefined]] will be script.*

8. If *result* is a [list](#) of errors, then:
  1. Set *script*'s [parse error](#)<sup>p1084</sup> to *result*[0].
  2. Return *script*.
9. Set *script*'s [record](#)<sup>p1084</sup> to *result*.
10. Return *script*.

To **create a WebAssembly module script**, given a [byte sequence](#) *bodyBytes*, an [environment settings object](#)<sup>p1076</sup> *settings*, a [URL](#) *baseURL*, and a [script fetch options](#)<sup>p1085</sup> *options*:

1. If [scripting is disabled](#)<sup>p1083</sup> for *settings*, then set *bodyBytes* to the byte sequence 0x00 0x61 0x73 0x6d 0x01 0x00 0x00 0x00.

**Note**

*This byte sequence corresponds to an empty WebAssembly module with only the magic bytes and version number provided.*

2. Let *script* be a new [module script](#)<sup>p1085</sup> that this algorithm will subsequently initialize.
3. Set *script*'s [settings object](#)<sup>p1084</sup> to *settings*.
4. Set *script*'s [base URL](#)<sup>p1085</sup> to *baseURL*.
5. Set *script*'s [fetch options](#)<sup>p1085</sup> to *options*.
6. Set *script*'s [parse error](#)<sup>p1084</sup> and [error to rethrow](#)<sup>p1084</sup> to null.
7. Let *result* be the result of [parsing a WebAssembly module](#) given *bodyBytes*, *settings*'s [realm](#)<sup>p1077</sup>, and *script*.

**Note**

*Passing script as the last parameter here ensures result.[[HostDefined]] will be script.*

8. If the previous step threw an error *error*, then:
  1. Set *script*'s [parse error](#)<sup>p1084</sup> to *error*.
  2. Return *script*.
9. Set *script*'s [record](#)<sup>p1084</sup> to *result*.
10. Return *script*.

**Note**

WebAssembly JavaScript Interface: ESM Integration specifies the hooks for the WebAssembly integration with ECMA-262 module loading. This includes support both for direct dependency imports, as well as for source phase imports, which support virtualization and multi-instantiation. [\[WASMESM\]](#)<sup>p1483</sup>

To **create a CSS module script**, given a string *source* and an [environment settings object](#)<sup>p1076</sup> *settings*:

1. Let *script* be a new [module script](#)<sup>p1085</sup> that this algorithm will subsequently initialize.

2. Set *script*'s [settings object](#)<sup>p1084</sup> to *settings*.
3. Set *script*'s [base URL](#)<sup>p1085</sup> and [fetch options](#)<sup>p1085</sup> to null.
4. Set *script*'s [parse error](#)<sup>p1084</sup> and [error to rethrow](#)<sup>p1084</sup> to null.
5. Let *sheet* be the result of running the steps to [create a constructed CSSStyleSheet](#) with an empty dictionary as the argument.
6. Run the steps to [synchronously replace the rules of a CSSStyleSheet](#) on *sheet* given *source*.

If this throws an exception, catch it, and set *script*'s [parse error](#)<sup>p1084</sup> to that exception, and return *script*.

#### Note

*The steps to [synchronously replace the rules of a CSSStyleSheet](#) will throw if *source* contains any @import rules. This is by-design for now because there is not yet an agreement on how to handle these for CSS module scripts; therefore they are blocked altogether until a consensus is reached.*

7. Set *script*'s [record](#)<sup>p1084</sup> to the result of [CreateDefaultExportSyntheticModule](#)(*sheet*).
8. Return *script*.

To **create a JSON module script**, given a string *source* and an [environment settings object](#)<sup>p1076</sup> *settings*:

1. Let *script* be a new [module script](#)<sup>p1085</sup> that this algorithm will subsequently initialize.
2. Set *script*'s [settings object](#)<sup>p1084</sup> to *settings*.
3. Set *script*'s [base URL](#)<sup>p1085</sup> and [fetch options](#)<sup>p1085</sup> to null.
4. Set *script*'s [parse error](#)<sup>p1084</sup> and [error to rethrow](#)<sup>p1084</sup> to null.
5. Let *result* be [ParseJSONModule](#)(*source*).

If this throws an exception, catch it, and set *script*'s [parse error](#)<sup>p1084</sup> to that exception, and return *script*.

6. Set *script*'s [record](#)<sup>p1084</sup> to *result*.
7. Return *script*.

The **module type from module request** steps, given a [ModuleRequest Record](#) *moduleRequest*, are as follows:

1. Let *moduleType* be "javascript-or-wasm".
2. If *moduleRequest*.[[Attributes]] has a [Record](#) entry such that entry.[[Key]] is "type", then:
  1. If entry.[[Value]] is "javascript-or-wasm", then set *moduleType* to null.

#### Note

*This specification uses the "javascript-or-wasm" module type internally for [JavaScript module scripts](#)<sup>p1085</sup> or [WebAssembly module scripts](#)<sup>p1085</sup>, so this step is needed to prevent modules from being imported using a "javascript-or-wasm" type attribute (a null moduleType will cause the [module type allowed](#)<sup>p1095</sup> check to fail).*

2. Otherwise, set *moduleType* to entry.[[Value]].
3. Return *moduleType*.

The **module type allowed** steps, given a [string](#) *moduleType* and an [environment settings object](#)<sup>p1076</sup> *settings*, are as follows:

1. If *moduleType* is not "javascript-or-wasm", "css", or "json", then return false.
2. If *moduleType* is "css" and the [CSSStyleSheet](#) interface is not [exposed](#) in *settings*'s [realm](#)<sup>p1077</sup>, then return false.
3. Return true.

The **fetch destination from module type** steps, given a [destination](#) *defaultDestination* and a [string](#) *moduleType*, are as follows:

1. If *moduleType* is "json", then return "json".

2. If *moduleType* is "css", then return "style".
3. Return *defaultDestination*.

#### 8.1.4.4 Calling scripts <sup>§ p10</sup><sub>96</sub>

To **run a classic script** given a [classic script](#)<sup>p1085</sup> *script* and an optional boolean *rethrow errors* (default false):

1. Let *settings* be the [settings object](#)<sup>p1084</sup> of *script*.
  2. [Check if we can run script](#)<sup>p1097</sup> with *settings*. If this returns "do not run" then return [NormalCompletion](#)(empty).
  3. [Record classic script execution start time](#) given *script*.
  4. [Prepare to run script](#)<sup>p1097</sup> given *settings*.
  5. Let *evaluationStatus* be null.
  6. If *script*'s [error to rethrow](#)<sup>p1084</sup> is not null, then set *evaluationStatus* to Completion { [[Type]]: throw, [[Value]]: *script*'s [error to rethrow](#)<sup>p1084</sup>, [[Target]]: empty }.
  7. Otherwise, set *evaluationStatus* to [ScriptEvaluation](#)(*script*'s [record](#)<sup>p1084</sup>).
- If [ScriptEvaluation](#) does not complete because the user agent has [aborted the running script](#)<sup>p1097</sup>, leave *evaluationStatus* as null.
8. If *evaluationStatus* is an [abrupt completion](#), then:
    1. If *rethrow errors* is true and *script*'s [muted errors](#)<sup>p1085</sup> is false, then:
      1. [Clean up after running script](#)<sup>p1097</sup> with *settings*.
      2. Rethrow *evaluationStatus*.[[Value]].
    2. If *rethrow errors* is true and *script*'s [muted errors](#)<sup>p1085</sup> is true, then:
      1. [Clean up after running script](#)<sup>p1097</sup> with *settings*.
      2. Throw a ["NetworkError" DOMException](#).
    3. Otherwise, *rethrow errors* is false. Perform the following steps:
      1. [Report an exception](#)<sup>p1098</sup> given by *evaluationStatus*.[[Value]] for *script*'s [settings object](#)<sup>p1084</sup>'s [global object](#)<sup>p1077</sup>.
      2. [Clean up after running script](#)<sup>p1097</sup> with *settings*.
      3. Return *evaluationStatus*.
  9. [Clean up after running script](#)<sup>p1097</sup> with *settings*.
  10. If *evaluationStatus* is a normal completion, then return *evaluationStatus*.
  11. If we've reached this point, *evaluationStatus* was left as null because the script was [aborted prematurely](#)<sup>p1097</sup> during evaluation. Return Completion { [[Type]]: throw, [[Value]]: a new ["QuotaExceededError" DOMException](#), [[Target]]: empty }.

To **run a module script** given a [module script](#)<sup>p1085</sup> *script* and an optional boolean *preventErrorReporting* (default false):

1. Let *settings* be the [settings object](#)<sup>p1084</sup> of *script*.
2. [Check if we can run script](#)<sup>p1097</sup> with *settings*. If this returns "do not run", then return [a promise resolved with](#) undefined.
3. [Record module script execution start time](#) given *script*.
4. [Prepare to run script](#)<sup>p1097</sup> given *settings*.
5. Let *evaluationPromise* be null.
6. If *script*'s [error to rethrow](#)<sup>p1084</sup> is not null, then set *evaluationPromise* to [a promise rejected with](#) *script*'s [error to rethrow](#)<sup>p1084</sup>.

7. Otherwise:

1. Let *record* be *script*'s [record](#)<sup>p1084</sup>.
2. Set *evaluationPromise* to *record*.[Evaluate](#)(*record*).

**Note**

*This step will recursively evaluate all of the module's dependencies.*

If [Evaluate](#) fails to complete as a result of the user agent [aborting the running script](#)<sup>p1097</sup>, then set *evaluationPromise* to [a promise rejected with](#) a new ["QuotaExceededError"](#) [DOMException](#).

8. If *preventErrorReporting* is false, then [upon rejection](#) of *evaluationPromise* with *reason*, [report an exception](#)<sup>p1098</sup> given by *reason* for *script*'s [settings object](#)<sup>p1084</sup>'s [global object](#)<sup>p1077</sup>.
9. [Clean up after running script](#)<sup>p1097</sup> with *settings*.
10. Return *evaluationPromise*.

The steps to **check if we can run script** with an [environment settings object](#)<sup>p1076</sup> *settings* are as follows. They return either "run" or "do not run".

1. If the [global object](#)<sup>p1077</sup> specified by *settings* is a [Window](#)<sup>p922</sup> object whose [Document](#)<sup>p139</sup> object is not [fully active](#)<sup>p1003</sup>, then return "do not run".
2. If [scripting is disabled](#)<sup>p1083</sup> for *settings*, then return "do not run".
3. Return "run".

The steps to **prepare to run script** with an [environment settings object](#)<sup>p1076</sup> *settings* are as follows:

1. Push *settings*'s [realm execution context](#)<sup>p1076</sup> onto the [JavaScript execution context stack](#); it is now the [running JavaScript execution context](#).
2. Add *settings* to the [surrounding agent](#)'s [event loop](#)<sup>p1123</sup>'s [currently running task](#)<sup>p1124</sup>'s [script evaluation environment settings object set](#)<sup>p1124</sup>.

The steps to **clean up after running script** with an [environment settings object](#)<sup>p1076</sup> *settings* are as follows:

1. [Assert](#): *settings*'s [realm execution context](#)<sup>p1076</sup> is the [running JavaScript execution context](#).
2. Remove *settings*'s [realm execution context](#)<sup>p1076</sup> from the [JavaScript execution context stack](#).
3. If the [JavaScript execution context stack](#) is now empty, [perform a microtask checkpoint](#)<sup>p1131</sup>. (If this runs scripts, these algorithms will be invoked reentrantly.)

**Note**

*These algorithms are not invoked by one script directly calling another, but they can be invoked reentrantly in an indirect manner, e.g. if a script dispatches an event which has event listeners registered.*

The **running script** is the [script](#)<sup>p1084</sup> in the `[[HostDefined]]` field in the `ScriptOrModule` component of the [running JavaScript execution context](#).

#### 8.1.4.5 Killing scripts § p1097

Although the JavaScript specification does not account for this possibility, it's sometimes necessary to **abort a running script**. This causes any [ScriptEvaluation](#) or [Source Text Module Record Evaluate](#) invocations to cease immediately, emptying the [JavaScript execution context stack](#) without triggering any of the normal mechanisms like `finally` blocks. [\[JAVASCRIPT\]](#)<sup>p1479</sup>

User agents may impose resource limitations on scripts, for example CPU quotas, memory limits, total execution time limits, or bandwidth limitations. When a script exceeds a limit, the user agent may either throw a ["QuotaExceededError"](#) [DOMException](#), [abort the script](#)<sup>p1097</sup> without an exception, prompt the user, or throttle script execution.

#### Example

For example, the following script never terminates. A user agent could, after waiting for a few seconds, prompt the user to either terminate the script or let it continue.

```
<script>
  while (true) { /* loop */ }
</script>
```

User agents are encouraged to allow users to disable scripting whenever the user is prompted either by a script (e.g. using the [window.alert\(\)](#)<sup>p1167</sup> API) or because of a script's actions (e.g. because it has exceeded a time limit).

If scripting is disabled while a script is executing, the script should be terminated immediately.

User agents may allow users to specifically disable scripts just for the purposes of closing a [browsing context](#)<sup>p998</sup>.

#### Example

For example, the prompt mentioned in the example above could also offer the user with a mechanism to just close the page entirely, without running any [unload](#)<sup>p1472</sup> event handlers.

### 8.1.4.6 Runtime script errors <sup>p1098</sup>

For web developers (non-normative)

**self.reportError**<sup>p1099</sup>(e)

Dispatches an [error](#)<sup>p1471</sup> event at the global object for the given value e, in the same fashion as an unhandled exception.

To **extract error information** from a JavaScript value *exception*:

1. Let *attributes* be an empty [map](#) keyed by IDL attributes.
2. Set *attributes*[[error](#)<sup>p1100</sup>] to *exception*.
3. Set *attributes*[[message](#)<sup>p1100</sup>], *attributes*[[filename](#)<sup>p1100</sup>], *attributes*[[lineno](#)<sup>p1100</sup>], and *attributes*[[colno](#)<sup>p1100</sup>] to [implementation-defined](#) values derived from *exception*.

#### Note

*Browsers implement behavior not specified here or in the JavaScript specification to gather values which are helpful, including in unusual cases (e.g., eval). In the future, this might be specified in greater detail.*

4. Return *attributes*.

To **report an exception** *exception* which is a JavaScript value, for a particular [global object](#)<sup>p1076</sup> *global* and optional boolean **omitError** (default false):

1. Let *notHandled* be true.
2. Let *errorInfo* be the result of [extracting error information](#)<sup>p1098</sup> from *exception*.
3. Let *script* be a [script](#)<sup>p1084</sup> found in an [implementation-defined](#) way, or null. This should usually be the [running script](#)<sup>p1097</sup> (most notably during [run a classic script](#)<sup>p1096</sup>).

#### Note

*Implementations have not yet settled on interoperable behavior for which script is used to determine whether errors are muted in less common cases.*

4. If *script* is a [classic script](#)<sup>p1085</sup> and *script*'s [muted errors](#)<sup>p1085</sup> is true, then set *errorInfo*[[error](#)<sup>p1100</sup>] to null, *errorInfo*[[message](#)<sup>p1100</sup>] to "Script error.", *errorInfo*[[filename](#)<sup>p1100</sup>] to the empty string, *errorInfo*[[lineno](#)<sup>p1100</sup>] to 0, and *errorInfo*[[colno](#)<sup>p1100</sup>] to 0.
5. If *omitError* is true, then set *errorInfo*[[error](#)<sup>p1100</sup>] to null.

6. If *global* is not [in error reporting mode](#)<sup>p1077</sup>, then:

1. Set *global*'s [in error reporting mode](#)<sup>p1077</sup> to true.
2. If *global* implements [EventTarget](#), then set *notHandled* to the result of [firing an event](#) named [error](#)<sup>p1471</sup> at *global*, using [ErrorEvent](#)<sup>p1099</sup>, with the [cancelable](#) attribute initialized to true, and additional attributes initialized according to *errorInfo*.

**Note**

*Returning true in an event handler cancels the event per [the event handler processing algorithm](#)<sup>p1140</sup>.*

3. Set *global*'s [in error reporting mode](#)<sup>p1077</sup> to false.

7. If *notHandled* is true, then:

1. Set *errorInfo*[[error](#)<sup>p1100</sup>] to null.
2. If *global* implements [DedicatedWorkerGlobalScope](#)<sup>p1230</sup>, [queue a global task](#)<sup>p1125</sup> on the [DOM manipulation task source](#)<sup>p1134</sup> with the *global*'s associated [Worker](#)<sup>p1236</sup>'s [relevant global object](#)<sup>p1083</sup> to run these steps:
  1. Let *workerObject* be the [Worker](#)<sup>p1236</sup> object associated with *global*.
  2. Set *notHandled* be the result of [firing an event](#) named [error](#)<sup>p1471</sup> at *workerObject*, using [ErrorEvent](#)<sup>p1099</sup>, with the [cancelable](#) attribute initialized to true, and additional attributes initialized according to *errorInfo*.
  3. If *notHandled* is true, then [report](#)<sup>p1098</sup> exception for *workerObject*'s [relevant global object](#)<sup>p1083</sup> with [omitError](#)<sup>p1098</sup> set to true.

**Note**

*The actual exception value will not be available in the owner realm, but the user agent still carries through enough information to set the message, filename, and other attributes, as well as potentially report to a developer console.*

8. Otherwise, the user agent may report exception to a developer console.

If the implicit port connecting a worker to its [Worker](#)<sup>p1236</sup> object has been disentangled (i.e. if the parent worker has been terminated), then the user agent must act as if the [Worker](#)<sup>p1236</sup> object had no [error](#)<sup>p1471</sup> event handler and as if that worker's [onerror](#)<sup>p1229</sup> attribute was null, but must otherwise act as described above.

**Note**

*Thus, error reports propagate up to the chain of dedicated workers up to the original [Document](#)<sup>p130</sup>, even if some of the workers along this chain have been terminated and garbage collected.*

Previous revisions of this standard defined an algorithm to **report the exception**. As part of [issue #958](#), this has been superseded by [report an exception](#)<sup>p1098</sup> which behaves differently and takes different inputs. [Issue #10516](#) tracks updating the specification ecosystem.

The [reportError\(e\)](#) method steps are to [report an exception](#)<sup>p1098</sup> e for [this](#).

It is unclear whether [muting](#)<sup>p1085</sup> is applicable here. In Chrome and Safari it is muted, but in Firefox it is not. See also [issue #958](#).

The [ErrorEvent](#)<sup>p1099</sup> interface is defined as follows:

```
IDL [Exposed=*]
interface ErrorEvent : Event {
  constructor(DOMString type, optional ErrorEventInit eventInitDict = {});

  readonly attribute DOMString message;
  readonly attribute USVString filename;
```

```

    readonly attribute unsigned long lineno;
    readonly attribute unsigned long colno;
    readonly attribute any error;
};

dictionary ErrorEventInit : EventInit {
    DOMString message = "";
    USVString filename = "";
    unsigned long lineno = 0;
    unsigned long colno = 0;
    any error;
};

```

The **message** attribute must return the value it was initialized to. It represents the error message.

The **filename** attribute must return the value it was initialized to. It represents the [URL](#) of the script in which the error originally occurred.

The **lineno** attribute must return the value it was initialized to. It represents the line number where the error occurred in the script.

The **colno** attribute must return the value it was initialized to. It represents the column number where the error occurred in the script.

The **error** attribute must return the value it was initialized to. It must initially be initialized to undefined. Where appropriate, it is set to the object representing the error (e.g., the exception object in the case of an uncaught exception).

#### 8.1.4.7 Unhandled promise rejections §<sup>p1100</sup>

In addition to synchronous [runtime script errors](#)<sup>p1098</sup>, scripts may experience asynchronous promise rejections, tracked via the [unhandledrejection](#)<sup>p1472</sup> and [rejectionhandled](#)<sup>p1472</sup> events. Tracking these rejections is done via the [HostPromiseRejectionTracker](#)<sup>p1115</sup> abstract operation, but reporting them is defined here.

To **notify about rejected promises** given a [global object](#)<sup>p1076</sup> *global*:

1. Let *list* be a [clone](#) of *global*'s [about-to-be-notified rejected promises list](#)<sup>p1077</sup>.
2. If *list* is [empty](#), then return.
3. [Empty](#) *global*'s [about-to-be-notified rejected promises list](#)<sup>p1077</sup>.
4. [Queue a global task](#)<sup>p1125</sup> on the [DOM manipulation task source](#)<sup>p1134</sup> given *global* to run the following step:
  1. [For each](#) promise *p* of *list*:
    1. If *p*.[[PromisesHandled]] is true, then [continue](#).
    2. Let *notCanceled* be the result of [firing an event](#) named [unhandledrejection](#)<sup>p1472</sup> at *global*, using [PromiseRejectionEvent](#)<sup>p1100</sup>, with the [cancelable](#) attribute initialized to true, the [promise](#)<sup>p1101</sup> attribute initialized to *p*, and the [reason](#)<sup>p1101</sup> attribute initialized to *p*.[[PromiseResult]].
    3. If *notCanceled* is true, then the user agent may report *p*.[[PromiseResult]] to a developer console.
    4. If *p*.[[PromisesHandled]] is false, then [append](#) *p* to *global*'s [outstanding rejected promises weak set](#)<sup>p1077</sup>.

The [PromiseRejectionEvent](#)<sup>p1100</sup> interface is defined as follows:

```

IDL [Exposed=*)
interface PromiseRejectionEvent : Event {
    constructor(DOMString type, PromiseRejectionEventInit eventInitDict);

    readonly attribute object promise;
    readonly attribute any reason;
};

```

```
dictionary PromiseRejectionEventInit : EventInit {
  required object promise;
  any reason;
};
```

The **promise** attribute must return the value it was initialized to. It represents the promise which this notification is about.

#### Note

Because of how Web IDL conversion rules for **Promise**<T> types always wrap the input into a new promise, the **promise**<sup>p1101</sup> attribute is of type **object** instead, which is more appropriate for representing an opaque handle to the original promise object.

The **reason** attribute must return the value it was initialized to. It represents the rejection reason for the promise.

### 8.1.4.8 Import map parse results <sup>§p1101</sup>

An **import map parse result** is a **struct** that is similar to a **script**<sup>p1084</sup>, and also can be stored in a **script**<sup>p652</sup> element's **result**<sup>p659</sup>, but is not counted as a **script**<sup>p1084</sup> for other purposes. It has the following **items**:

#### An import map

An **import map**<sup>p1107</sup> or null.

#### An error to rethrow

A JavaScript value representing an error that will prevent using this import map, when non-null.

To **create an import map parse result** given a **string** *input* and a **URL** *baseURL*:

1. Let *result* be an **import map parse result**<sup>p1101</sup> whose **import map**<sup>p1101</sup> is null and whose **error to rethrow**<sup>p1101</sup> is null.
2. **Parse an import map string**<sup>p1107</sup> given *input* and *baseURL*, catching any exceptions. If this threw an exception, then set *result*'s **error to rethrow**<sup>p1101</sup> to that exception. Otherwise, set *result*'s **import map**<sup>p1101</sup> to the return value.
3. Return *result*.

To **register an import map** given a **Window**<sup>p922</sup> *global* and an **import map parse result**<sup>p1101</sup> *result*:

1. If *result*'s **error to rethrow**<sup>p1101</sup> is not null, then **report an exception**<sup>p1098</sup> given by *result*'s **error to rethrow**<sup>p1101</sup> for *global* and return.
2. **Merge existing and new import maps**<sup>p1109</sup>, given *global* and *result*'s **import map**<sup>p1101</sup>.

### 8.1.5 Module specifier resolution <sup>§p1101</sup>

#### 8.1.5.1 The resolution algorithm <sup>§p1101</sup>

The **resolve a module specifier**<sup>p1102</sup> algorithm is the primary entry point for converting module specifier strings into **URLs**. When no **import maps**<sup>p1107</sup> are involved, it is relatively straightforward, and reduces to **resolving a URL-like module specifier**<sup>p1103</sup>.

When there is a non-empty **import map**<sup>p1107</sup> present, the behavior is more complex. It checks candidate entries from all applicable **module specifier maps**<sup>p1107</sup>, from most-specific to least-specific **scopes**<sup>p1107</sup> (falling back to the top-level unscoped **imports**<sup>p1107</sup>), and from most-specific to least-specific prefixes. For each candidate, the **resolve an imports match**<sup>p1102</sup> algorithm will give on the following results:

- Successful resolution of the specifier to a **URL**. Then the **resolve a module specifier**<sup>p1102</sup> algorithm will return that URL.
- Throwing an exception. Then the **resolve a module specifier**<sup>p1102</sup> algorithm will rethrow that exception, without any further fallbacks.
- Failing to resolve, without an error. In this case the outer **resolve a module specifier**<sup>p1102</sup> algorithm will move on to the next candidate.

In the end, if no successful resolution is found via any of the candidate [module specifier maps](#)<sup>p1107</sup>, [resolve a module specifier](#)<sup>p1102</sup> will throw an exception. Thus the result is always either a [URL](#) or a thrown exception.

To **resolve a module specifier** given a [script](#)<sup>p652</sup>-or-null *referringScript* and a [string](#) *specifier*:

1. Let *settingsObject* and *baseURL* be null.
2. If *referringScript* is not null, then:
  1. Set *settingsObject* to *referringScript*'s [settings object](#)<sup>p1084</sup>.
  2. Set *baseURL* to *referringScript*'s [base URL](#)<sup>p1085</sup>.
3. Otherwise:
  1. **Assert**: there is a [current settings object](#)<sup>p1083</sup>.
  2. Set *settingsObject* to the [current settings object](#)<sup>p1083</sup>.
  3. Set *baseURL* to *settingsObject*'s [API base URL](#)<sup>p1076</sup>.
4. Let *importMap* be an [empty import map](#)<sup>p1107</sup>.
5. If *settingsObject*'s [global object](#)<sup>p1077</sup> implements [Window](#)<sup>p922</sup>, then set *importMap* to *settingsObject*'s [global object](#)<sup>p1077</sup>'s [import map](#)<sup>p1077</sup>.
6. Let *serializedBaseURL* be *baseURL*, [serialized](#).
7. Let *asURL* be the result of [resolving a URL-like module specifier](#)<sup>p1103</sup> given *specifier* and *baseURL*.
8. Let *normalizedSpecifier* be the [serialization](#) of *asURL*, if *asURL* is non-null; otherwise, *specifier*.
9. Let *result* be a [URL](#)-or-null, initially null.
10. **For each** *scopePrefix* → *scopeImports* of *importMap*'s [scopes](#)<sup>p1107</sup>:
  1. If *scopePrefix* is *serializedBaseURL*, or if *scopePrefix* ends with U+002F (/) and *scopePrefix* is a [code unit prefix](#) of *serializedBaseURL*, then:
    1. Let *scopeImportsMatch* be the result of [resolving an imports match](#)<sup>p1102</sup> given *normalizedSpecifier*, *asURL*, and *scopeImports*.
    2. If *scopeImportsMatch* is not null, then set *result* to *scopeImportsMatch*, and **break**.
11. If *result* is null, set *result* be the result of [resolving an imports match](#)<sup>p1102</sup> given *normalizedSpecifier*, *asURL*, and *importMap*'s [imports](#)<sup>p1107</sup>.
12. If *result* is null, set it to *asURL*.

#### Note

By this point, if *result* was null, *specifier* wasn't remapped to anything by *importMap*, but it might have been able to be turned into a URL.

13. If *result* is not null, then:
  1. [Add module to resolved module set](#)<sup>p1107</sup> given *settingsObject*, *serializedBaseURL*, *normalizedSpecifier*, and *asURL*.
  2. Return *result*.
14. Throw a **TypeError** indicating that *specifier* was a bare specifier, but was not remapped to anything by *importMap*.

To **resolve an imports match**, given a [string](#) *normalizedSpecifier*, a [URL](#)-or-null *asURL*, and a [module specifier map](#)<sup>p1107</sup> *specifierMap*:

1. **For each** *specifierKey* → *resolutionResult* of *specifierMap*:
  1. If *specifierKey* is *normalizedSpecifier*, then:
    1. If *resolutionResult* is null, then throw a **TypeError** indicating that resolution of *specifierKey* was blocked by a null entry.

**Note**

This will terminate the entire [resolve a module specifier<sup>p1102</sup>](#) algorithm, without any further fallbacks.

2. **Assert:** *resolutionResult* is a [URL](#).
  3. Return *resolutionResult*.
2. If all of the following are true:
- *specifierKey* ends with U+002F (/);
  - *specifierKey* is a [code unit prefix](#) of *normalizedSpecifier*; and
  - either *asURL* is null, or *asURL* [is special](#),

then:

1. If *resolutionResult* is null, then throw a **TypeError** indicating that the resolution of *specifierKey* was blocked by a null entry.

**Note**

This will terminate the entire [resolve a module specifier<sup>p1102</sup>](#) algorithm, without any further fallbacks.

2. **Assert:** *resolutionResult* is a [URL](#).
3. Let *afterPrefix* be the portion of *normalizedSpecifier* after the initial *specifierKey* prefix.
4. **Assert:** *resolutionResult*, [serialized](#), ends with U+002F (/), as enforced during [parsing<sup>p1107</sup>](#).
5. Let *url* be the result of [URL parsing](#) *afterPrefix* with *resolutionResult*.
6. If *url* is failure, then throw a **TypeError** indicating that resolution of *normalizedSpecifier* was blocked since the *afterPrefix* portion could not be URL-parsed relative to the *resolutionResult* mapped to by the *specifierKey* prefix.

**Note**

This will terminate the entire [resolve a module specifier<sup>p1102</sup>](#) algorithm, without any further fallbacks.

7. **Assert:** *url* is a [URL](#).
8. If the [serialization](#) of *resolutionResult* is not a [code unit prefix](#) of the [serialization](#) of *url*, then throw a **TypeError** indicating that the resolution of *normalizedSpecifier* was blocked due to it backtracking above its prefix *specifierKey*.

**Note**

This will terminate the entire [resolve a module specifier<sup>p1102</sup>](#) algorithm, without any further fallbacks.

9. Return *url*.

2. Return null.

**Note**

The [resolve a module specifier<sup>p1102</sup>](#) algorithm will fall back to a less-specific scope, or to "imports", if possible.

To **resolve a URL-like module specifier**, given a [string](#) *specifier* and a [URL](#) *baseURL*:

1. If *specifier* [starts with](#) ["/"](#), ["./"](#), or ["../"](#), then:
  1. Let *url* be the result of [URL parsing](#) *specifier* with *baseURL*.
  2. If *url* is failure, then return null.

**Example**

One way this could happen is if *specifier* is ["../foo"](#) and *baseURL* is a [data:](#) URL.

3. Return *url*.

#### Note

This includes cases where specifier [starts with "/"](#), i.e., [scheme-relative URLs](#). Thus, url might end up with a different [host](#) than baseUrl.

2. Let url be the result of [URL parsing](#) specifier (with no base URL).
3. If url is failure, then return null.
4. Return url.

#### 8.1.5.2 Import maps § p1104

An [import map](#)<sup>p1107</sup> allows control over module specifier resolution. Import maps are delivered via inline [script](#)<sup>p652</sup> elements with their [type](#)<sup>p653</sup> attribute set to "importmap", and with their [child text content](#) containing a JSON representation of the import map.

A [Document](#)<sup>p130</sup> can have multiple import maps processed, which can happen either before or after any modules have been imported, e.g., via [import\(\)](#) expressions or [script](#)<sup>p652</sup> elements with their [type](#)<sup>p653</sup> attribute set to "module". The [merge existing and new import maps](#)<sup>p1109</sup> algorithm ensures that new import maps cannot define the module resolution for modules that were already defined by past import maps, or for ones that were already resolved.

#### Example

The simplest use of import maps is to globally remap a bare module specifier:

```
{
  "imports": {
    "moment": "/node_modules/moment/src/moment.js"
  }
}
```

This enables statements like `import moment from "moment";` to work, fetching and evaluating the JavaScript module at the `/node_modules/moment/src/moment.js` URL.

#### Example

An import map can remap a class of module specifiers into a class of URLs by using trailing slashes, like so:

```
{
  "imports": {
    "moment/": "/node_modules/moment/src/"
  }
}
```

This enables statements like `import localeData from "moment/locale/zh-cn.js";` to work, fetching and evaluating the JavaScript module at the `/node_modules/moment/src/locale/zh-cn.js` URL. Such trailing-slash mappings are often combined with bare-specifier mappings, e.g.

```
{
  "imports": {
    "moment": "/node_modules/moment/src/moment.js",
    "moment/": "/node_modules/moment/src/"
  }
}
```

so that both the "main module" specified by "moment" and the "submodules" specified by paths such as "moment/locale/zh-cn.js" are available.

#### Example

Bare specifiers are not the only type of module specifiers which import maps can remap. "URL-like" specifiers, i.e., those that are

either parseable as absolute URLs or start with `"/`, `"/`, or `"/`, can be remapped as well:

```
{
  "imports": {
    "https://cdn.example.com/vue/dist/vue.runtime.esm.js": "/node_modules/vue/dist/
vue.runtime.esm.js",
    "/js/app.mjs": "/js/app-8e0d62a03.mjs",
    "../helpers/": "https://cdn.example/helpers/"
  }
}
```

Note how the URL to be remapped, as well as the URL being mapped to, can be specified either as absolute URLs, or as relative URLs starting with `"/`, `"/`, or `"/`. (They cannot be specified as relative URLs without those starting sigils, as those help distinguish from bare module specifiers.) Also note how the [trailing slash mapping](#)<sup>p1104</sup> works in this context as well.

Such remappings operate on the post-canonicalization URL, and do not require a match between the literal strings supplied in the import map key and the imported module specifier. So for example, if this import map was included on `https://example.com/app.html`, then not only would `import "/js/app.mjs"` be remapped, but so would `import "../js/app.mjs"` and `import "../foo/./js/app.mjs"`.

### Example

All previous examples have globally remapped module specifiers, by using the top-level `"imports"` key in the import map. The top-level `"scopes"` key can be used to provide localized remappings, which only apply when the referring module matches a specific URL prefix. For example:

```
{
  "scopes": {
    "/a/" : {
      "moment": "/node_modules/moment/src/moment.js"
    },
    "/b/" : {
      "moment": "https://cdn.example.com/moment/src/moment.js"
    }
  }
}
```

With this import map, the statement `import "moment"` will have different meanings depending on which referrer script contains the statement:

- Inside scripts located under `/a/`, this will import `/node_modules/moment/src/moment.js`.
- Inside scripts located under `/b/`, this will import `https://cdn.example.com/moment/src/moment.js`.
- Inside scripts located under `/c/`, this will fail to resolve and thus throw an exception.

A typical usage of scopes is to allow multiple versions of the "same" module to exist in a web application, with some parts of the module graph importing one version, and other parts importing another version.

### Example

Scopes can overlap each other, and overlap the global `"imports"` specifier map. At resolution time, scopes are consulted in order of most- to least-specific, where specificity is measured by sorting the scopes using the [code unit less than](#) operation. So, for example, `"/scope2/scope3/"` is treated as more specific than `"/scope2/"`, which is treated as more specific than the top-level (unscoped) mappings.

The following import map illustrates this:

```
{
  "imports": {
    "a": "/a-1.mjs",
```

```

    "b": "/b-1.mjs",
    "c": "/c-1.mjs"
  },
  "scopes": {
    "/scope2/": {
      "a": "/a-2.mjs"
    },
    "/scope2/scope3/": {
      "b": "/b-3.mjs"
    }
  }
}

```

This results in the following resolutions (using relative URLs for brevity):

		Specifier		
		"a"	"b"	"c"
Referrer	/scope1/r.mjs	/a-1.mjs	/b-1.mjs	/c-1.mjs
	/scope2/r.mjs	/a-2.mjs	/b-1.mjs	/c-1.mjs
	/scope2/scope3/r.mjs	/a-2.mjs	/b-3.mjs	/c-1.mjs

#### Example

Import maps can also be used to provide modules with integrity metadata to be used in *Subresource Integrity* checks. [\[SRI\]<sup>p1482</sup>](#)

The following import map illustrates this:

```

{
  "imports": {
    "a": "/a-1.mjs",
    "b": "/b-1.mjs",
    "c": "/c-1.mjs"
  },
  "integrity": {
    "/a-1.mjs": "sha384-Li9vy3DqF8tnTXuiaAJuML3ky+er10rcgNR/VqsVpcw+ThHmYcwiB1pb0xEbzJr7",
    "/d-1.mjs": "sha384-MB05IDfYaE6c6Aao94oZrIOiC6CGiSN2n4QUbHNPzk5Xhm0djZLQqTpL0HzTUxk"
  }
}

```

The above example provides integrity metadata to be enforced on the modules `/a-1.mjs` and `/d-1.mjs`, even if the latter is not defined as an import in the map.

The [child text content](#) of a [script<sup>p652</sup>](#) element representing an [import map<sup>p1107</sup>](#) must match the following **import map authoring requirements**:

- It must be valid JSON. [\[JSON\]<sup>p1479</sup>](#)
- The JSON must represent a JSON object, with at most the three keys "imports", "scopes", and "integrity".
- The values corresponding to the "imports", "scopes", and "integrity" keys, if present, must themselves be JSON objects.
- The value corresponding to the "imports" key, if present, must be a [valid module specifier map<sup>p1106</sup>](#).
- The value corresponding to the "scopes" key, if present, must be a JSON object, whose keys are [valid URL strings](#) and whose values are [valid module specifier maps<sup>p1106</sup>](#).
- The value corresponding to the "integrity" key, if present, must be a JSON object, whose keys are [valid URL strings](#) and whose values fit [the requirements of the integrity attribute](#).

A **valid module specifier map** is a JSON object that meets the following requirements:

- All of its keys must be nonempty.
- All of its values must be strings.
- Each value must be either a [valid absolute URL](#) or a [valid URL string](#) that [starts with](#) `"/"`, `"./"`, or `"../"`.
- If a given key [ends with](#) `"/"`, then the corresponding value must also.

### 8.1.5.3 Import map processing model <sup>§ p1107</sup>

Formally, an **import map** is a [struct](#) with three [items](#):

- **imports**, a [module specifier map](#)<sup>p1107</sup>;
- **scopes**, an [ordered map](#) of [URLs](#) to [module specifier maps](#)<sup>p1107</sup>; and
- **integrity**, a [module integrity map](#)<sup>p1107</sup>.

A **module specifier map** is an [ordered map](#) whose [keys](#) are [strings](#) and whose [values](#) are either [URLs](#) or nulls.

A **module integrity map** is an [ordered map](#) whose [keys](#) are [URLs](#) and whose [values](#) are [strings](#) that will be used as [integrity metadata](#).

An **empty import map** is an [import map](#)<sup>p1107</sup> with its [imports](#)<sup>p1107</sup> and [scopes](#)<sup>p1107</sup> both being empty maps.

A **specifier resolution record** is a [struct](#). It has the following [items](#):

#### A **serialized base URL**

A [string](#)-or-null that represents the base URL of the specifier, when one exists.

#### A **specifier**

A [string](#) representing the specifier.

#### A **specifier as a URL**

A [URL](#)-or-null that represents the URL in case of a URL-like module specifier.

#### Note

*Implementations can replace [specifier as a URL](#)<sup>p1107</sup> with a boolean that indicates that the specifier is either bare or URL-like that [is special](#).*

To **add module to resolved module set** given an [environment settings object](#)<sup>p1076</sup> *settingsObject*, a [string](#) *serializedBaseURL*, a [string](#) *normalizedSpecifier*, and a [URL](#)-or-null *asURL*:

1. Let *global* be *settingsObject*'s [global object](#)<sup>p1077</sup>.
2. If *global* does not implement [Window](#)<sup>p922</sup>, then return.
3. Let *record* be a new [specifier resolution record](#)<sup>p1107</sup>, with [serialized base URL](#)<sup>p1107</sup> set to *serializedBaseURL*, [specifier](#)<sup>p1107</sup> set to *normalizedSpecifier*, and [specifier as a URL](#)<sup>p1107</sup> set to *asURL*.
4. [Append](#) *record* to *global*'s [resolved module set](#)<sup>p1077</sup>.

To **parse an import map string**, given a [string](#) *input* and a [URL](#) *baseURL*:

1. Let *parsed* be the result of [parsing a JSON string to an Infra value](#) given *input*.
2. If *parsed* is not an [ordered map](#), then throw a [TypeError](#) indicating that the top-level value needs to be a JSON object.
3. Let *sortedAndNormalizedImports* be an empty [ordered map](#).
4. If *parsed*["imports"] [exists](#), then:
  1. If *parsed*["imports"] is not an [ordered map](#), then throw a [TypeError](#) indicating that the value for the "imports"

top-level key needs to be a JSON object.

2. Set `sortedAndNormalizedImports` to the result of [sorting and normalizing a module specifier map](#)<sup>p1112</sup> given `parsed["imports"]` and `baseURL`.
5. Let `sortedAndNormalizedScopes` be an empty [ordered map](#).
6. If `parsed["scopes"]` [exists](#), then:
  1. If `parsed["scopes"]` is not an [ordered map](#), then throw a `TypeError` indicating that the value for the "scopes" top-level key needs to be a JSON object.
  2. Set `sortedAndNormalizedScopes` to the result of [sorting and normalizing scopes](#)<sup>p1113</sup> given `parsed["scopes"]` and `baseURL`.
7. Let `normalizedIntegrity` be an empty [ordered map](#).
8. If `parsed["integrity"]` [exists](#), then:
  1. If `parsed["integrity"]` is not an [ordered map](#), then throw a `TypeError` indicating that the value for the "integrity" top-level key needs to be a JSON object.
  2. Set `normalizedIntegrity` to the result of [normalizing a module integrity map](#)<sup>p1113</sup> given `parsed["integrity"]` and `baseURL`.
9. If `parsed`'s [keys contains](#) any items besides "imports", "scopes", or "integrity", then the user agent should [report a warning to the console](#) indicating that an invalid top-level key was present in the import map.

#### Note

*This can help detect typos. It is not an error, because that would prevent any future extensions from being added backward-compatibly.*

10. Return an [import map](#)<sup>p1107</sup> whose [imports](#)<sup>p1107</sup> are `sortedAndNormalizedImports`, whose [scopes](#)<sup>p1107</sup> are `sortedAndNormalizedScopes`, and whose [integrity](#)<sup>p1107</sup> are `normalizedIntegrity`.

#### Example

The [import map](#)<sup>p1107</sup> that results from this parsing algorithm is highly normalized. For example, given a base URL of `https://example.com/base/page.html`, the input

```
{
  "imports": {
    "/app/helper": "node_modules/helper/index.mjs",
    "lodash": "/node_modules/lodash-es/lodash.js"
  }
}
```

will generate an [import map](#)<sup>p1107</sup> with [imports](#)<sup>p1107</sup> of

```
« [
  "https://example.com/app/helper" → https://example.com/base/node_modules/helper/index.mjs
  "lodash" → https://example.com/node_modules/lodash-es/lodash.js
] »
```

and (despite nothing being present in the input string) an empty [ordered map](#) for its [scopes](#)<sup>p1107</sup>.

To **merge module specifier maps**, given a [module specifier map](#)<sup>p1107</sup> `newMap` and a [module specifier map](#)<sup>p1107</sup> `oldMap`:

1. Let `mergedMap` be a deep copy of `oldMap`.
2. [For each](#) `specifier`  $\rightarrow$  `url` of `newMap`:
  1. If `specifier` [exists](#) in `oldMap`, then:
    1. The user agent may [report a warning to the console](#) indicating the ignored rule. They may choose to

avoid reporting if the rule is identical to an existing one.

2. [Continue](#).

2. Set `mergedMap[specifier]` to `url`.

3. Return `mergedMap`.

To **merge existing and new import maps**, given a [global object](#)<sup>p1077</sup> `global` and an [import map](#)<sup>p1107</sup> `newImportMap`:

1. Let `newImportMapScopes` be a deep copy of `newImportMap`'s [scopes](#)<sup>p1107</sup>.

**Note**

*We're mutating these copies and removing items from them when they are used to ignore scope-specific rules. This is true for `newImportMapScopes`, as well as to `newImportMapImports` below.*

2. Let `oldImportMap` be `global`'s [import map](#)<sup>p1077</sup>.

3. Let `newImportMapImports` be a deep copy of `newImportMap`'s [imports](#)<sup>p1107</sup>.

4. [For each](#) `scopePrefix` → `scopeImports` of `newImportMapScopes`:

1. [For each](#) record of `global`'s [resolved module set](#)<sup>p1077</sup>:

1. If `scopePrefix` is record's [serialized base URL](#)<sup>p1107</sup>, or if `scopePrefix` ends with U+002F (/) and `scopePrefix` is a [code unit prefix](#) of record's [serialized base URL](#)<sup>p1107</sup>, then:

1. [For each](#) `specifierKey` → `resolutionResult` of `scopeImports`:

1. If `specifierKey` is record's [specifier](#)<sup>p1107</sup>, or if all of the following conditions are true:

- `specifierKey` ends with U+002F (/);
- `specifierKey` is a [code unit prefix](#) of record's [specifier](#)<sup>p1107</sup>;
- either record's [specifier as a URL](#)<sup>p1107</sup> is null or [is special](#),

then:

1. The user agent may [report a warning to the console](#) indicating the ignored rule. They may choose to avoid reporting if the rule is identical to an existing one.
2. Remove `scopeImports[specifierKey]`.

**Note**

*Implementers are encouraged to implement a more efficient matching algorithm when working with the [resolved module set](#)<sup>p1077</sup>. As guidance, the number of resolved/mapped modules in a large application can be on the order of thousands.*

2. If `scopePrefix` [exists](#) in `oldImportMap`'s [scopes](#)<sup>p1107</sup>, then set `oldImportMap`'s [scopes](#)<sup>p1107</sup>[`scopePrefix`] to the result of [merging module specifier maps](#)<sup>p1108</sup>, given `scopeImports` and `oldImportMap`'s [scopes](#)<sup>p1107</sup>[`scopePrefix`].

3. Otherwise, set `oldImportMap`'s [scopes](#)<sup>p1107</sup>[`scopePrefix`] to `scopeImports`.

5. [For each](#) `url` → `integrity` of `newImportMap`'s [integrity](#)<sup>p1107</sup>:

1. If `url` [exists](#) in `oldImportMap`'s [integrity](#)<sup>p1107</sup>, then:

1. The user agent may [report a warning to the console](#) indicating the ignored rule. They may choose to avoid reporting if the rule is identical to an existing one.

2. [Continue](#).

2. Set `oldImportMap`'s [integrity](#)<sup>p1107</sup>[`url`] to `integrity`.

6. [For each](#) record of `global`'s [resolved module set](#)<sup>p1077</sup>:

1. [For each](#) `specifier` → `url` of `newImportMapImports`:

1. If *specifier* [starts with](#) *record's specifier*<sup>p1107</sup>, then:

1. The user agent may [report a warning to the console](#) indicating the ignored rule. They may choose to avoid reporting if the rule is identical to an existing one.
2. Remove *newImportMapImports*[*specifier*].

7. Set *oldImportMap*'s *imports*<sup>p1107</sup> to the result of [merge module specifier maps](#)<sup>p1108</sup>, given *newImportMapImports* and *oldImportMap*'s *imports*<sup>p1107</sup>.

The above algorithm merges a new import map into the given [environment settings object](#)<sup>p1076</sup>'s [global object](#)<sup>p1076</sup>'s [import map](#)<sup>p1107</sup>. Let's examine a few examples:

#### Example

There are two cases when rules of the new import map don't get merged into the existing one.

1. The new import map rule has the exact same scope and specifier as a rule in the existing import map. We'll call that "conflicting rule".
2. The new import map rule may impact the resolution of an already resolved module. We'll call that "impacted already resolved module".

When the new import map has no conflicting rules, and there are no impacted resolved modules, the resulting map would be a combination of the new and existing maps. Rules that would have individually impacted similar modules (e.g. `"/app/"` and `"/app/helper"`) but are not an exact match are not conflicting, and all make it to the merged map.

So, the following existing and new import maps:

```
{
  "imports": {
    "/app/": "./original-app/",
  }
}
```

```
{
  "imports": {
    "/app/helper": "./helper/index.mjs"
  },
  "scopes": {
    "/js": {
      "/app/": "./js-app/"
    }
  }
}
```

Would be equivalent to the following single import map:

```
{
  "imports": {
    "/app/": "./original-app/",
    "/app/helper": "./helper/index.mjs"
  },
  "scopes": {
    "/js": {
      "/app/": "./js-app/"
    }
  }
}
```

#### Example

When the new import map impacts an already resolved module, that rule gets dropped from the import map.

So, if the [resolved module set](#)<sup>p1077</sup> already contains the `"/app/helper"`, the following new import map:

```
{
  "imports": {
    "/app/helper": "./helper/index.mjs",
    "lodash": "/node_modules/lodash-es/lodash.js"
  }
}
```

Would be equivalent to the following one:

```
{
  "imports": {
    "lodash": "/node_modules/lodash-es/lodash.js"
  }
}
```

#### Example

The same is true for rules that impact already resolved modules defined in specific scopes. If we already resolved `"/app/helper"` from `"/app/main.mjs"` the following new import map:

```
{
  "scopes": {
    "/app/": {
      "/app/helper": "./helper/index.mjs"
    }
  },
  "imports": {
    "lodash": "/node_modules/lodash-es/lodash.js"
  }
}
```

Would similarly be equivalent to:

```
{
  "imports": {
    "lodash": "/node_modules/lodash-es/lodash.js"
  }
}
```

#### Example

We could also have cases where a single already-resolved module specifier has multiple rules for its resolution, depending on the referring script. In such cases, only the relevant rules would not be added to the map.

For example, if we already resolved `"/app/helper"` from `"/app/vendor/main.mjs"`, the following new import map:

```
{
  "scopes": {
    "/app/": {
      "/app/helper": "./helper/index.mjs"
    },
    "/app/vendor/": {
      "/app/": "./vendor_helper/"
    },
    "/vendor/": {
      "/app/helper": "./helper/vendor_index.mjs"
    }
  }
}
```

```

    }
  },
  "imports": {
    "lodash": "/node_modules/lodash-es/lodash.js"
    "/app/": "./general_app_path/"
    "/app/helper": "./other_path/helper/index.mjs"
  }
}

```

Would be equivalent to:

```

{
  "scopes": {
    "/vendor/": {
      "/app/helper": "./helper/vendor_index.mjs"
    }
  },
  "imports": {
    "lodash": "/node_modules/lodash-es/lodash.js"
  }
}

```

This is achieved by the fact that the merge algorithm tracks already resolved modules and removes rules affecting them from new import maps before they are merged into the existing one.

### Example

When the new import map has conflicting rules to the existing import map, with no impacted already resolved modules, the existing import map rules persist.

For example, the following existing and new import maps:

```

{
  "imports": {
    "/app/helper": "./helper/index.mjs",
    "lodash": "/node_modules/lodash-es/lodash.js"
  }
}

```

```

{
  "imports": {
    "/app/helper": "./main/helper/index.mjs"
  }
}

```

Would be equivalent to the following single import map:

```

{
  "imports": {
    "/app/helper": "./helper/index.mjs",
    "lodash": "/node_modules/lodash-es/lodash.js",
  }
}

```

To **sort and normalize a module specifier map**, given an [ordered map](#) *originalMap* and a [URL](#) *baseUrl*:

1. Let *normalized* be an empty [ordered map](#).
2. [For each](#) *specifierKey*  $\rightarrow$  *value* of *originalMap*:

1. Let *normalizedSpecifierKey* be the result of [normalizing a specifier key](#)<sup>p1114</sup> given *specifierKey* and *baseURL*.
2. If *normalizedSpecifierKey* is null, then [continue](#).
3. If *value* is not a [string](#), then:
  1. The user agent may [report a warning to the console](#) indicating that addresses need to be strings.
  2. Set *normalized[normalizedSpecifierKey]* to null.
  3. [Continue](#).
4. Let *addressURL* be the result of [resolving a URL-like module specifier](#)<sup>p1103</sup> given *value* and *baseURL*.
5. If *addressURL* is null, then:
  1. The user agent may [report a warning to the console](#) indicating that the address was invalid.
  2. Set *normalized[normalizedSpecifierKey]* to null.
  3. [Continue](#).
6. If *specifierKey* ends with U+002F (/), and the [serialization](#) of *addressURL* does not end with U+002F (/), then:
  1. The user agent may [report a warning to the console](#) indicating that an invalid address was given for the specifier key *specifierKey*; since *specifierKey* ends with a slash, the address needs to as well.
  2. Set *normalized[normalizedSpecifierKey]* to null.
  3. [Continue](#).
7. Set *normalized[normalizedSpecifierKey]* to *addressURL*.
3. Return the result of [sorting in descending order](#) *normalized*, with an entry *a* being less than an entry *b* if *a*'s [key](#) is [code unit less than](#) *b*'s [key](#).

To **sort and normalize scopes**, given an [ordered map](#) *originalMap* and a [URL](#) *baseURL*:

1. Let *normalized* be an empty [ordered map](#).
2. [For each](#) *scopePrefix* → *potentialSpecifierMap* of *originalMap*:
  1. If *potentialSpecifierMap* is not an [ordered map](#), then throw a [TypeError](#) indicating that the value of the scope with prefix *scopePrefix* needs to be a JSON object.
  2. Let *scopePrefixURL* be the result of [URL parsing](#) *scopePrefix* with *baseURL*.
  3. If *scopePrefixURL* is failure, then:
    1. The user agent may [report a warning to the console](#) that the scope prefix URL was not parseable.
    2. [Continue](#).
  4. Let *normalizedScopePrefix* be the [serialization](#) of *scopePrefixURL*.
  5. Set *normalized[normalizedScopePrefix]* to the result of [sorting and normalizing a module specifier map](#)<sup>p1112</sup> given *potentialSpecifierMap* and *baseURL*.
3. Return the result of [sorting in descending order](#) *normalized*, with an entry *a* being less than an entry *b* if *a*'s [key](#) is [code unit less than](#) *b*'s [key](#).

#### Note

In the above two algorithms, sorting keys and scopes in descending order has the effect of putting "foo/bar/" before "foo/". This in turn gives "foo/bar/" a higher priority than "foo/" during [module specifier resolution](#)<sup>p1102</sup>.

To **normalize a module integrity map**, given an [ordered map](#) *originalMap*:

1. Let *normalized* be an empty [ordered map](#).
2. [For each](#) *key* → *value* of *originalMap*:

1. Let *resolvedURL* be the result of [resolving a URL-like module specifier](#)<sup>p1103</sup> given *key* and *baseURL*.

**Note**

Unlike "imports", keys of the integrity map are treated as URLs, not module specifiers. However, we use the [resolve a URL-like module specifier](#)<sup>p1103</sup> algorithm to prohibit "bare" relative URLs like `foo`, which could be mistaken for module specifiers.

2. If *resolvedURL* is null, then:
    1. The user agent may [report a warning to the console](#) indicating that the key failed to resolve.
    2. [Continue](#).
  3. If *value* is not a [string](#), then:
    1. The user agent may [report a warning to the console](#) indicating that [integrity metadata](#) values need to be [strings](#).
    2. [Continue](#).
  4. Set *normalized[resolvedURL]* to *value*.
3. Return *normalized*.

To **normalize a specifier key**, given a [string](#) *specifierKey* and a [URL](#) *baseURL*:

1. If *specifierKey* is the empty string, then:
  1. The user agent may [report a warning to the console](#) indicating that specifier keys may not be the empty string.
  2. Return null.
2. Let *url* be the result of [resolving a URL-like module specifier](#)<sup>p1103</sup>, given *specifierKey* and *baseURL*.
3. If *url* is not null, then return the [serialization](#) of *url*.
4. Return *specifierKey*.

## 8.1.6 JavaScript specification host hooks <sup>§p11</sup><sub>14</sub>

The JavaScript specification contains a number of [implementation-defined](#) abstract operations, that vary depending on the host environment. This section defines them for user agent hosts.

### 8.1.6.1 HostEnsureCanAddPrivateElement(O) <sup>§p11</sup><sub>14</sub>

JavaScript contains an [implementation-defined](#) [HostEnsureCanAddPrivateElement\(O\)](#) abstract operation. User agents must use the following implementation: [\[JAVASCRIPT\]](#)<sup>p1479</sup>

1. If *O* is a [WindowProxy](#)<sup>p934</sup> object, or [implements](#) [Location](#)<sup>p937</sup>, then return Completion { *[[Type]]*: throw, *[[Value]]*: a new [TypeError](#) }.
2. Return [NormalCompletion](#)(unused).

**Note**

JavaScript private fields can be applied to arbitrary objects. Since this can dramatically complicate implementation for particularly-exotic host objects, the JavaScript language specification provides this hook to allow hosts to reject private fields on objects meeting a host-defined criteria. In the case of HTML, [WindowProxy](#)<sup>p934</sup> and [Location](#)<sup>p937</sup> have complicated semantics — particularly around navigation and security — that make implementation of private field semantics challenging, so our implementation simply rejects those objects.

#### 8.1.6.2 HostEnsureCanCompileStrings(*realm*, *parameterStrings*, *bodyString*, *codeString*, *compilationType*, *parameterArgs*, *bodyArg*) <sup>§ p11</sup><sub>15</sub>

JavaScript contains an [implementation-defined HostEnsureCanCompileStrings](#) abstract operation, redefined by the *Dynamic Code Brand Checks* proposal. User agents must use the following implementation: [\[JAVASCRIPT\]<sup>p1479</sup>](#) [\[JSDYNAMICCODEBRANDCHECKS\]<sup>p1479</sup>](#)

1. Perform ? [EnsureCSPDoesNotBlockStringCompilation](#)(*realm*, *parameterStrings*, *bodyString*, *codeString*, *compilationType*, *parameterArgs*, *bodyArg*). [\[CSP\]<sup>p1476</sup>](#)

#### 8.1.6.3 HostGetCodeForEval(*argument*) <sup>§ p11</sup><sub>15</sub>

The *Dynamic Code Brand Checks* proposal contains an [implementation-defined HostGetCodeForEval](#)(*argument*) abstract operation. User agents must use the following implementation: [\[JSDYNAMICCODEBRANDCHECKS\]<sup>p1479</sup>](#)

1. If *argument* is a [TrustedScript](#) object, then return *argument*'s [data](#).
2. Otherwise, return no-code.

#### 8.1.6.4 HostPromiseRejectionTracker(*promise*, *operation*) <sup>§ p11</sup><sub>15</sub>

JavaScript contains an [implementation-defined HostPromiseRejectionTracker](#)(*promise*, *operation*) abstract operation. User agents must use the following implementation: [\[JAVASCRIPT\]<sup>p1479</sup>](#)

1. Let *script* be the [running script<sup>p1097</sup>](#).
2. If *script* is a [classic script<sup>p1085</sup>](#) and *script*'s [muted errors<sup>p1085</sup>](#) is true, then return.
3. Let *settingsObject* be the [current settings object<sup>p1083</sup>](#).
4. If *script* is not null, then set *settingsObject* to *script*'s [settings object<sup>p1084</sup>](#).
5. Let *global* be *settingsObject*'s [global object<sup>p1077</sup>](#).
6. If *operation* is "reject", then:
  1. [Append](#) *promise* to *global*'s [about-to-be-notified rejected promises list<sup>p1077</sup>](#).
7. If *operation* is "handle", then:
  1. If *global*'s [about-to-be-notified rejected promises list<sup>p1077</sup>](#) contains *promise*, then [remove](#) *promise* from that list and return.
  2. If *global*'s [outstanding rejected promises weak set<sup>p1077</sup>](#) does not [contain](#) *promise*, then return.
  3. [Remove](#) *promise* from *global*'s [outstanding rejected promises weak set<sup>p1077</sup>](#).
  4. [Queue a global task<sup>p1125</sup>](#) on the [DOM manipulation task source<sup>p1134</sup>](#) given *global* to [fire an event](#) named [rejectionhandled<sup>p1472</sup>](#) at *global*, using [PromiseRejectionEvent<sup>p1100</sup>](#), with the [promise<sup>p1101</sup>](#) attribute initialized to *promise*, and the [reason<sup>p1101</sup>](#) attribute initialized to *promise*.[[PromiseResult]].

#### 8.1.6.5 HostSystemUTCEpochNanoseconds(*global*) <sup>§ p11</sup><sub>15</sub>

The Temporal proposal contains an [implementation-defined HostSystemUTCEpochNanoseconds](#) abstract operation. User agents must use the following implementation: [\[JSTEMPORAL\]<sup>p1479</sup>](#)

1. Let *settingsObject* be *global*'s [relevant settings object<sup>p1083</sup>](#).
2. Let *time* be *settingsObject*'s [current wall time](#).
3. Let *ns* be the number of nanoseconds from the [Unix epoch](#) to *time*, rounded to the nearest integer.
4. Return the result of [clamping](#) *ns* between [nsMinInstant](#) and [nsMaxInstant](#).

### 8.1.6.6 Job-related host hooks <sup>§ p11</sup><sub>16</sub>

The JavaScript specification defines Jobs to be scheduled and run later by the host, as well as [JobCallback Records](#) which encapsulate JavaScript functions that are called as part of jobs. The JavaScript specification contains a number of [implementation-defined](#) abstract operations that lets the host define how jobs are scheduled and how JobCallbacks are handled. HTML uses these abstract operations to track the [incumbent settings object](#)<sup>p1081</sup> in promises and [FinalizationRegistry](#) callbacks by saving and restoring the [incumbent settings object](#)<sup>p1081</sup> and a [JavaScript execution context](#) for the [active script](#)<sup>p1085</sup> in JobCallbacks. This section defines them for user agent hosts.

#### 8.1.6.6.1 HostCallJobCallback(callback, V, argumentsList) <sup>§ p11</sup><sub>16</sub>

JavaScript contains an [implementation-defined](#) [HostCallJobCallback](#)(callback, V, argumentsList) abstract operation to let hosts restore state when invoking JavaScript callbacks from inside tasks. User agents must use the following implementation: [\[JAVASCRIPT\]](#)<sup>p1479</sup>

1. Let *incumbent settings* be [callback](#).[[HostDefined]].[[IncumbentSettings]].
2. Let *script execution context* be [callback](#).[[HostDefined]].[[ActiveScriptContext]].
3. [Prepare to run a callback](#)<sup>p1080</sup> with *incumbent settings*.

#### Note

*This affects the [incumbent](#)<sup>p1078</sup> concept while the callback runs.*

4. If *script execution context* is not null, then [push](#) *script execution context* onto the [JavaScript execution context stack](#).

#### Note

*This affects the [active script](#)<sup>p1085</sup> while the callback runs.*

5. Let *result* be [Call](#)([callback](#).[[Callback]], V, argumentsList).
6. If *script execution context* is not null, then [pop](#) *script execution context* from the [JavaScript execution context stack](#).
7. [Clean up after running a callback](#)<sup>p1080</sup> with *incumbent settings*.
8. Return *result*.

#### 8.1.6.6.2 HostEnqueueFinalizationRegistryCleanupJob(finalizationRegistry) <sup>§ p11</sup><sub>16</sub>

JavaScript has the ability to register objects with [FinalizationRegistry](#) objects, in order to schedule a cleanup action if they are found to be garbage collected. The JavaScript specification contains an [implementation-defined](#) [HostEnqueueFinalizationRegistryCleanupJob](#)(finalizationRegistry) abstract operation to schedule the cleanup action.

#### Note

*The timing and occurrence of cleanup work is [implementation-defined](#) in the JavaScript specification. User agents might differ in when and whether an object is garbage collected, affecting both whether the return value of the [WeakRef.prototype.deref\(\)](#) method is undefined, and whether [FinalizationRegistry](#) cleanup callbacks occur. There are well-known cases in popular web browsers where objects are not accessible to JavaScript, but they remain retained by the garbage collector indefinitely. HTML clears kept-alive [WeakRef](#) objects in the [perform a microtask checkpoint](#)<sup>p1131</sup> algorithm. Authors would be best off not depending on the timing details of garbage collection implementations.*

Cleanup actions do not take place interspersed with synchronous JavaScript execution, but rather happen in queued [tasks](#)<sup>p1124</sup>. User agents must use the following implementation: [\[JAVASCRIPT\]](#)<sup>p1479</sup>

1. Let *global* be [finalizationRegistry](#).[[Realm]]'s [global object](#)<sup>p1076</sup>.
2. [Queue a global task](#)<sup>p1125</sup> on the **JavaScript engine task source** given *global* to perform the following steps:
  1. Let *entry* be [finalizationRegistry](#).[[CleanupCallback]].[[Callback]].[[Realm]]'s [environment settings object](#)<sup>p1077</sup>.
  2. [Check if we can run script](#)<sup>p1097</sup> with *entry*. If this returns "do not run", then return.

3. [Prepare to run script](#)<sup>p1097</sup> with *entry*.

**Note**

*This affects the [entry](#)<sup>p1078</sup> concept while the cleanup callback runs.*

4. Let *result* be the result of performing [CleanupFinalizationRegistry](#)(*finalizationRegistry*).
5. [Clean up after running script](#)<sup>p1097</sup> with *entry*.
6. If *result* is an [abrupt completion](#), then [report an exception](#)<sup>p1098</sup> given by *result*.[[Value]] for *global*.

#### 8.1.6.6.3 [HostEnqueueGenericJob](#)(*job*, *realm*) <sup>p11</sup><sub>17</sub>

JavaScript contains an [implementation-defined](#) [HostEnqueueGenericJob](#)(*job*, *realm*) abstract operation to perform generic jobs in a particular realm (e.g., resolve promises resulting from [Atoms.waitAsync](#)). User agents must use the following implementation: [\[JAVASCRIPT\]](#)<sup>p1479</sup>

1. Let *global* be *realm*'s [global object](#)<sup>p1077</sup>.
2. [Queue a global task](#)<sup>p1125</sup> on the [JavaScript engine task source](#)<sup>p1116</sup> given *global* to perform *job*().

#### 8.1.6.6.4 [HostEnqueuePromiseJob](#)(*job*, *realm*) <sup>p11</sup><sub>17</sub>

JavaScript contains an [implementation-defined](#) [HostEnqueuePromiseJob](#)(*job*, *realm*) abstract operation to schedule Promise-related operations. HTML schedules these operations in the microtask queue. User agents must use the following implementation: [\[JAVASCRIPT\]](#)<sup>p1479</sup>

1. If *realm* is not null, then let *job settings* be the [settings object](#)<sup>p1077</sup> for *realm*. Otherwise, let *job settings* be null.

**Note**

*If *realm* is not null, it is the [realm](#) of the author code that will run. When *job* is returned by [NewPromiseReactionJob](#), it is the realm of the promise's handler function. When *job* is returned by [NewPromiseResolveThenableJob](#), it is the realm of the *then* function.*

*If *realm* is null, either no author code will run or author code is guaranteed to throw. For the former, the author may not have passed in code to run, such as in `promise.then(null, null)`. For the latter, it is because a revoked Proxy was passed. In both cases, all the steps below that would otherwise use *job settings* get skipped.*

*[NewPromiseResolveThenableJob](#) and [NewPromiseReactionJob](#) both seem to provide non-null realms (the current Realm Record) in the case of a revoked proxy. The previous text could be updated to reflect that.*

2. [Queue a microtask](#)<sup>p1125</sup> to perform the following steps:
  1. If *job settings* is not null, then [check if we can run script](#)<sup>p1097</sup> with *job settings*. If this returns "do not run" then return.
  2. If *job settings* is not null, then [prepare to run script](#)<sup>p1097</sup> with *job settings*.

**Note**

*This affects the [entry](#)<sup>p1078</sup> concept while the job runs.*

3. Let *result* be *job*().

**Note**

**job* is an [abstract closure](#) returned by [NewPromiseReactionJob](#) or [NewPromiseResolveThenableJob](#). The promise's handler function when *job* is returned by [NewPromiseReactionJob](#), and the *then* function when *job* is returned by [NewPromiseResolveThenableJob](#), are wrapped in [JobCallback Records](#). HTML saves the [incumbent settings object](#)<sup>p1081</sup> and a [JavaScript execution context](#) for to the [active script](#)<sup>p1085</sup> in [HostMakeJobCallback](#)<sup>p1118</sup> and restores them in [HostCallJobCallback](#)<sup>p1116</sup>.*

4. If *job settings* is not null, then [clean up after running script](#)<sup>p1097</sup> with *job settings*.
5. If *result* is an [abrupt completion](#), then [report an exception](#)<sup>p1098</sup> given by *result*.[[Value]] for *realm*'s [global object](#)<sup>p1077</sup>.

There is a very gnarly case where `HostEnqueuePromiseJob` is called with a null *realm* (e.g., because `Promise.prototype.then` was called with null handlers) but also the job returns abruptly (because the promise capability's resolve or reject handler threw, possibly because this is a subclass of `Promise` that takes the supplied functions and wraps them in throwing functions before passing them on to the function passed to the `Promise` superclass constructor. Which global is to be used then, considering that the current *realm* could be different at each of those steps, by using a `Promise` constructor or `Promise.prototype.then` from another *realm*? See [issue #10526](#).

#### 8.1.6.6.5 *HostEnqueueTimeoutJob*(*job*, *realm*, *milliseconds*) §<sup>p111</sup><sub>18</sub>

JavaScript contains an [implementation-defined](#) *HostEnqueueTimeoutJob*(*job*, *milliseconds*) abstract operation to schedule an operation to be performed after a timeout. HTML schedules these operations using [run steps after a timeout](#)<sup>p1164</sup>. User agents must use the following implementation: [\[JAVASCRIPT\]](#)<sup>p1479</sup>

1. Let *global* be *realm*'s [global object](#)<sup>p1077</sup>.
2. Let *timeoutStep* be an algorithm step which [queues a global task](#)<sup>p1125</sup> on the [JavaScript engine task source](#)<sup>p1116</sup> given *global* to perform *job*().
3. [Run steps after a timeout](#)<sup>p1164</sup> given *global*, "JavaScript", *milliseconds*, and *timeoutStep*.

#### 8.1.6.6.6 *HostMakeJobCallback*(*callable*) §<sup>p111</sup><sub>18</sub>

JavaScript contains an [implementation-defined](#) *HostMakeJobCallback*(*callable*) abstract operation to let hosts attach state to JavaScript callbacks that are called from inside [task](#)<sup>p1124</sup>s. User agents must use the following implementation: [\[JAVASCRIPT\]](#)<sup>p1479</sup>

1. Let *incumbent settings* be the [incumbent settings object](#)<sup>p1081</sup>.
2. Let *active script* be the [active script](#)<sup>p1085</sup>.
3. Let *script execution context* be null.
4. If *active script* is not null, set *script execution context* to a new [JavaScript execution context](#), with its `Function` field set to null, its `Realm` field set to *active script*'s [settings object](#)<sup>p1084</sup>'s [realm](#)<sup>p1077</sup>, and its `ScriptOrModule` set to *active script*'s [record](#)<sup>p1084</sup>.

#### Note

As seen below, this is used in order to propagate the current [active script](#)<sup>p1085</sup> forward to the time when the job callback is invoked.

#### Example

A case where *active script* is non-null, and saving it in this way is useful, is the following:

```
Promise.resolve('import(`./example.mjs`)').then(eval);
```

Without this step (and the steps that use it in [HostCallJobCallback](#)<sup>p1116</sup>), there would be no [active script](#)<sup>p1085</sup> when the `import()` expression is evaluated, since `eval()` is a built-in function that does not originate from any particular [script](#)<sup>p1084</sup>.

With this step in place, the active script is propagated from the above code into the job, allowing `import()` to use the original script's [base URL](#)<sup>p1085</sup> appropriately.

#### Example

*active script* can be null if the user clicks on the following button:

```
<button onclick="Promise.resolve('import(`./example.mjs`)').then(eval)">Click me</button>
```

In this case, the JavaScript function for the [event handler](#)<sup>p1136</sup> will be created by the [get the current value of the event handler](#)<sup>p1142</sup> algorithm, which creates a function with null [\[\[ScriptOrModule\]\]](#) value. Thus, when the promise machinery calls [HostMakeJobCallback](#)<sup>p1118</sup>, there will be no [active script](#)<sup>p1085</sup> to pass along.

As a consequence, this means that when the `import()` expression is evaluated, there will still be no [active script](#)<sup>p1085</sup>. Fortunately that is handled by our implementation of [HostLoadImportedModule](#)<sup>p1121</sup> by falling back to using the [current settings object](#)<sup>p1083</sup>'s [API base URL](#)<sup>p1076</sup>.

- Return the [JobCallback Record](#) { [\[\[Callback\]\]](#): *callable*, [\[\[HostDefined\]\]](#): { [\[\[IncumbentSettings\]\]](#): *incumbent settings*, [\[\[ActiveScriptContext\]\]](#): *script execution context* } }.

### 8.1.6.7 Module-related host hooks <sup>§<sup>p11</sup><sub>19</sub></sup>

The JavaScript specification defines a syntax for modules, as well as some host-agnostic parts of their processing model. This specification defines the rest of their processing model: how the module system is bootstrapped, via the [script](#)<sup>p652</sup> element with [type](#)<sup>p653</sup> attribute set to "module", and how modules are fetched, resolved, and executed. [\[JAVASCRIPT\]](#)<sup>p1479</sup>

#### Note

Although the JavaScript specification speaks in terms of "scripts" versus "modules", in general this specification speaks in terms of [classic scripts](#)<sup>p1085</sup> versus [module scripts](#)<sup>p1085</sup>, since both of them use the [script](#)<sup>p652</sup> element.

For web developers (non-normative)

**`modulePromise = import(specifier)`**

Returns a promise for the module namespace object for the [module script](#)<sup>p1085</sup> identified by *specifier*. This allows dynamic importing of module scripts at runtime, instead of statically using the `import` statement form. The specifier will be [resolved](#)<sup>p1102</sup> relative to the [active script](#)<sup>p1085</sup>.

The returned promise will be rejected if an invalid specifier is given, or if a failure is encountered while [fetching](#)<sup>p1121</sup> or evaluating the resulting module graph.

This syntax can be used inside both [classic](#)<sup>p1085</sup> and [module scripts](#)<sup>p1085</sup>. It thus provides a bridge into the module-script world, from the classic-script world.

**`url = import.meta.url`**<sup>p1121</sup>

Returns the [active module script](#)<sup>p1085</sup>'s [base URL](#)<sup>p1085</sup>.

This syntax can only be used inside [module scripts](#)<sup>p1085</sup>.

**`url = import.meta.resolve(specifier)`**<sup>p1121</sup>

Returns *specifier*, [resolved](#)<sup>p1102</sup> relative to the [active script](#)<sup>p1085</sup>. That is, this returns the URL that would be imported by using `import(specifier)`.

Throws a `TypeError` exception if an invalid specifier is given.

This syntax can only be used inside [module scripts](#)<sup>p1085</sup>.

A **module map** is a [map](#) keyed by [tuples](#) consisting of a [URL record](#) and a [string](#). The [URL record](#) is the [request URL](#) at which the module was fetched, and the [string](#) indicates the type of the module (e.g. "javascript-or-wasm"). The [module map](#)<sup>p1119</sup>'s values are either a [module script](#)<sup>p1085</sup>, null (used to represent failed fetches), or a placeholder value "fetching". [Module maps](#)<sup>p1119</sup> are used to ensure that imported module scripts are only fetched, parsed, and evaluated once per [Document](#)<sup>p130</sup> or [worker](#)<sup>p1212</sup>.

#### Example

Since [module maps](#)<sup>p1119</sup> are keyed by (URL, module type), the following code will create three separate entries in the [module map](#)<sup>p1119</sup>, since it results in three different (URL, module type) [tuples](#) (all with "javascript-or-wasm" type):

```
import "https://example.com/module.mjs";
import "https://example.com/module.mjs#map-buster";
```

```
import "https://example.com/module.mjs?debug=true";
```

That is, URL [queries](#) and [fragments](#) can be varied to create distinct entries in the [module map](#)<sup>p1119</sup>; they are not ignored. Thus, three separate fetches and three separate module evaluations will be performed.

In contrast, the following code would only create a single entry in the [module map](#)<sup>p1119</sup>, since after applying the [URL parser](#) to these inputs, the resulting [URL records](#) are equal:

```
import "https://example.com/module2.mjs";
import "https:example.com/module2.mjs";
import "https://example.com/module2.mjs";
import "https://example.com/foo/../module2.mjs";
```

So in this second example, only one fetch and one module evaluation will occur.

Note that this behavior is the same as how [shared workers](#)<sup>p1237</sup> are keyed by their parsed [constructor url](#)<sup>p1230</sup>.

#### Example

Since module type is also part of the [module map](#)<sup>p1119</sup> key, the following code will create two separate entries in the [module map](#)<sup>p1119</sup> (the type is "javascript-or-wasm" for the first, and "css" for the second):

```
<script type=module>
  import "https://example.com/module";
</script>
<script type=module>
  import "https://example.com/module" with { type: "css" };
</script>
```

This can result in two separate fetches and two separate module evaluations being performed.

In practice, due to the as-yet-unspecified memory cache (see issue [#6110](#)) the resource may only be fetched once in WebKit and Blink-based browsers. Additionally, as long as all module types are mutually exclusive, the module type check in [fetch a single module script](#)<sup>p1091</sup> will fail for at least one of the imports, so at most one module evaluation will occur.

The purpose of including the type in the [module map](#)<sup>p1119</sup> key is so that an import with the wrong type attribute does not prevent a different import of the same specifier but with the correct type from succeeding.

#### Example

JavaScript module scripts are the default import type when importing from another JavaScript module; that is, when an `import` statement lacks a `type` import attribute the imported module script's type will be JavaScript. Attempting to import a JavaScript resource using an `import` statement with a `type` import attribute will fail:

```
<script type="module">
  // All of the following will fail, assuming that the imported .mjs files are served with a
  // JavaScript MIME type. JavaScript module scripts are the default and cannot be imported with
  // any import type attribute.
  import foo from "./foo.mjs" with { type: "javascript" };
  import foo2 from "./foo2.mjs" with { type: "js" };
  import foo3 from "./foo3.mjs" with { type: "" };
  await import("./foo4.mjs", { with: { type: null } });
  await import("./foo5.mjs", { with: { type: undefined } });
</script>
```

#### 8.1.6.7.1 *HostGetImportMetaProperties(moduleRecord)* §<sup>p11</sup><sub>21</sub>

JavaScript contains an [implementation-defined HostGetImportMetaProperties](#) abstract operation. User agents must use the following implementation: [\[JAVASCRIPT\]](#)<sup>p1479</sup>

1. Let *moduleScript* be *moduleRecord*.[[HostDefined]].
2. **Assert**: *moduleScript*'s [base URL](#)<sup>p1085</sup> is not null, as *moduleScript* is a [JavaScript module script](#)<sup>p1085</sup>.
3. Let *urlString* be *moduleScript*'s [base URL](#)<sup>p1085</sup>, [serialized](#).
4. Let *steps* be the following steps, given the argument *specifier*:
  1. Set *specifier* to ? [ToString](#)(*specifier*).
  2. Let *url* be the result of [resolving a module specifier](#)<sup>p1102</sup> given *moduleScript* and *specifier*.
  3. Return the [serialization](#) of *url*.
5. Let *resolveFunction* be ! [CreateBuiltinFunction](#)(*steps*, 1, "resolve", « »).
6. Return « [Record](#) { [[Key]]: "url", [[Value]]: *urlString* }, [Record](#) { [[Key]]: "resolve", [[Value]]: *resolveFunction* } ».

#### 8.1.6.7.2 *HostGetSupportedImportAttributes()* §<sup>p11</sup><sub>21</sub>

The *Import Attributes* proposal contains an [implementation-defined HostGetSupportedImportAttributes](#) abstract operation. User agents must use the following implementation: [\[JSIMPORTATTRIBUTES\]](#)<sup>p1479</sup>

1. Return « "type" ».

#### 8.1.6.7.3 *HostLoadImportedModule(referrer, moduleRequest, loadState, payload)* §<sup>p11</sup><sub>21</sub>

JavaScript contains an [implementation-defined HostLoadImportedModule](#) abstract operation. User agents must use the following implementation: [\[JAVASCRIPT\]](#)<sup>p1479</sup>

1. Let *settingsObject* be the [current settings object](#)<sup>p1083</sup>.
2. If *settingsObject*'s [global object](#)<sup>p1077</sup> implements [WorkletGlobalScope](#)<sup>p1245</sup> or [ServiceWorkerGlobalScope](#) and *loadState* is undefined, then:

#### Note

*loadState is undefined when the current fetching process has been initiated by a dynamic [import\(\)](#) call, either directly or when loading the transitive dependencies of the dynamically imported module.*

1. Let *completion* be [Completion Record](#) { [[Type]]: throw, [[Value]]: a new [TypeError](#), [[Target]]: empty }.
2. Perform [FinishLoadingImportedModule](#)(*referrer*, *moduleRequest*, *payload*, *completion*).
3. Return.
3. Let *referencingScript* be null.
4. Let *originalFetchOptions* be the [default script fetch options](#)<sup>p1086</sup>.
5. Let *fetchReferrer* be "client".
6. If *referrer* is a [Script Record](#) or a [Cyclic Module Record](#), then:
  1. Set *referencingScript* to *referrer*.[[HostDefined]].
  2. Set *settingsObject* to *referencingScript*'s [settings object](#)<sup>p1084</sup>.
  3. Set *fetchReferrer* to *referencingScript*'s [base URL](#)<sup>p1085</sup>.
  4. Set *originalFetchOptions* to *referencingScript*'s [fetch options](#)<sup>p1085</sup>.

### Example

`referrer` is usually a [Script Record](#) or a [Cyclic Module Record](#), but it will not be so for event handlers per the [get the current value of the event handler](#)<sup>p1142</sup> algorithm. For example, given:

```
<button onclick="import('./foo.mjs')">Click me</button>
```

If a `click` event occurs, then at the time the `import()` expression runs, [GetActiveScriptOrModule](#) will return null, and this operation will receive the [current realm](#) as a fallback `referrer`.

7. If `referrer` is a [Cyclic Module Record](#) and `moduleRequest` is equal to the first element of `referrer.[RequestedModules]`, then:

1. [For each ModuleRequest record](#) requested of `referrer.[RequestedModules]`:
  1. If `moduleRequest.[Attributes]` contains a [Record](#) entry such that `entry.[Key]` is not "type", then:
    1. Let `completion` be [Completion Record](#) { `[[Type]]`: throw, `[[Value]]`: a new [SyntaxError](#) exception, `[[Target]]`: empty }.
    2. Perform [FinishLoadingImportedModule](#)(`referrer`, `moduleRequest`, `payload`, `completion`).
    3. Return.

### Note

*The JavaScript specification re-performs this validation but it is duplicated here to avoid unnecessarily loading any of the dependencies on validation failure.*

2. [Resolve a module specifier](#)<sup>p1102</sup> given `referencingScript` and `moduleRequest.[Specifier]`, catching any exceptions. If they throw an exception, let `resolutionError` be the thrown exception.
3. If the previous step threw an exception, then:
  1. Let `completion` be [Completion Record](#) { `[[Type]]`: throw, `[[Value]]`: `resolutionError`, `[[Target]]`: empty }.
  2. Perform [FinishLoadingImportedModule](#)(`referrer`, `moduleRequest`, `payload`, `completion`).
  3. Return.
4. Let `moduleType` be the result of running the [module type from module request](#)<sup>p1095</sup> steps given `moduleRequest`.
5. If the result of running the [module type allowed](#)<sup>p1095</sup> steps given `moduleType` and `settingsObject` is false, then:
  1. Let `completion` be [Completion Record](#) { `[[Type]]`: throw, `[[Value]]`: a new [TypeError](#) exception, `[[Target]]`: empty }.
  2. Perform [FinishLoadingImportedModule](#)(`referrer`, `moduleRequest`, `payload`, `completion`).
  3. Return.

### Note

*This step is essentially validating all of the requested module specifiers and type attributes when the first call to [HostLoadImportedModule](#)<sup>p1121</sup> for a static module dependency list is made, to avoid further loading operations in the case any one of the dependencies has a static error. We treat a module with unresolvable module specifiers or unsupported type attributes the same as one that cannot be parsed; in both cases, a syntactic issue makes it impossible to ever contemplate linking the module later.*

8. Let `url` be the result of [resolving a module specifier](#)<sup>p1102</sup> given `referencingScript` and `moduleRequest.[Specifier]`, catching any exceptions. If they throw an exception, let `resolutionError` be the thrown exception.
9. If the previous step threw an exception, then:
  1. Let `completion` be [Completion Record](#) { `[[Type]]`: throw, `[[Value]]`: `resolutionError`, `[[Target]]`: empty }.
  2. Perform [FinishLoadingImportedModule](#)(`referrer`, `moduleRequest`, `payload`, `completion`).
  3. Return.

10. Let *fetchOptions* be the result of [getting the descendant script fetch options](#)<sup>p1086</sup> given *originalFetchOptions*, *url*, and *settingsObject*.
11. Let *destination* be "script".
12. Let *fetchClient* be *settingsObject*.
13. If *loadState* is not undefined, then:
  1. Set *destination* to *loadState*.[[Destination]].
  2. Set *fetchClient* to *loadState*.[[FetchClient]].
14. [Fetch a single imported module script](#)<sup>p1093</sup> given *url*, *fetchClient*, *destination*, *fetchOptions*, *settingsObject*, *fetchReferrer*, *moduleRequest*, and *onSingleFetchComplete* as defined below. If *loadState* is not undefined and *loadState*.[[PerformFetch]] is not null, pass *loadState*.[[PerformFetch]] along as well.

*onSingleFetchComplete* given *moduleScript* is the following algorithm:

1. Let *completion* be null.
2. If *moduleScript* is null, then set *completion* to [Completion Record](#) { [[Type]]: throw, [[Value]]: a new [TypeError](#), [[Target]]: empty }.
3. Otherwise, if *moduleScript*'s [parse error](#)<sup>p1084</sup> is not null, then:
  1. Let *parseError* be *moduleScript*'s [parse error](#)<sup>p1084</sup>.
  2. Set *completion* to [Completion Record](#) { [[Type]]: throw, [[Value]]: *parseError*, [[Target]]: empty }.
  3. If *loadState* is not undefined and *loadState*.[[ParseError]] is null, set *loadState*.[[ParseError]] to *parseError*.
4. Otherwise, set *completion* to [Completion Record](#) { [[Type]]: normal, [[Value]]: *moduleScript*'s [record](#)<sup>p1084</sup>, [[Target]]: empty }.
5. Perform [FinishLoadingImportedModule](#)(*referrer*, *moduleRequest*, *payload*, *completion*).

## 8.1.7 Event loops <sup>§ p11</sup>

### 8.1.7.1 Definitions <sup>§ p11</sup>

To coordinate events, user interaction, scripts, rendering, networking, and so forth, user agents must use **event loops** as described in this section. Each [agent](#) has an associated **event loop**, which is unique to that agent.

The [event loop](#)<sup>p1123</sup> of a [similar-origin window agent](#)<sup>p1072</sup> is known as a **window event loop**. The [event loop](#)<sup>p1123</sup> of a [dedicated worker agent](#)<sup>p1072</sup>, [shared worker agent](#)<sup>p1072</sup>, or [service worker agent](#)<sup>p1072</sup> is known as a **worker event loop**. And the [event loop](#)<sup>p1123</sup> of a [worklet agent](#)<sup>p1072</sup> is known as a **worklet event loop**.

#### Note

[Event loops](#)<sup>p1123</sup> do not necessarily correspond to implementation threads. For example, multiple [window event loops](#)<sup>p1123</sup> could be cooperatively scheduled in a single thread.

However, for the various worker [agents](#) that are allocated with [[CanBlock]] set to true, the JavaScript specification does place requirements on them regarding [forward progress](#), which effectively amount to requiring dedicated per-agent threads in those cases.

An [event loop](#)<sup>p1123</sup> has one or more **task queues**. A [task queue](#)<sup>p1123</sup> is a [set](#) of [tasks](#)<sup>p1124</sup>.

#### Note

[Task queues](#)<sup>p1123</sup> are [sets](#), not [queues](#), because the [event loop processing model](#)<sup>p1126</sup> grabs the first [runnable](#)<sup>p1124</sup> [task](#)<sup>p1124</sup> from the chosen queue, instead of [dequeuing](#) the first task.

## Note

The [microtask queue](#)<sup>p1124</sup> is not a [task queue](#)<sup>p1123</sup>.

Tasks encapsulate algorithms that are responsible for such work as:

## Events

Dispatching an [Event](#) object at a particular [EventTarget](#) object is often done by a dedicated task.

## Note

Not all events are dispatched using the [task queue](#)<sup>p1123</sup>; many are dispatched during other tasks.

## Parsing

The [HTML parser](#)<sup>p1271</sup> tokenizing one or more bytes, and then processing any resulting tokens, is typically a task.

## Callbacks

Calling a callback is often done by a dedicated task.

## Using a resource

When an algorithm [fetches](#) a resource, if the fetching occurs in a non-blocking fashion then the processing of the resource once some or all of the resource is available is performed by a task.

## Reacting to DOM manipulation

Some elements have tasks that trigger in response to DOM manipulation, e.g. when that element is [inserted into the document](#)<sup>p46</sup>.

Formally, a **task** is a [struct](#) which has:

### Steps

A series of steps specifying the work to be done by the task.

### A source

One of the [task sources](#)<sup>p1124</sup>, used to group and serialize related tasks.

### A document

A [Document](#)<sup>p130</sup> associated with the task, or null for tasks that are not in a [window event loop](#)<sup>p1123</sup>.

### A script evaluation environment settings object set

A [set](#) of [environment settings objects](#)<sup>p1076</sup> used for tracking script evaluation during the task.

A [task](#)<sup>p1124</sup> is **runnable** if its [document](#)<sup>p1124</sup> is either null or [fully active](#)<sup>p1003</sup>.

Per its [source](#)<sup>p1124</sup> field, each [task](#)<sup>p1124</sup> is defined as coming from a specific **task source**. For each [event loop](#)<sup>p1123</sup>, every [task source](#)<sup>p1124</sup> must be associated with a specific [task queue](#)<sup>p1123</sup>.

## Note

Essentially, [task sources](#)<sup>p1124</sup> are used within standards to separate logically-different types of tasks, which a user agent might wish to distinguish between. [Task queues](#)<sup>p1123</sup> are used by user agents to coalesce task sources within a given [event loop](#)<sup>p1123</sup>.

## Example

For example, a user agent could have one [task queue](#)<sup>p1123</sup> for mouse and key events (to which the [user interaction task source](#)<sup>p1134</sup> is associated), and another to which all other [task sources](#)<sup>p1124</sup> are associated. Then, using the freedom granted in the initial step of the [event loop processing model](#)<sup>p1126</sup>, it could give keyboard and mouse events preference over other tasks three-quarters of the time, keeping the interface responsive but not starving other task queues. Note that in this setup, the processing model still enforces that the user agent would never process events from any one [task source](#)<sup>p1124</sup> out of order.

Each [event loop](#)<sup>p1123</sup> has a **currently running task**, which is either a [task](#)<sup>p1124</sup> or null. Initially, this is null. It is used to handle reentrancy.

Each [event loop](#)<sup>p1123</sup> has a **microtask queue**, which is a [queue](#) of [microtasks](#)<sup>p1124</sup>, initially empty. A **microtask** is a colloquial way of referring to a [task](#)<sup>p1124</sup> that was created via the [queue a microtask](#)<sup>p1125</sup> algorithm.

Each [event loop](#)<sup>p1123</sup> has a **performing a microtask checkpoint** boolean, which is initially false. It is used to prevent reentrant invocation of the [perform a microtask checkpoint](#)<sup>p1131</sup> algorithm.

Each [window event loop](#)<sup>p1123</sup> has a [DOMHighResTimeStamp](#) **last render opportunity time**, initially set to zero.

Each [window event loop](#)<sup>p1123</sup> has a [DOMHighResTimeStamp](#) **last idle period start time**, initially set to zero.

To get the **same-loop windows** for a [window event loop](#)<sup>p1123</sup> loop, return all [Window](#)<sup>p922</sup> objects whose [relevant agent](#)<sup>p1073</sup>'s [event loop](#)<sup>p1123</sup> is loop.

### 8.1.7.2 Queuing tasks <sup>p11</sup><sub>25</sub>

To **queue a task** on a [task source](#)<sup>p1124</sup> source, which performs a series of steps *steps*, optionally given an event loop *event loop* and a document *document*:

1. If *event loop* was not given, set *event loop* to the [implied event loop](#)<sup>p1126</sup>.
2. If *document* was not given, set *document* to the [implied document](#)<sup>p1126</sup>.
3. Let *task* be a new [task](#)<sup>p1124</sup>.
4. Set *task*'s [steps](#)<sup>p1124</sup> to *steps*.
5. Set *task*'s [source](#)<sup>p1124</sup> to *source*.
6. Set *task*'s [document](#)<sup>p1124</sup> to the *document*.
7. Set *task*'s [script evaluation environment settings object set](#)<sup>p1124</sup> to an empty [set](#).
8. Let *queue* be the [task queue](#)<sup>p1123</sup> to which *source* is associated on *event loop*.
9. [Append](#) *task* to *queue*.

#### ⚠Warning!

**Failing to pass an event loop and document to queue a task<sup>p1125</sup> means relying on the ambiguous and poorly-specified implied event loop<sup>p1126</sup> and implied document<sup>p1126</sup> concepts. Specification authors should either always pass these values, or use the wrapper algorithms queue a global task<sup>p1125</sup> or queue an element task<sup>p1125</sup> instead. Using the wrapper algorithms is recommended.**

To **queue a global task** on a [task source](#)<sup>p1124</sup> source, with a [global object](#)<sup>p1076</sup> *global* and a series of steps *steps*:

1. Let *event loop* be *global*'s [relevant agent](#)<sup>p1073</sup>'s [event loop](#)<sup>p1123</sup>.
2. Let *document* be *global*'s [associated Document](#)<sup>p923</sup>, if *global* is a [Window](#)<sup>p922</sup> object; otherwise null.
3. [Queue a task](#)<sup>p1125</sup> given *source*, *event loop*, *document*, and *steps*.

To **queue an element task** on a [task source](#)<sup>p1124</sup> source, with an element *element* and a series of steps *steps*:

1. Let *global* be *element*'s [relevant global object](#)<sup>p1083</sup>.
2. [Queue a global task](#)<sup>p1125</sup> given *source*, *global*, and *steps*.

To **queue a microtask** which performs a series of steps *steps*, optionally given a document *document*:

1. [Assert](#): there is a [surrounding agent](#). I.e., this algorithm is not called while [in parallel](#)<sup>p43</sup>.
2. Let *eventLoop* be the [surrounding agent](#)'s [event loop](#)<sup>p1123</sup>.
3. If *document* was not given, set *document* to the [implied document](#)<sup>p1126</sup>.
4. Let *microtask* be a new [task](#)<sup>p1124</sup>.
5. Set *microtask*'s [steps](#)<sup>p1124</sup> to *steps*.
6. Set *microtask*'s [source](#)<sup>p1124</sup> to the **microtask task source**.

7. Set *microtask*'s [document](#)<sup>p1124</sup> to *document*.
8. Set *microtask*'s [script evaluation environment settings object set](#)<sup>p1124</sup> to an empty [set](#).
9. [Enqueue](#) *microtask* on *eventLoop*'s [microtask queue](#)<sup>p1124</sup>.

#### Note

*It is possible for a [microtask](#)<sup>p1124</sup> to be moved to a regular [task queue](#)<sup>p1123</sup>, if, during its initial execution, it [spins the event loop](#)<sup>p1131</sup>. This is the only case in which the [source](#)<sup>p1124</sup>, [document](#)<sup>p1124</sup>, and [script evaluation environment settings object set](#)<sup>p1124</sup> of the *microtask* are consulted; they are ignored by the [perform a microtask checkpoint](#)<sup>p1131</sup> algorithm.*

The **implied event loop** when queuing a task is the one that can be deduced from the context of the calling algorithm. This is generally unambiguous, as most specification algorithms only ever involve a single [agent](#) (and thus a single [event loop](#)<sup>p1123</sup>). The exception is algorithms involving or specifying cross-agent communication (e.g., between a window and a worker); for those cases, the **implied event loop**<sup>p1126</sup> concept must not be relied upon and specifications must explicitly provide an [event loop](#)<sup>p1123</sup> when [queuing a task](#)<sup>p1125</sup>.

The **implied document** when queuing a task on an [event loop](#)<sup>p1123</sup> *event loop* is determined as follows:

1. If *event loop* is not a [window event loop](#)<sup>p1123</sup>, then return null.
2. If the task is being queued in the context of an element, then return the element's [node document](#).
3. If the task is being queued in the context of a [browsing context](#)<sup>p998</sup>, then return the browsing context's [active document](#)<sup>p998</sup>.
4. If the task is being queued by or for a [script](#)<sup>p1084</sup>, then return the script's [settings object](#)<sup>p1084</sup>'s [global object](#)<sup>p1077</sup>'s [associated Document](#)<sup>p923</sup>.
5. [Assert](#): this step is never reached, because one of the previous conditions is true. Really?

Both [implied event loop](#)<sup>p1126</sup> and [implied document](#)<sup>p1126</sup> are vaguely-defined and have a lot of action-at-a-distance. The hope is to remove these, especially [implied document](#)<sup>p1126</sup>. See [issue #4980](#).

### 8.1.7.3 Processing model <sup>p11</sup><sub>26</sub>

An [event loop](#)<sup>p1123</sup> must continually run through the following steps for as long as it exists:

1. Let *oldestTask* and *taskStartTime* be null.
2. If the [event loop](#)<sup>p1123</sup> has a [task queue](#)<sup>p1123</sup> with at least one [runnable](#)<sup>p1124</sup> [task](#)<sup>p1124</sup>, then:
  1. Let *taskQueue* be one such [task queue](#)<sup>p1123</sup>, chosen in an [implementation-defined](#) manner.

#### Note

*Remember that the [microtask queue](#)<sup>p1124</sup> is not a [task queue](#)<sup>p1123</sup>, so it will not be chosen in this step. However, a [task queue](#)<sup>p1123</sup> to which the [microtask task source](#)<sup>p1125</sup> is associated might be chosen in this step. In that case, the [task](#)<sup>p1124</sup> chosen in the next step was originally a [microtask](#)<sup>p1124</sup>, but it got moved as part of [spinning the event loop](#)<sup>p1131</sup>.*

2. Set *taskStartTime* to the [unsafe shared current time](#).
3. Set *oldestTask* to the first [runnable](#)<sup>p1124</sup> [task](#)<sup>p1124</sup> in *taskQueue*, and [remove](#) it from *taskQueue*.
4. If *oldestTask*'s [document](#)<sup>p1124</sup> is not null, then [record task start time](#) given *taskStartTime* and *oldestTask*'s [document](#)<sup>p1124</sup>.
5. Set the [event loop](#)<sup>p1123</sup>'s [currently running task](#)<sup>p1124</sup> to *oldestTask*.
6. Perform *oldestTask*'s [steps](#)<sup>p1124</sup>.
7. Set the [event loop](#)<sup>p1123</sup>'s [currently running task](#)<sup>p1124</sup> back to null.
8. [Perform a microtask checkpoint](#)<sup>p1131</sup>.
3. Let *taskEndTime* be the [unsafe shared current time](#). [\[HRT\]](#)<sup>p1478</sup>

4. If *oldestTask* is not null, then:

1. Let *top-level browsing contexts* be an empty [set](#).
2. For each [environment settings object](#)<sup>p1076</sup> *settings* of *oldestTask*'s [script evaluation environment settings object set](#)<sup>p1124</sup>:
  1. Let *global* be *settings*'s [global object](#)<sup>p1077</sup>.
  2. If *global* is not a [Window](#)<sup>p922</sup> object, then [continue](#).
  3. If *global*'s [browsing context](#)<sup>p923</sup> is null, then [continue](#).
  4. Let *tlbc* be *global*'s [browsing context](#)<sup>p923</sup>'s [top-level browsing context](#)<sup>p1001</sup>.
  5. If *tlbc* is not null, then [append](#) it to *top-level browsing contexts*.
3. [Report long tasks](#), passing in *taskStartTime*, *taskEndTime*, *top-level browsing contexts*, and *oldestTask*.
4. If *oldestTask*'s [document](#)<sup>p1124</sup> is not null, then [record task end time](#) given *taskEndTime* and *oldestTask*'s [document](#)<sup>p1124</sup>.

5. If this is a [window event loop](#)<sup>p1123</sup> that has no [runnable](#)<sup>p1124</sup> [task](#)<sup>p1124</sup> in this [event loop](#)<sup>p1123</sup>'s [task queues](#)<sup>p1123</sup>, then:

1. Set this [event loop](#)<sup>p1123</sup>'s [last idle period start time](#)<sup>p1125</sup> to the [unsafe shared current time](#).
2. Let *computeDeadline* be the following steps:
  1. Let *deadline* be this [event loop](#)<sup>p1123</sup>'s [last idle period start time](#)<sup>p1125</sup> plus 50.

**Note**

*The cap of 50ms in the future is to ensure responsiveness to new user input within the threshold of human perception.*

2. Let *hasPendingRenders* be false.
3. For each *windowInSameLoop* of the [same-loop windows](#)<sup>p1125</sup> for this [event loop](#)<sup>p1123</sup>:
  1. If *windowInSameLoop*'s [map of animation frame callbacks](#)<sup>p1187</sup> is not [empty](#), or if the user agent believes that the *windowInSameLoop* might have pending rendering updates, set *hasPendingRenders* to true.
  2. Let *timerCallbackEstimates* be the result of [getting the values](#) of *windowInSameLoop*'s [map of active timers](#)<sup>p1164</sup>.
  3. For each *timeoutDeadline* of *timerCallbackEstimates*, if *timeoutDeadline* is less than *deadline*, set *deadline* to *timeoutDeadline*.
4. If *hasPendingRenders* is true, then:
  1. Let *nextRenderDeadline* be this [event loop](#)<sup>p1123</sup>'s [last render opportunity time](#)<sup>p1125</sup> plus (1000 divided by the current refresh rate).

The refresh rate can be hardware- or implementation-specific. For a refresh rate of 60Hz, the *nextRenderDeadline* would be about 16.67ms after the [last render opportunity time](#)<sup>p1125</sup>.
  2. If *nextRenderDeadline* is less than *deadline*, then return *nextRenderDeadline*.
5. Return *deadline*.

3. For each *win* of the [same-loop windows](#)<sup>p1125</sup> for this [event loop](#)<sup>p1123</sup>, perform the [start an idle period algorithm](#) for *win* with the following step: return the result of calling *computeDeadline*, [coarsened](#) given *win*'s [relevant settings object](#)<sup>p1083</sup>'s [cross-origin isolated capability](#)<sup>p1076</sup>. [\[REQUESTIDLECALLBACK\]](#)<sup>p1481</sup>

6. If this is a [worker event loop](#)<sup>p1123</sup>, then:

1. If this [event loop](#)<sup>p1123</sup>'s [agent](#)'s single [realm](#)'s [global object](#)<sup>p1077</sup> is a [supported](#)<sup>p1187</sup> [DedicatedWorkerGlobalScope](#)<sup>p1230</sup> and the user agent believes that it would benefit from having its rendering updated at this time, then:

1. Let *now* be the [current high resolution time](#) given the [DedicatedWorkerGlobalScope](#)<sup>p1230</sup>. [\[HRT\]](#)<sup>p1478</sup>
2. [Run the animation frame callbacks](#)<sup>p1187</sup> for that [DedicatedWorkerGlobalScope](#)<sup>p1230</sup>, passing in *now* as the timestamp.
3. Update the rendering of that dedicated worker to reflect the current state.

#### Note

*Similar to the notes for [updating the rendering](#)<sup>p1128</sup> in a [window event loop](#)<sup>p1123</sup>, a user agent can determine the rate of rendering in the dedicated worker.*

2. If there are no [tasks](#)<sup>p1124</sup> in the [event loop](#)<sup>p1123</sup>'s [task queues](#)<sup>p1123</sup> and the [WorkerGlobalScope](#)<sup>p1228</sup> object's [closing](#)<sup>p1231</sup> flag is true, then destroy the [event loop](#)<sup>p1123</sup>, aborting these steps, resuming the [run a worker](#)<sup>p1232</sup> steps described in the [Web workers](#)<sup>p1212</sup> section below.

A [window event loop](#)<sup>p1123</sup> *eventLoop* must also run the following [in parallel](#)<sup>p43</sup>, as long as it exists:

1. Wait until at least one [navigable](#)<sup>p989</sup> whose [active document](#)<sup>p989</sup>'s [relevant agent](#)<sup>p1073</sup>'s [event loop](#)<sup>p1123</sup> is *eventLoop* might have a [rendering opportunity](#)<sup>p1130</sup>.
2. Set *eventLoop*'s [last render opportunity time](#)<sup>p1125</sup> to the [unsafe shared current time](#).
3. For each *navigable* that has a [rendering opportunity](#)<sup>p1130</sup>, [queue a global task](#)<sup>p1125</sup> on the [rendering task source](#)<sup>p1134</sup> given *navigable*'s [active window](#)<sup>p989</sup> to **update the rendering**:

#### Note

*This might cause redundant calls to [update the rendering](#)<sup>p1128</sup>. However, these calls would have no observable effect because there will be no rendering necessary, as per the [Unnecessary rendering step](#). Implementations can introduce further optimizations such as only queuing this task when it is not already queued. However, note that the document associated with the task might become inactive before the task is processed.*

1. Let *frameTimestamp* be *eventLoop*'s [last render opportunity time](#)<sup>p1125</sup>.
2. Let *docs* be all [fully active](#)<sup>p1003</sup> [Document](#)<sup>p130</sup> objects whose [relevant agent](#)<sup>p1073</sup>'s [event loop](#)<sup>p1123</sup> is *eventLoop*, sorted arbitrarily except that the following conditions must be met:
  - Any [Document](#)<sup>p130</sup> *B* whose [container document](#)<sup>p992</sup> is *A* must be listed after *A* in the list.
  - If there are two documents *A* and *B* that both have the same non-null [container document](#)<sup>p992</sup> *C*, then the order of *A* and *B* in the list must match the [shadow-including tree order](#) of their respective [navigable containers](#)<sup>p991</sup> in *C*'s [node tree](#).

In the steps below that iterate over *docs*, each [Document](#)<sup>p130</sup> must be processed in the order it is found in the list.

3. *Filter non-renderable documents*: Remove from *docs* any [Document](#)<sup>p130</sup> object *doc* for which any of the following are true:
  - *doc* is [render-blocked](#)<sup>p134</sup>;
  - *doc*'s [visibility state](#)<sup>p826</sup> is "hidden";
  - *doc*'s rendering is [suppressed for view transitions](#); or
  - *doc*'s [node navigable](#)<sup>p989</sup> doesn't currently have a [rendering opportunity](#)<sup>p1130</sup>.

#### Note

*We have to check for rendering opportunities here, in addition to checking that in the [in parallel](#)<sup>p43</sup> steps, as some documents that share the same [event loop](#)<sup>p1123</sup> might not have a [rendering opportunity](#)<sup>p1130</sup> at the same time.*

4. *Unnecessary rendering*: Remove from *docs* any [Document](#)<sup>p130</sup> object *doc* for which all of the following are true:
  - the user agent believes that updating the rendering of *doc*'s [node navigable](#)<sup>p989</sup> would have no visible effect; and
  - *doc*'s [map of animation frame callbacks](#)<sup>p1187</sup> is empty.

5. Remove from *docs* all [Document](#)<sup>p130</sup> objects for which the user agent believes that it's preferable to skip updating the rendering for other reasons.

**Note**

*The step labeled Filter non-renderable documents prevents the user agent from updating the rendering when it is unable to present new content to the user.*

*The step labeled Unnecessary rendering prevents the user agent from updating the rendering when there's no new content to draw.*

*This step enables the user agent to prevent the steps below from running for other reasons, for example, to ensure certain [tasks](#)<sup>p1124</sup> are executed immediately after each other, with only [microtask checkpoints](#)<sup>p1131</sup> interleaved (and without, e.g., [animation frame callbacks](#)<sup>p1187</sup> interleaved). Concretely, a user agent might wish to coalesce timer callbacks together, with no intermediate rendering updates.*

6. For each *doc* of *docs*, [reveal](#)<sup>p1053</sup> *doc*.
7. For each *doc* of *docs*, [flush autofocus candidates](#)<sup>p849</sup> for *doc* if its [node navigable](#)<sup>p989</sup> is a [top-level traversable](#)<sup>p990</sup>.
8. For each *doc* of *docs*, [run the resize steps](#) for *doc*. [\[CSSOMVIEW\]](#)<sup>p1477</sup>
9. For each *doc* of *docs*, [run the scroll steps](#) for *doc*. [\[CSSOMVIEW\]](#)<sup>p1477</sup>
10. For each *doc* of *docs*, [evaluate media queries and report changes](#) for *doc*. [\[CSSOMVIEW\]](#)<sup>p1477</sup>
11. For each *doc* of *docs*, [update animations and send events](#) for *doc*, passing in [relative high resolution time](#) given *frameTimestamp* and *doc*'s [relevant global object](#)<sup>p1083</sup> as the timestamp [\[WEBANIMATIONS\]](#)<sup>p1483</sup>
12. For each *doc* of *docs*, [run the fullscreen steps](#) for *doc*. [\[FULLSCREEN\]](#)<sup>p1478</sup>
13. For each *doc* of *docs*, if the user agent detects that the backing storage associated with a [CanvasRenderingContext2D](#)<sup>p682</sup> or an [OffscreenCanvasRenderingContext2D](#)<sup>p745</sup>, *context*, has been lost, then it must run the **context lost steps** for each such *context*:
  1. Let *canvas* be the value of *context*'s [canvas](#)<sup>p689</sup> attribute, if *context* is a [CanvasRenderingContext2D](#)<sup>p682</sup>, or the [associated OffscreenCanvas object](#)<sup>p746</sup> for *context* otherwise.
  2. Set *context*'s [context lost](#)<sup>p690</sup> to true.
  3. [Reset the rendering context to its default state](#)<sup>p690</sup> given *context*.
  4. Let *shouldRestore* be the result of [firing an event](#) named [contextlost](#)<sup>p1471</sup> at *canvas*, with the [cancelable](#) attribute initialized to true.
  5. If *shouldRestore* is false, then abort these steps.
  6. Attempt to restore *context* by creating a backing storage using *context*'s attributes and associating them with *context*. If this fails, then abort these steps.
  7. Set *context*'s [context lost](#)<sup>p690</sup> to false.
  8. [Fire an event](#) named [contextrestored](#)<sup>p1471</sup> at *canvas*.
14. For each *doc* of *docs*, [run the animation frame callbacks](#)<sup>p1187</sup> for *doc*, passing in the [relative high resolution time](#) given *frameTimestamp* and *doc*'s [relevant global object](#)<sup>p1083</sup> as the timestamp.
15. Let *unsafeStyleAndLayoutStartTime* be the [unsafe shared current time](#).
16. For each *doc* of *docs*:
  1. Let *resizeObserverDepth* be 0.
  2. While true:
    1. Recalculate styles and update layout for *doc*.
    2. Let *hadInitialVisibleContentVisibilityDetermination* be false.
    3. For each element *element* with ['auto'](#) used value of ['content-visibility'](#):

1. Let *checkForInitialDetermination* be true if *element*'s [proximity to the viewport](#) is not determined and it is not [relevant to the user](#). Otherwise, let *checkForInitialDetermination* be false.
2. Determine [proximity to the viewport](#) for *element*.
3. If *checkForInitialDetermination* is true and *element* is now [relevant to the user](#), then set *hadInitialVisibleContentVisibilityDetermination* to true.
4. If *hadInitialVisibleContentVisibilityDetermination* is true, then [continue](#).

#### Note

*The intent of this step is for the initial viewport proximity determination, which takes effect immediately, to be reflected in the style and layout calculation which is carried out in a previous step of this loop. Proximity determinations other than the initial one take effect at the next [rendering opportunity](#)<sup>p1130</sup>. [CSSCONTAIN]<sup>p1476</sup>*

5. [Gather active resize observations at depth](#) *resizeObserverDepth* for *doc*.
6. If *doc* [has active resize observations](#):
  1. Set *resizeObserverDepth* to the result of [broadcasting active resize observations](#) given *doc*.
  2. [Continue](#).
7. Otherwise, [break](#).
3. If *doc* [has skipped resize observations](#), then [deliver resize loop error](#) given *doc*.
17. For each *doc* of *docs*, if the [focused area](#)<sup>p836</sup> of *doc* is not a [focusable area](#)<sup>p835</sup>, then run the [focusing steps](#)<sup>p842</sup> for *doc*'s [viewport](#), and set *doc*'s [relevant global object](#)<sup>p1083</sup>'s [navigation API](#)<sup>p952</sup>'s [focus changed during ongoing navigation](#)<sup>p964</sup> to false.

#### Example

For example, this might happen because an element has the [hidden](#)<sup>p824</sup> attribute added, causing it to stop [being rendered](#)<sup>p1388</sup>. It might also happen to an [input](#)<sup>p528</sup> element when the element gets [disabled](#)<sup>p601</sup>.

#### Note

*This will [usually](#)<sup>p843</sup> fire [blur](#)<sup>p1471</sup> events, and possibly [change](#)<sup>p1471</sup> events.*

#### Note

*In addition to this asynchronous fixup, if the [focused area of the document](#)<sup>p836</sup> is removed, there is a [synchronous fixup](#)<sup>p46</sup>. That one will not fire [blur](#)<sup>p1471</sup> or [change](#)<sup>p1471</sup> events.*

18. For each *doc* of *docs*, [perform pending transition operations](#) for *doc*. [CSSVIEWTRANSITIONS]<sup>p1477</sup>
19. For each *doc* of *docs*, [run the update intersection observations steps](#) for *doc*, passing in the [relative high resolution time](#) given *now* and *doc*'s [relevant global object](#)<sup>p1083</sup> as the timestamp. [INTERSECTIONOBSERVER]<sup>p1479</sup>
20. For each *doc* of *docs*, [record rendering time](#) for *doc* given *unsafeStyleAndLayoutStartTime*.
21. For each *doc* of *docs*, [mark paint timing](#) for *doc*.
22. For each *doc* of *docs*, update the rendering or user interface of *doc* and its [node navigable](#)<sup>p989</sup> to reflect the current state.
23. For each *doc* of *docs*, [process top layer removals](#) given *doc*.

A [navigable](#)<sup>p989</sup> has a **rendering opportunity** if the user agent is currently able to present the contents of the [navigable](#)<sup>p989</sup> to the user, accounting for hardware refresh rate constraints and user agent throttling for performance reasons, but considering content presentable even if it's outside the viewport.

A [navigable](#)<sup>p989</sup>'s [rendering opportunities](#)<sup>p1130</sup> are determined based on hardware constraints such as display refresh rates and other factors such as page performance or whether its [active document](#)<sup>p989</sup>'s [visibility state](#)<sup>p826</sup> is "visible". Rendering opportunities typically occur at regular intervals.

## Note

This specification does not mandate any particular model for selecting rendering opportunities. But for example, if the browser is attempting to achieve a 60Hz refresh rate, then rendering opportunities occur at a maximum of every 60th of a second (about 16.7ms). If the browser finds that a [navigable<sup>p989</sup>](#) is not able to sustain this rate, it might drop to a more sustainable 30 rendering opportunities per second for that [navigable<sup>p989</sup>](#), rather than occasionally dropping frames. Similarly, if a [navigable<sup>p989</sup>](#) is not visible, the user agent might decide to drop that page to a much slower 4 rendering opportunities per second, or even less.

When a user agent is to **perform a microtask checkpoint**:

1. If the [event loop<sup>p1123</sup>](#)'s [performing a microtask checkpoint<sup>p1125</sup>](#) is true, then return.
2. Set the [event loop<sup>p1123</sup>](#)'s [performing a microtask checkpoint<sup>p1125</sup>](#) to true.
3. While the [event loop<sup>p1123</sup>](#)'s [microtask queue<sup>p1124</sup>](#) is not empty:
  1. Let *oldestMicrotask* be the result of [dequeuing](#) from the [event loop<sup>p1123</sup>](#)'s [microtask queue<sup>p1124</sup>](#).
  2. Set the [event loop<sup>p1123</sup>](#)'s [currently running task<sup>p1124</sup>](#) to *oldestMicrotask*.
  3. Run *oldestMicrotask*.

## Note

This might involve invoking scripted callbacks, which eventually calls the [clean up after running script<sup>p1097</sup>](#) steps, which call this [perform a microtask checkpoint<sup>p1131</sup>](#) algorithm again, which is why we use the [performing a microtask checkpoint<sup>p1125</sup>](#) flag to avoid reentrancy.

4. Set the [event loop<sup>p1123</sup>](#)'s [currently running task<sup>p1124</sup>](#) back to null.
4. For each [environment settings object<sup>p1076</sup>](#) *settingsObject* whose [responsible event loop<sup>p1076</sup>](#) is this [event loop<sup>p1123</sup>](#), [notify about rejected promises<sup>p1100</sup>](#) given *settingsObject*'s [global object<sup>p1077</sup>](#).
5. [Cleanup Indexed Database transactions](#).
6. Perform [ClearKeptObjects\(\)](#).

## Note

When [WeakRef.prototype.deref\(\)](#) returns an object, that object is kept alive until the next invocation of [ClearKeptObjects\(\)](#), after which it is again subject to garbage collection.

7. Set the [event loop<sup>p1123</sup>](#)'s [performing a microtask checkpoint<sup>p1125</sup>](#) to false.
8. [Record timing info for microtask checkpoint](#).

When an algorithm running [in parallel<sup>p43</sup>](#) is to **await a stable state**, the user agent must [queue a microtask<sup>p1125</sup>](#) that runs the following steps, and must then stop executing (execution of the algorithm resumes when the microtask is run, as described in the following steps):

1. Run the algorithm's **synchronous section**.
2. Resumes execution of the algorithm [in parallel<sup>p43</sup>](#), if appropriate, as described in the algorithm's steps.

## Note

Steps in [synchronous sections<sup>p1131</sup>](#) are marked with .

Algorithm steps that say to **spin the event loop** until a condition *goal* is met are equivalent to substituting in the following algorithm steps:

1. Let task be the [event loop<sup>p1123</sup>](#)'s [currently running task<sup>p1124</sup>](#).

## Note

task could be a [microtask<sup>p1124</sup>](#).

2. Let *task source* be *task*'s [source](#)<sup>p1124</sup>.
3. Let *old stack* be a copy of the [JavaScript execution context stack](#).
4. Empty the [JavaScript execution context stack](#).
5. [Perform a microtask checkpoint](#)<sup>p1131</sup>.

**Note**

*If *task* is a [microtask](#)<sup>p1124</sup> this step will be a no-op due to [performing a microtask checkpoint](#)<sup>p1125</sup> being true.*

6. [In parallel](#)<sup>p43</sup>:
  1. Wait until the condition *goal* is met.
  2. [Queue a task](#)<sup>p1125</sup> on *task source* to:
    1. Replace the [JavaScript execution context stack](#) with *old stack*.
    2. Perform any steps that appear after this [spin the event loop](#)<sup>p1131</sup> instance in the original algorithm.

**Note**

*This resumes *task*.*

7. Stop *task*, allowing whatever algorithm that invoked it to resume.

**Note**

*This causes the [event loop](#)<sup>p1123</sup>'s main set of steps or the [perform a microtask checkpoint](#)<sup>p1131</sup> algorithm to continue.*

**Note**

*Unlike other algorithms in this and other specifications, which behave similar to programming-language function calls, [spin the event loop](#)<sup>p1131</sup> is more like a macro, which saves typing and indentation at the usage site by expanding into a series of steps and operations.*

**Example**

An algorithm whose steps are:

1. Do something.
2. [Spin the event loop](#)<sup>p1131</sup> until awesomeness happens.
3. Do something else.

is a shorthand which, after "macro expansion", becomes

1. Do something.
2. Let *old stack* be a copy of the [JavaScript execution context stack](#).
3. Empty the [JavaScript execution context stack](#).
4. [Perform a microtask checkpoint](#)<sup>p1131</sup>.
5. [In parallel](#)<sup>p43</sup>:
  1. Wait until awesomeness happens.
  2. [Queue a task](#)<sup>p1125</sup> on the task source in which "do something" was done to:
    1. Replace the [JavaScript execution context stack](#) with *old stack*.
    2. Do something else.

**Example**

Here is a more full example of the substitution, where the event loop is spun from inside a task that is queued from work in parallel. The version using [spin the event loop](#)<sup>p1131</sup>:

1. [In parallel](#)<sup>p43</sup>:
  1. Do parallel thing 1.
  2. [Queue a task](#)<sup>p1125</sup> on the [DOM manipulation task source](#)<sup>p1134</sup> to:
    1. Do task thing 1.
    2. [Spin the event loop](#)<sup>p1131</sup> until awesomeness happens.
    3. Do task thing 2.
  3. Do parallel thing 2.

The fully expanded version:

1. [In parallel](#)<sup>p43</sup>:
  1. Do parallel thing 1.
  2. Let *old stack* be null.
  3. [Queue a task](#)<sup>p1125</sup> on the [DOM manipulation task source](#)<sup>p1134</sup> to:
    1. Do task thing 1.
    2. Set *old stack* to a copy of the [JavaScript execution context stack](#).
    3. Empty the [JavaScript execution context stack](#).
    4. [Perform a microtask checkpoint](#)<sup>p1131</sup>.
  4. Wait until awesomeness happens.
  5. [Queue a task](#)<sup>p1125</sup> on the [DOM manipulation task source](#)<sup>p1134</sup> to:
    1. Replace the [JavaScript execution context stack](#) with *old stack*.
    2. Do task thing 2.
  6. Do parallel thing 2.

Some of the algorithms in this specification, for historical reasons, require the user agent to **pause** while running a [task](#)<sup>p1124</sup> until a condition *goal* is met. This means running the following steps:

1. Let *global* be the [current global object](#)<sup>p1083</sup>.
2. Let *timeBeforePause* be the [current high resolution time](#) given *global*.
3. If necessary, update the rendering or user interface of any [Document](#)<sup>p130</sup> or [navigable](#)<sup>p989</sup> to reflect the current state.
4. Wait until the condition *goal* is met. While a user agent has a paused [task](#)<sup>p1124</sup>, the corresponding [event loop](#)<sup>p1123</sup> must not run further [tasks](#)<sup>p1124</sup>, and any script in the currently running [task](#)<sup>p1124</sup> must block. User agents should remain responsive to user input while paused, however, albeit in a reduced capacity since the [event loop](#)<sup>p1123</sup> will not be doing anything.
5. [Record pause duration](#) given the [duration from](#) *timeBeforePause* to the [current high resolution time](#) given *global*.

**⚠Warning!**

**[Pausing](#)<sup>p1133</sup> is highly detrimental to the user experience, especially in scenarios where a single [event loop](#)<sup>p1123</sup> is shared among multiple documents. User agents are encouraged to experiment with alternatives to [pausing](#)<sup>p1133</sup>, such as [spinning the event loop](#)<sup>p1131</sup> or even simply proceeding without any kind of suspended execution at all, insofar as it is possible to do so while preserving compatibility with existing content. This specification will happily**

*change if a less-drastic alternative is discovered to be web-compatible.*

*In the interim, implementers should be aware that the variety of alternatives that user agents might experiment with can change subtle aspects of [event loop<sup>p1123</sup>](#) behavior, including [task<sup>p1124</sup>](#) and [microtask<sup>p1124</sup>](#) timing. Implementations should continue experimenting even if doing so causes them to violate the exact semantics implied by the [pause<sup>p1133</sup>](#) operation.*

#### 8.1.7.4 Generic task sources §<sup>p11</sup> 34

The following [task sources<sup>p1124</sup>](#) are used by a number of mostly unrelated features in this and other specifications.

##### The DOM manipulation task source

This [task source<sup>p1124</sup>](#) is used for features that react to DOM manipulations, such as things that happen in a non-blocking fashion when an element is [inserted into the document<sup>p46</sup>](#).

##### The user interaction task source

This [task source<sup>p1124</sup>](#) is used for features that react to user interaction, for example keyboard or mouse input.

Events sent in response to user input (e.g. [click](#) events) must be fired using [tasks<sup>p1124</sup>](#) [queued<sup>p1125</sup>](#) with the [user interaction task source<sup>p1134</sup>](#). [\[UIEVENTS\]<sup>p1483</sup>](#)

##### The networking task source

This [task source<sup>p1124</sup>](#) is used for features that trigger in response to network activity.

##### The navigation and traversal task source

This [task source<sup>p1124</sup>](#) is used to queue tasks involved in [navigation<sup>p1014</sup>](#) and [history traversal<sup>p1040</sup>](#).

##### The rendering task source

This [task source<sup>p1124</sup>](#) is used solely to [update the rendering<sup>p1128</sup>](#).

#### 8.1.7.5 Dealing with the event loop from other specifications §<sup>p11</sup> 34

Writing specifications that correctly interact with the [event loop<sup>p1123</sup>](#) can be tricky. This is compounded by how this specification uses concurrency-model-independent terminology, so we say things like "[event loop<sup>p1123</sup>](#)" and "[in parallel<sup>p43</sup>](#)" instead of using more familiar model-specific terms like "main thread" or "on a background thread".

By default, specification text generally runs on the [event loop<sup>p1123</sup>](#). This falls out from the formal [event loop processing model<sup>p1126</sup>](#), in that you can eventually trace most algorithms back to a [task<sup>p1124</sup>](#) [queued<sup>p1125</sup>](#) there.

##### Example

The algorithm steps for any JavaScript method will be invoked by author code calling that method. And author code can only be run via queued tasks, usually originating somewhere in the [script processing model<sup>p659</sup>](#).

From this starting point, the overriding guideline is that any work a specification needs to perform that would otherwise block the [event loop<sup>p1123</sup>](#) must instead be performed [in parallel<sup>p43</sup>](#) with it. This includes (but is not limited to):

- performing heavy computation;
- displaying a user-facing prompt;
- performing operations which could require involving outside systems (i.e. "going out of process").

The next complication is that, in algorithm sections that are [in parallel<sup>p43</sup>](#), you must not create or manipulate objects associated to a specific [realm<sup>p1076</sup>](#), [global<sup>p1076</sup>](#), or [environment settings object<sup>p1076</sup>](#). (Stated in more familiar terms, you must not directly access main-thread artifacts from a background thread.) Doing so would create data races observable to JavaScript code, since after all, your algorithm steps are running [in parallel<sup>p43</sup>](#) to the JavaScript code.

You can, however, manipulate specification-level data structures and values from *Infra*, as those are realm-agnostic. They are never

directly exposed to JavaScript without a specific conversion taking place (often [via Web IDL](#)). [\[INFRA\]<sup>p1479</sup>](#) [\[WEBIDL\]<sup>p1483</sup>](#)

To affect the world of observable JavaScript objects, then, you must [queue a global task<sup>p1125</sup>](#) to perform any such manipulations. This ensures your steps are properly interleaved with respect to other things happening on the [event loop<sup>p1123</sup>](#). Furthermore, you must choose a [task source<sup>p1124</sup>](#) when [queuing a global task<sup>p1125</sup>](#); this governs the relative order of your steps versus others. If you are unsure which [task source<sup>p1124</sup>](#) to use, pick one of the [generic task sources<sup>p1134</sup>](#) that sounds most applicable. Finally, you must indicate which [global object<sup>p1076</sup>](#) your queued task is associated with; this ensures that if that global object is inactive, the task does not run.

#### Note

*The base primitive, on which [queue a global task<sup>p1125</sup>](#) builds, is the [queue a task<sup>p1125</sup>](#) algorithm. In general, [queue a global task<sup>p1125</sup>](#) is better because it automatically picks the right [event loop<sup>p1123</sup>](#) and, where appropriate, [document<sup>p1124</sup>](#). Older specifications often use [queue a task<sup>p1125</sup>](#) combined with the [implied event loop<sup>p1126</sup>](#) and [implied document<sup>p1126</sup>](#) concepts, but this is discouraged.*

Putting this all together, we can provide a template for a typical algorithm that needs to do work asynchronously:

1. Do any synchronous setup work, while still on the [event loop<sup>p1123</sup>](#). This may include converting [realm](#)-specific JavaScript values into realm-agnostic specification-level values.
2. Perform a set of potentially-expensive steps [in parallel<sup>p43</sup>](#), operating entirely on realm-agnostic values, and producing a realm-agnostic result.
3. [Queue a global task<sup>p1125</sup>](#), on a specified [task source<sup>p1124</sup>](#) and given an appropriate [global object<sup>p1076</sup>](#), to convert the realm-agnostic result back into observable effects on the observable world of JavaScript objects on the [event loop<sup>p1123</sup>](#).

#### Example

The following is an algorithm that "encrypts" a passed-in [list](#) of [scalar value strings](#) *input*, after parsing them as URLs:

1. Let *urls* be an empty [list](#).
2. [For each](#) *string* of *input*:
  1. Let *parsed* be the result of [encoding-parsing a URL<sup>p97</sup>](#) given *string*, relative to the [current settings object<sup>p1083</sup>](#).
  2. If *parsed* is failure, then return [a promise rejected with](#) a ["SyntaxError" DOMException](#).
  3. Let *serialized* be the result of applying the [URL serializer](#) to *parsed*.
  4. [Append](#) *serialized* to *urls*.
3. Let *realm* be the [current realm](#).
4. Let *p* be a new promise.
5. Run the following steps [in parallel<sup>p43</sup>](#):
  1. Let *encryptedURLs* be an empty [list](#).
  2. [For each](#) *url* of *urls*:
    1. Wait 100 milliseconds, so that people think we're doing heavy-duty encryption.
    2. Let *encrypted* be a new [string](#) derived from *url*, whose *n*th [code unit](#) is equal to *url*'s *n*th [code unit](#) plus 13.
    3. [Append](#) *encrypted* to *encryptedURLs*.
  3. [Queue a global task<sup>p1125</sup>](#) on the [networking task source<sup>p1134</sup>](#), given *realm*'s [global object<sup>p1077</sup>](#), to perform the following steps:
    1. Let *array* be the result of [converting](#) *encryptedURLs* to a JavaScript array, in *realm*.
    2. Resolve *p* with *array*.
6. Return *p*.

Here are several things to notice about this algorithm:

- It does its URL parsing up front, on the [event loop](#)<sup>p1123</sup>, before going to the [in parallel](#)<sup>p43</sup> steps. This is necessary, since parsing depends on the [current settings object](#)<sup>p1083</sup>, which would no longer be current after going [in parallel](#)<sup>p43</sup>.
- Alternately, it could have saved a reference to the [current settings object](#)<sup>p1083</sup>'s [API base URL](#)<sup>p1076</sup> and used it during the [in parallel](#)<sup>p43</sup> steps; that would have been equivalent. However, we recommend instead doing as much work as possible up front, as this example does. Attempting to save the correct values can be error prone; for example, if we'd saved just the [current settings object](#)<sup>p1083</sup>, instead of its [API base URL](#)<sup>p1076</sup>, there would have been a potential race.
- It implicitly passes a [list](#) of [strings](#) from the initial steps to the [in parallel](#)<sup>p43</sup> steps. This is OK, as both [lists](#) and [strings](#) are [realm](#)-agnostic.
- It performs "expensive computation" (waiting for 100 milliseconds per input URL) during the [in parallel](#)<sup>p43</sup> steps, thus not blocking the main [event loop](#)<sup>p1123</sup>.
- Promises, as observable JavaScript objects, are never created and manipulated during the [in parallel](#)<sup>p43</sup> steps. *p* is created before entering those steps, and then is manipulated during a [task](#)<sup>p1124</sup> that is [queued](#)<sup>p1125</sup> specifically for that purpose.
- The creation of a JavaScript array object also happens during the queued task, and is careful to specify which realm it creates the array in since that is no longer obvious from context.

(On these last two points, see also [whatwg/webidl issue #135](#) and [whatwg/webidl issue #371](#), where we are still mulling over the subtleties of the above promise-resolution pattern.)

Another thing to note is that, in the event this algorithm was called from a Web IDL-specified operation taking a sequence<[USVString](#)>, there was an automatic conversion from [realm](#)-specific JavaScript objects provided by the author as input, into the [realm](#)-agnostic sequence<[USVString](#)> Web IDL type, which we then treat as a [list](#) of [scalar value strings](#). So depending on how your specification is structured, there may be other implicit steps happening on the main [event loop](#)<sup>p1123</sup> that play a part in this whole process of getting you ready to go [in parallel](#)<sup>p43</sup>.

## 8.1.8 Events <sup>§ p1136</sup>

### 8.1.8.1 Event handlers <sup>§ p1136</sup>

MDN

Many objects can have **event handlers** specified. These act as non-capture [event listeners](#) for the object on which they are specified. [\[DOM\]](#)<sup>p1478</sup>

An [event handler](#)<sup>p1136</sup> is a [struct](#) with two [items](#):

- a **value**, which is either null, a callback object, or an [internal raw uncompiled handler](#)<sup>p1142</sup>. The [EventHandler](#)<sup>p1141</sup> callback function type describes how this is exposed to scripts. Initially, an [event handler](#)<sup>p1136</sup>'s [value](#)<sup>p1136</sup> must be set to null.
- a **listener**, which is either null or an [event listener](#) responsible for running [the event handler processing algorithm](#)<sup>p1140</sup>. Initially, an [event handler](#)<sup>p1136</sup>'s [listener](#)<sup>p1136</sup> must be set to null.

Event handlers are exposed in two ways.

The first way, common to all event handlers, is as an [event handler IDL attribute](#)<sup>p1137</sup>.

The second way is as an [event handler content attribute](#)<sup>p1138</sup>. Event handlers on [HTML elements](#)<sup>p45</sup> and some of the event handlers on [Window](#)<sup>p922</sup> objects are exposed in this way.

For both of these two ways, the [event handler](#)<sup>p1136</sup> is exposed through a **name**, which is a string that always starts with "on" and is followed by the name of the event for which the handler is intended.

Most of the time, the object that exposes an [event handler](#)<sup>p1136</sup> is the same as the object on which the corresponding [event listener](#) is added. However, the [body](#)<sup>p205</sup> and [frameset](#)<sup>p1433</sup> elements expose several [event handlers](#)<sup>p1136</sup> that act upon the element's [Window](#)<sup>p922</sup> object, if one exists. In either case, we call the object an [event handler](#)<sup>p1136</sup> acts upon the **target** of that [event handler](#)<sup>p1136</sup>.

To **determine the target of an event handler**, given an [EventTarget](#) object *eventTarget* on which the [event handler](#)<sup>p1136</sup> is

exposed, and an [event handler name](#)<sup>p1136</sup> *name*, the following steps are taken:

1. If *eventTarget* is not a [body](#)<sup>p205</sup> element or a [frameset](#)<sup>p1433</sup> element, then return *eventTarget*.
2. If *name* is not the name of an attribute member of the [WindowEventHandlers](#)<sup>p1147</sup> interface mixin and the [Window-reflecting body element event handler set](#)<sup>p1145</sup> does not [contain](#) *name*, then return *eventTarget*.
3. If *eventTarget*'s [node document](#) is not an [active document](#)<sup>p998</sup>, then return null.

**Note**

*This could happen if this object is a [body](#)<sup>p205</sup> element without a corresponding [Window](#)<sup>p922</sup> object, for example.*

**Note**

*This check does not necessarily prevent [body](#)<sup>p205</sup> and [frameset](#)<sup>p1433</sup> elements that are not the [body element](#)<sup>p136</sup> of their [node document](#) from reaching the next step. In particular, a [body](#)<sup>p205</sup> element created in an [active document](#)<sup>p998</sup> (perhaps with [document.createElement\(\)](#)) but not [connected](#) will also have its corresponding [Window](#)<sup>p922</sup> object as the [target](#)<sup>p1136</sup> of several [event handlers](#)<sup>p1136</sup> exposed through it.*

4. Return *eventTarget*'s [node document](#)'s [relevant global object](#)<sup>p1083</sup>.

Each [EventTarget](#) object that has one or more [event handlers](#)<sup>p1136</sup> specified has an associated **event handler map**, which is a [map](#) of strings representing [names](#)<sup>p1136</sup> of [event handlers](#)<sup>p1136</sup> to [event handlers](#)<sup>p1136</sup>.

When an [EventTarget](#) object that has one or more [event handlers](#)<sup>p1136</sup> specified is created, its [event handler map](#)<sup>p1137</sup> must be initialized such that it contains an [entry](#) for each [event handler](#)<sup>p1136</sup> that has that object as [target](#)<sup>p1136</sup>, with [items](#) in those [event handlers](#)<sup>p1136</sup> set to their initial values.

**Note**

*The order of the [entries](#) of [event handler map](#)<sup>p1137</sup> could be arbitrary. It is not observable through any algorithms that operate on the map.*

**Note**

*[Entries](#) are not created in the [event handler map](#)<sup>p1137</sup> of an object for [event handlers](#)<sup>p1136</sup> that are merely exposed on that object, but have some other object as their [targets](#)<sup>p1136</sup>.*

An **event handler IDL attribute** is an IDL attribute for a specific [event handler](#)<sup>p1136</sup>. The name of the IDL attribute is the same as the [name](#)<sup>p1136</sup> of the [event handler](#)<sup>p1136</sup>.

The getter of an [event handler IDL attribute](#)<sup>p1137</sup> with name *name*, when called, must run these steps:

1. Let *eventTarget* be the result of [determining the target of an event handler](#)<sup>p1136</sup> given this object and *name*.
2. If *eventTarget* is null, then return null.
3. Return the result of [getting the current value of the event handler](#)<sup>p1142</sup> given *eventTarget* and *name*.

The setter of an [event handler IDL attribute](#)<sup>p1137</sup> with name *name*, when called, must run these steps:

1. Let *eventTarget* be the result of [determining the target of an event handler](#)<sup>p1136</sup> given this object and *name*.
2. If *eventTarget* is null, then return.
3. If the given value is null, then [deactivate an event handler](#)<sup>p1138</sup> given *eventTarget* and *name*.
4. Otherwise:
  1. Let *handlerMap* be *eventTarget*'s [event handler map](#)<sup>p1137</sup>.
  2. Let *eventHandler* be *handlerMap*[*name*].
  3. Set *eventHandler*'s [value](#)<sup>p1136</sup> to the given value.

4. [Activate an event handler](#)<sup>p1139</sup> given *eventTarget* and *name*.

#### Note

Certain [event handler IDL attributes](#)<sup>p1137</sup> have additional requirements, in particular the [onmessage](#)<sup>p1205</sup> attribute of [MessagePort](#)<sup>p1205</sup> objects.

An **event handler content attribute** is a content attribute for a specific [event handler](#)<sup>p1136</sup>. The name of the content attribute is the same as the [name](#)<sup>p1136</sup> of the [event handler](#)<sup>p1136</sup>.

[Event handler content attributes](#)<sup>p1138</sup>, when specified, must contain valid JavaScript code which, when parsed, would match the *FunctionBody* production after [automatic semicolon insertion](#).

The following [attribute change steps](#) are used to synchronize between [event handler content attributes](#)<sup>p1138</sup> and [event handlers](#)<sup>p1136</sup>: [\[DOM\]](#)<sup>p1478</sup>

1. If *namespace* is not null, or *localName* is not the name of an [event handler content attribute](#)<sup>p1138</sup> on *element*, then return.
2. Let *eventTarget* be the result of [determining the target of an event handler](#)<sup>p1136</sup> given *element* and *localName*.
3. If *eventTarget* is null, then return.
4. If *value* is null, then [deactivate an event handler](#)<sup>p1138</sup> given *eventTarget* and *localName*.
5. Otherwise:
  1. If the [Should element's inline behavior be blocked by Content Security Policy?](#) algorithm returns "Blocked" when executed upon *element*, "script attribute", and *value*, then return. [\[CSP\]](#)<sup>p1476</sup>
  2. Let *handlerMap* be *eventTarget*'s [event handler map](#)<sup>p1137</sup>.
  3. Let *eventHandler* be *handlerMap*[*localName*].
  4. Let *location* be the script location that triggered the execution of these steps.
  5. Set *eventHandler*'s [value](#)<sup>p1136</sup> to the [internal raw uncompiled handler](#)<sup>p1142</sup> *value/location*.
  6. [Activate an event handler](#)<sup>p1139</sup> given *eventTarget* and *localName*.

#### Note

Per the DOM Standard, these steps are run even if *oldValue* and *value* are identical (setting an attribute to its current value), but not if *oldValue* and *value* are both null (removing an attribute that doesn't currently exist). [\[DOM\]](#)<sup>p1478</sup>

To **deactivate an event handler** given an [EventTarget](#) object *eventTarget* and a string *name* that is the [name](#)<sup>p1136</sup> of an [event handler](#)<sup>p1136</sup>, run these steps:

1. Let *handlerMap* be *eventTarget*'s [event handler map](#)<sup>p1137</sup>.
2. Let *eventHandler* be *handlerMap*[*name*].
3. Set *eventHandler*'s [value](#)<sup>p1136</sup> to null.
4. Let *listener* be *eventHandler*'s [listener](#)<sup>p1136</sup>.
5. If *listener* is not null, then [remove an event listener](#) with *eventTarget* and *listener*.
6. Set *eventHandler*'s [listener](#)<sup>p1136</sup> to null.

To **erase all event listeners and handlers** given an [EventTarget](#) object *eventTarget*, run these steps:

1. If *eventTarget* has an associated [event handler map](#)<sup>p1137</sup>, then for each *name* → *eventHandler* of *eventTarget*'s associated [event handler map](#)<sup>p1137</sup>, [deactivate an event handler](#)<sup>p1138</sup> given *eventTarget* and *name*.
2. [Remove all event listeners](#) given *eventTarget*.

#### Note

This algorithm is used to define `document.open()`<sup>p1151</sup>.

To **activate an event handler** given an `EventTarget` object `eventTarget` and a string `name` that is the `name`<sup>p1136</sup> of an `event handler`<sup>p1136</sup>, run these steps:

1. Let `handlerMap` be `eventTarget`'s `event handler map`<sup>p1137</sup>.
2. Let `eventHandler` be `handlerMap[name]`.
3. If `eventHandler`'s `listener`<sup>p1136</sup> is not null, then return.
4. Let `callback` be the result of creating a Web IDL `EventListener` instance representing a reference to a function of one argument that executes the steps of [the event handler processing algorithm](#)<sup>p1140</sup>, given `eventTarget`, `name`, and its argument.

The `EventListener`'s `callback context` can be arbitrary; it does not impact the steps of [the event handler processing algorithm](#)<sup>p1140</sup>. [DOM]<sup>p1478</sup>

#### Note

The `callback` is emphatically not the `event handler`<sup>p1136</sup> itself. Every event handler ends up registering the same `callback`, the algorithm defined below, which takes care of invoking the right code, and processing the code's return value.

5. Let `listener` be a new `event listener` whose `type` is the **event handler event type** corresponding to `eventHandler` and `callback` is `callback`.

#### Note

To be clear, an `event listener` is different from an `EventListener`.

6. [Add an event listener](#) with `eventTarget` and `listener`.
7. Set `eventHandler`'s `listener`<sup>p1136</sup> to `listener`.

#### Note

The event listener registration happens only if the `event handler`<sup>p1136</sup>'s `value`<sup>p1136</sup> is being set to non-null, and the `event handler`<sup>p1136</sup> is not already activated. Since listeners are called in the order they were registered, assuming no [deactivation](#)<sup>p1138</sup> occurred, the order of event listeners for a particular event type will always be:

1. the event listeners registered with `addEventListener()` before the first time the `event handler`<sup>p1136</sup>'s `value`<sup>p1136</sup> was set to non-null
2. then the callback to which it is currently set, if any
3. and finally the event listeners registered with `addEventListener()` after the first time the `event handler`<sup>p1136</sup>'s `value`<sup>p1136</sup> was set to non-null.

#### Example

This example demonstrates the order in which event listeners are invoked. If the button in this example is clicked by the user, the page will show four alerts, with the text "ONE", "TWO", "THREE", and "FOUR" respectively.

```
<button id="test">Start Demo</button>
<script>
  var button = document.getElementById('test');
  button.addEventListener('click', function () { alert('ONE') }, false);
  button.setAttribute('onclick', "alert('NOT CALLED')"); // event handler listener is registered
  here
  button.addEventListener('click', function () { alert('THREE') }, false);
  button.onclick = function () { alert('TWO') };
  button.addEventListener('click', function () { alert('FOUR') }, false);
</script>
```

However, in the following example, the event handler is [deactivated<sup>p1138</sup>](#) after its initial activation (and its event listener is removed), before being reactivated at a later time. The page will show five alerts with "ONE", "TWO", "THREE", "FOUR", and "FIVE" respectively, in order.

```
<button id="test">Start Demo</button>
<script>
  var button = document.getElementById('test');
  button.addEventListener('click', function () { alert('ONE') }, false);
  button.setAttribute('onclick', "alert('NOT CALLED')"); // event handler is activated here
  button.addEventListener('click', function () { alert('TWO') }, false);
  button.onclick = null; // but deactivated here
  button.addEventListener('click', function () { alert('THREE') }, false);
  button.onclick = function () { alert('FOUR'); }; // and re-activated here
  button.addEventListener('click', function () { alert('FIVE') }, false);
</script>
```

#### Note

The interfaces implemented by the event object do not influence whether an [event handler<sup>p1136</sup>](#) is triggered or not.

**The event handler processing algorithm** for an [EventTarget](#) object *eventTarget*, a string *name* representing the [name<sup>p1136</sup>](#) of an [event handler<sup>p1136</sup>](#), and an [Event](#) object *event* is as follows:

1. Let *callback* be the result of [getting the current value of the event handler<sup>p1142</sup>](#) given *eventTarget* and *name*.
2. If *callback* is null, then return.
3. Let *special error event handling* be true if *event* is an [ErrorEvent<sup>p1099</sup>](#) object, *event*'s *type* is "[error<sup>p1471</sup>](#)", and *event*'s *currentTarget* implements the [WindowOrWorkerGlobalScope<sup>p1148</sup>](#) mixin. Otherwise, let *special error event handling* be false.
4. Process the [Event](#) object *event* as follows:

#### ↳ If *special error event handling* is true

Let *return value* be the result of [invoking callback](#) with « *event*'s [message<sup>p1100</sup>](#), *event*'s [filename<sup>p1100</sup>](#), *event*'s [lineno<sup>p1100</sup>](#), *event*'s [colno<sup>p1100</sup>](#), *event*'s [error<sup>p1100</sup>](#) », "rethrow", and with [callback this value](#) set to *event*'s *currentTarget*.

#### ↳ Otherwise

Let *return value* be the result of [invoking callback](#) with « *event* », "rethrow", and with [callback this value](#) set to *event*'s *currentTarget*.

#### Note

If an exception gets thrown by the callback, it will be rethrown, ending these steps. The exception will propagate to the [DOM event dispatch logic](#), which will then [report<sup>p1098</sup>](#) it.

5. Process *return value* as follows:

#### ↳ If *event* is a [BeforeUnloadEvent<sup>p983</sup>](#) object and *event*'s *type* is "[beforeunload<sup>p1471</sup>](#)"

#### Note

In this case, the [event handler IDL attribute<sup>p1137</sup>](#)'s type will be [OnBeforeUnloadEventHandler<sup>p1141</sup>](#), so *return value* will have been coerced into either null or a [DOMString](#).

If *return value* is not null, then:

1. Set *event*'s [canceled flag](#).
2. If *event*'s [returnValue<sup>p983</sup>](#) attribute's value is the empty string, then set *event*'s [returnValue<sup>p983</sup>](#) attribute's value to *return value*.

↪ **If special error event handling is true**

If return value is true, then set event's [canceled flag](#).

↪ **Otherwise**

If return value is false, then set event's [canceled flag](#).

**Note**

If we've gotten to this "Otherwise" clause because event's type is "[beforeunload](#)<sup>p1471</sup>" but event is not a [BeforeUnloadEvent](#)<sup>p983</sup> object, then return value will never be false, since in such cases return value will have been coerced into either null or a [DOMString](#).

The [EventHandler](#)<sup>p1141</sup> callback function type represents a callback used for event handlers. It is represented in Web IDL as follows:

```
IDL [LegacyTreatNonObjectAsNull]
callback EventHandlerNonNull = any (Event event);
typedef EventHandlerNonNull? EventHandler;
```

**Note**

In JavaScript, any [Function](#) object implements this interface.

**Example**

For example, the following document fragment:

```
<body onload="alert(this)" onclick="alert(this)">
```

...leads to an alert saying "[object Window]" when the document is loaded, and an alert saying "[object HTMLBodyElement]" whenever the user clicks something in the page.

**Note**

The return value of the function affects whether the event is canceled or not: as described above, if the return value is false, the event is canceled.

There are two exceptions in the platform, for historical reasons:

- The [onerror](#)<sup>p1145</sup> handlers on global objects, where returning true cancels the event.
- The [onbeforeunload](#)<sup>p1145</sup> handler, where returning any non-null and non-undefined value will cancel the event.

For historical reasons, the [onerror](#)<sup>p1145</sup> handler has different arguments:

```
IDL [LegacyTreatNonObjectAsNull]
callback OnErrorEventHandlerNonNull = any ((Event or DOMString) event, optional DOMString source,
optional unsigned long lineno, optional unsigned long colno, optional any error);
typedef OnErrorEventHandlerNonNull? OnErrorEventHandler;
```

**Example**

```
window.onerror = (message, source, lineno, colno, error) => { ... };
```

Similarly, the [onbeforeunload](#)<sup>p1145</sup> handler has a different return value:

```
IDL [LegacyTreatNonObjectAsNull]
callback OnBeforeUnloadEventHandlerNonNull = DOMString? (Event event);
typedef OnBeforeUnloadEventHandlerNonNull? OnBeforeUnloadEventHandler;
```

An **internal raw uncompiled handler** is a tuple with the following information:

- An uncompiled script body
- A location where the script body originated, in case an error needs to be reported

When the user agent is to **get the current value of the event handler** given an **EventTarget** object *eventTarget* and a string *name* that is the [name<sup>p1136</sup>](#) of an [event handler<sup>p1136</sup>](#), it must run these steps:

1. Let *handlerMap* be *eventTarget*'s [event handler map<sup>p1137</sup>](#).
2. Let *eventHandler* be *handlerMap*[*name*].
3. If *eventHandler*'s [value<sup>p1136</sup>](#) is an [internal raw uncompiled handler<sup>p1142</sup>](#), then:
  1. If *eventTarget* is an element, then let *element* be *eventTarget*, and *document* be *element*'s [node document](#). Otherwise, *eventTarget* is a [Window<sup>p922</sup>](#) object, let *element* be null, and *document* be *eventTarget*'s [associated Document<sup>p923</sup>](#).
  2. If [scripting is disabled<sup>p1083</sup>](#) for *document*, then return null.
  3. Let *body* be the uncompiled script body in *eventHandler*'s [value<sup>p1136</sup>](#).
  4. Let *location* be the location where the script body originated, as given by *eventHandler*'s [value<sup>p1136</sup>](#).
  5. If *element* is not null and *element* has a [form owner<sup>p598</sup>](#), let *form owner* be that [form owner<sup>p598</sup>](#). Otherwise, let *form owner* be null.
  6. Let *settings object* be the [relevant settings object<sup>p1083</sup>](#) of *document*.
  7. If *body* is not parsable as [FunctionBody](#) or if parsing detects an [early error](#), then follow these substeps:
    1. Set *eventHandler*'s [value<sup>p1136</sup>](#) to null.

#### Note

*This does not [deactivate<sup>p1138</sup>](#) the event handler, which additionally [removes the event handler's listener<sup>p1136</sup>](#) (if present).*

2. Let *syntaxError* be a new [SyntaxError](#) exception associated with *settings object*'s [realm<sup>p1077</sup>](#) which describes the error while parsing. It should be based on *location*, where the script body originated.
  3. [Report an exception<sup>p1098</sup>](#) with *syntaxError* for *settings object*'s [global object<sup>p1077</sup>](#).
  4. Return null.
8. Push *settings object*'s [realm execution context<sup>p1076</sup>](#) onto the [JavaScript execution context stack](#); it is now the [running JavaScript execution context](#).

#### Note

*This is necessary so the subsequent invocation of [OrdinaryFunctionCreate](#) takes place in the correct [realm](#).*

9. Let *function* be the result of calling [OrdinaryFunctionCreate](#), with arguments:

#### **functionPrototype**

[%Function.prototype%](#)

#### **sourceText**

↪ If *name* is [onerror<sup>p1145</sup>](#) and *eventTarget* is a [Window<sup>p922</sup>](#) object

The string formed by concatenating "function ", *name*, "(event, source, lineno, colno, error) {", U+000A LF, *body*, U+000A LF, and "}".

↪ Otherwise

The string formed by concatenating "function ", *name*, "(event) {", U+000A LF, *body*, U+000A LF, and "}".

#### **ParameterList**

↪ If *name* is [onerror<sup>p1145</sup>](#) and *eventTarget* is a [Window<sup>p922</sup>](#) object

Let the function have five arguments, named *event*, *source*, *lineno*, *colno*, and *error*.

↪ **Otherwise**

Let the function have a single argument called *event*.

**body**

The result of parsing *body* above.

**thisMode**

non-lexical-this

**scope**

1. Let *realm* be *settings object*'s [realm](#)<sup>p1077</sup>.
  2. Let *scope* be *realm*.[[GlobalEnv]].
  3. If *eventHandler* is an element's [event handler](#)<sup>p1136</sup>, then set *scope* to [NewObjectEnvironment](#)(*document*, true, *scope*).  
(Otherwise, *eventHandler* is a [Window](#)<sup>p922</sup> object's [event handler](#)<sup>p1136</sup>.)
  4. If *form owner* is not null, then set *scope* to [NewObjectEnvironment](#)(*form owner*, true, *scope*).
  5. If *element* is not null, then set *scope* to [NewObjectEnvironment](#)(*element*, true, *scope*).
  6. Return *scope*.
10. Remove *settings object*'s [realm execution context](#)<sup>p1076</sup> from the [JavaScript execution context stack](#).
  11. Set *function*.[[ScriptOrModule]] to null.

**Note**

This is done because the default behavior, of associating the created function with the nearest [script](#)<sup>p1084</sup> on the stack, can lead to path-dependent results. For example, an event handler which is first invoked by user interaction would end up with null [[ScriptOrModule]] (since then this algorithm would be first invoked when the [active script](#)<sup>p1085</sup> is null), whereas one that is first invoked by dispatching an event from script would have its [[ScriptOrModule]] set to that script.

Instead, we just always set [[ScriptOrModule]] to null. This is more intuitive anyway; the idea that the first script which dispatches an event is somehow responsible for the event handler code is dubious.

In practice, this only affects the resolution of relative URLs via [import\(\)](#), which consult the [base URL](#)<sup>p1085</sup> of the associated script. Nulling out [[ScriptOrModule]] means that [HostLoadImportedModule](#)<sup>p1121</sup> will fall back to the [current settings object](#)<sup>p1083</sup>'s [API base URL](#)<sup>p1076</sup>.

12. Set *eventHandler*'s [value](#)<sup>p1136</sup> to the result of creating a Web IDL [EventHandler](#)<sup>p1141</sup> callback function object whose object reference is *function* and whose [callback context](#) is *settings object*.
4. Return *eventHandler*'s [value](#)<sup>p1136</sup>.

### 8.1.8.2 Event handlers on elements, [Document](#)<sup>p130</sup> objects, and [Window](#)<sup>p922</sup> objects §<sup>p11</sup><sub>43</sub>

The following are the [event handlers](#)<sup>p1136</sup> (and their corresponding [event handler event types](#)<sup>p1139</sup>) that must be supported by all [HTML elements](#)<sup>p45</sup>, as both [event handler content attributes](#)<sup>p1138</sup> and [event handler IDL attributes](#)<sup>p1137</sup>; and that must be supported by all [Document](#)<sup>p130</sup> and [Window](#)<sup>p922</sup> objects, as [event handler IDL attributes](#)<sup>p1137</sup>:

<a href="#">Event handler</a> <sup>p1136</sup>	<a href="#">Event handler event type</a> <sup>p1139</sup>
<a href="#">onabort</a>	<a href="#">abort</a>
<a href="#">onauxclick</a>	<a href="#">auxclick</a>

The following are the [event handlers](#)<sup>p1136</sup> (and their corresponding [event handler event types](#)<sup>p1139</sup>) that must be supported by all [HTML elements](#)<sup>p45</sup> other than [body](#)<sup>p205</sup> and [frameset](#)<sup>p1433</sup> elements, as both [event handler content attributes](#)<sup>p1138</sup> and [event handler IDL attributes](#)<sup>p1137</sup>; that must be supported by all [Document](#)<sup>p130</sup> objects, as [event handler IDL attributes](#)<sup>p1137</sup>; and that must be supported by all [Window](#)<sup>p922</sup> objects, as [event handler IDL attributes](#)<sup>p1137</sup> on the [Window](#)<sup>p922</sup> objects themselves, and with corresponding [event handler content attributes](#)<sup>p1138</sup> and [event handler IDL attributes](#)<sup>p1137</sup> exposed on all [body](#)<sup>p205</sup> and [frameset](#)<sup>p1433</sup> elements that are owned by that [Window](#)<sup>p922</sup> object's [associated Document](#)<sup>p923</sup>:

Event handler <sup>p1136</sup>	Event handler event type <sup>p1139</sup>
<a href="#">onblur</a>	<a href="#">blur</a> <sup>p1471</sup>
<a href="#">onerror</a>	<a href="#">error</a> <sup>p1471</sup>
<a href="#">onfocus</a>	<a href="#">focus</a> <sup>p1471</sup>
<a href="#">onload</a>	<a href="#">load</a> <sup>p1471</sup>
<a href="#">onresize</a>	<a href="#">resize</a>
<a href="#">onscroll</a>	<a href="#">scroll</a>

We call the [set](#) of the [names](#)<sup>p1136</sup> of the [event handlers](#)<sup>p1136</sup> listed in the first column of this table the **Window-reflecting body element event handler set**.

The following are the [event handlers](#)<sup>p1136</sup> (and their corresponding [event handler event types](#)<sup>p1139</sup>) that must be supported by [Window](#)<sup>p922</sup> objects, as [event handler IDL attributes](#)<sup>p1137</sup> on the [Window](#)<sup>p922</sup> objects themselves, and with corresponding [event handler content attributes](#)<sup>p1138</sup> and [event handler IDL attributes](#)<sup>p1137</sup> exposed on all [body](#)<sup>p205</sup> and [frameset](#)<sup>p1433</sup> elements that are owned by that [Window](#)<sup>p922</sup> object's [associated Document](#)<sup>p923</sup>:

Event handler <sup>p1136</sup>	Event handler event type <sup>p1139</sup>
<a href="#">onafterprint</a>	<a href="#">afterprint</a> <sup>p1471</sup>
<a href="#">onbeforeprint</a>	<a href="#">beforeprint</a> <sup>p1471</sup>
<a href="#">onbeforeunload</a>	<a href="#">beforeunload</a> <sup>p1471</sup>
<a href="#">onhashchange</a>	<a href="#">hashchange</a> <sup>p1471</sup>
<a href="#">onlanguagechange</a>	<a href="#">languagechange</a> <sup>p1471</sup>
<a href="#">onmessage</a>	<a href="#">message</a> <sup>p1471</sup>
<a href="#">onmessageerror</a>	<a href="#">messageerror</a> <sup>p1472</sup>
<a href="#">onoffline</a>	<a href="#">offline</a> <sup>p1472</sup>
<a href="#">ononline</a>	<a href="#">online</a> <sup>p1472</sup>
<a href="#">onpageswap</a>	<a href="#">pageswap</a> <sup>p1472</sup>
<a href="#">onpagehide</a>	<a href="#">pagehide</a> <sup>p1472</sup>
<a href="#">onpagereveal</a>	<a href="#">pagereveal</a> <sup>p1472</sup>
<a href="#">onpageshow</a>	<a href="#">pageshow</a> <sup>p1472</sup>
<a href="#">onpopstate</a>	<a href="#">popstate</a> <sup>p1472</sup>
<a href="#">onrejectionhandled</a>	<a href="#">rejectionhandled</a> <sup>p1472</sup>
<a href="#">onstorage</a>	<a href="#">storage</a> <sup>p1472</sup>
<a href="#">onunhandledrejection</a>	<a href="#">unhandledrejection</a> <sup>p1472</sup>
<a href="#">onunload</a>	<a href="#">unload</a> <sup>p1472</sup>

This list of [event handlers](#)<sup>p1136</sup> is reified as [event handler IDL attributes](#)<sup>p1137</sup> through the [WindowEventHandlers](#)<sup>p1147</sup> interface mixin.

The following are the [event handlers](#)<sup>p1136</sup> (and their corresponding [event handler event types](#)<sup>p1139</sup>) that must be supported on [Document](#)<sup>p130</sup> objects as [event handler IDL attributes](#)<sup>p1137</sup>:

Event handler <sup>p1136</sup>	Event handler event type <sup>p1139</sup>
<b>onreadystatechange</b>	<a href="#">readystatechange<sup>p1472</sup></a>
<b>onvisibilitychange</b>	<a href="#">visibilitychange<sup>p1472</sup></a>

### 8.1.8.3 Event firing <sup>§<sub>47</sub><sup>p11</sup></sup>

Certain operations and methods are defined as firing events on elements. For example, the `click()`<sup>p833</sup> method on the `HTMLElement`<sup>p142</sup> interface is defined as firing a `click` event on the element. [\[UIEVENTS\]](#)<sup>p1483</sup>

**Firing a synthetic pointer event named *e* at *target***, with an optional *not trusted flag*, means running these steps:

1. Let *event* be the result of [creating an event](#) using `PointerEvent`.
2. Initialize *event*'s `type` attribute to *e*.
3. Initialize *event*'s `bubbles` and `cancelable` attributes to true.
4. Set *event*'s `composed` flag.

5. If the *not trusted flag* is set, initialize event's `isTrusted` attribute to false.
6. Initialize event's `ctrlKey`, `shiftKey`, `altKey`, and `metaKey` attributes according to the current state of the key input device, if any (false for any keys that are not available).
7. Initialize event's `view` attribute to target's `node document`'s `Window`<sup>p922</sup> object, if any, and null otherwise.
8. event's `getModifierState()` method is to return values appropriately describing the current state of the key input device.
9. Return the result of `dispatching` event at target.

Firing a **click event** at target means firing a synthetic pointer event named `click`<sup>p1147</sup> at target.

## 8.2 The `WindowOrWorkerGlobalScope`<sup>p1148</sup> mixin §<sup>p1148</sup>

The `WindowOrWorkerGlobalScope`<sup>p1148</sup> mixin is for use of APIs that are to be exposed on `Window`<sup>p922</sup> and `WorkerGlobalScope`<sup>p1228</sup> objects.

### Note

Other standards are encouraged to further extend it using partial interface mixin `WindowOrWorkerGlobalScope`<sup>p1148</sup> { ... }; along with an appropriate reference.

```
IDL
typedef (DOMString or Function or TrustedScript) TimerHandler;

interface mixin WindowOrWorkerGlobalScope {
  [Replaceable] readonly attribute USVString origin;
  readonly attribute boolean isSecureContext;
  readonly attribute boolean crossOriginIsolated;

  undefined reportError(any e);

  // base64 utility methods
  DOMString btoa(DOMString data);
  ByteString atob(DOMString data);

  // timers
  long setTimeout(TimerHandler handler, optional long timeout = 0, any... arguments);
  undefined clearTimeout(optional long id = 0);
  long setInterval(TimerHandler handler, optional long timeout = 0, any... arguments);
  undefined clearInterval(optional long id = 0);

  // microtask queuing
  undefined queueMicrotask(VoidFunction callback);

  // ImageBitmap
  Promise<ImageBitmap> createImageBitmap(ImageBitmapSource image, optional ImageBitmapOptions options = {});
  Promise<ImageBitmap> createImageBitmap(ImageBitmapSource image, long sx, long sy, long sw, long sh, optional ImageBitmapOptions options = {});

  // structured cloning
  any structuredClone(any value, optional StructuredSerializeOptions options = {});
};
Window includes WindowOrWorkerGlobalScope;
WorkerGlobalScope includes WindowOrWorkerGlobalScope;
```

For web developers (non-normative)

### **self.isSecureContext**<sup>p1149</sup>

Returns whether or not this global object represents a [secure context](#)<sup>p1084</sup>. [\[SECURE-CONTEXTS\]](#)<sup>p1482</sup>

### **self.origin**<sup>p1149</sup>

Returns the global object's [origin](#)<sup>p898</sup>, serialized as string.

### **self.crossOriginIsolated**<sup>p1149</sup>

Returns whether scripts running in this global are allowed to use APIs that require cross-origin isolation. This depends on the [`Cross-Origin-Opener-Policy`](#)<sup>p984</sup> and [`Cross-Origin-Embedder-Policy`](#)<sup>p913</sup> HTTP response headers and the ["cross-origin-isolated"](#)<sup>p75</sup> feature.

## Example

Developers are strongly encouraged to use `self.origin` over `location.origin`. The former returns the [origin](#)<sup>p898</sup> of the environment, the latter of the URL of the environment. Imagine the following script executing in a document on `https://stargate.example/`:

```
var frame = document.createElement("iframe")
frame.onload = function() {
  var frameWin = frame.contentWindow
  console.log(frameWin.location.origin) // "null"
  console.log(frameWin.origin) // "https://stargate.example"
}
document.body.appendChild(frame)
```

`self.origin` is a more reliable security indicator.

The **isSecureContext** getter steps are to return true if [this's relevant settings object](#)<sup>p1083</sup> is a [secure context](#)<sup>p1084</sup>, or false otherwise.

The **origin** getter steps are to return [this's relevant settings object](#)<sup>p1083</sup>'s [origin](#)<sup>p1076</sup>, [serialized](#)<sup>p898</sup>.

The **crossOriginIsolated** getter steps are to return [this's relevant settings object](#)<sup>p1083</sup>'s [cross-origin isolated capability](#)<sup>p1076</sup>.

## 8.3 Base64 utility methods <sup>§<sup>p11</sup> 49</sup>

The [atob\(\)](#)<sup>p1150</sup> and [btoa\(\)](#)<sup>p1149</sup> methods allow developers to transform content to and from the base64 encoding.

## Note

*In these APIs, for mnemonic purposes, the "b" can be considered to stand for "binary", and the "a" for "ASCII". In practice, though, for primarily historical reasons, both the input and output of these functions are Unicode strings.*

## For web developers (non-normative)

### **result = self.btoa**<sup>p1149</sup>(data)

Takes the input data, in the form of a Unicode string containing only characters in the range U+0000 to U+00FF, each representing a binary byte with values 0x00 to 0xFF respectively, and converts it to its base64 representation, which it returns.

Throws an ["InvalidCharacterError" DOMException](#) exception if the input string contains any out-of-range characters.

### **result = self.atob**<sup>p1150</sup>(data)

Takes the input data, in the form of a Unicode string containing base64-encoded binary data, decodes it, and returns a string consisting of characters in the range U+0000 to U+00FF, each representing a binary byte with values 0x00 to 0xFF respectively, corresponding to that binary data.

Throws an ["InvalidCharacterError" DOMException](#) if the input string is not valid base64 data.

The **btoa(data)** method must throw an ["InvalidCharacterError" DOMException](#) if *data* contains any character whose code point is greater than U+00FF. Otherwise, the user agent must convert *data* to a byte sequence whose *n*th byte is the eight-bit representation of the *n*th code point of *data*, and then must apply [forgiving-base64 encode](#) to that byte sequence and return the result.

The **atob(data)** method steps are:

1. Let *decodedData* be the result of running [forgiving-base64 decode](#) on *data*.
2. If *decodedData* is failure, then throw an **"InvalidCharacterError" DOMException**.
3. Return *decodedData*.

## 8.4 Dynamic markup insertion § p1150

### Note

APIs for dynamically inserting markup into the document interact with the parser, and thus their behavior varies depending on whether they are used with [HTML documents](#) (and the [HTML parser](#)<sup>p1271</sup>) or [XML documents](#) (and the [XML parser](#)<sup>p1384</sup>).

[Document](#)<sup>p130</sup> objects have a **throw-on-dynamic-markup-insertion counter**, which is used in conjunction with the [create an element for the token](#)<sup>p1320</sup> algorithm to prevent [custom element constructors](#)<sup>p759</sup> from being able to use [document.open\(\)](#)<sup>p1151</sup>, [document.close\(\)](#)<sup>p1152</sup>, and [document.write\(\)](#)<sup>p1153</sup> when they are invoked by the parser. Initially, the counter must be set to zero.

### 8.4.1 Opening the input stream § p1150

For web developers (non-normative)

**document = document.open**<sup>p1151</sup> ()

Causes the [Document](#)<sup>p130</sup> to be replaced in-place, as if it was a new [Document](#)<sup>p130</sup> object, but reusing the previous object, which is then returned.

The resulting [Document](#)<sup>p130</sup> has an HTML parser associated with it, which can be given data to parse using [document.write\(\)](#)<sup>p1153</sup>.

The method has no effect if the [Document](#)<sup>p130</sup> is still being parsed.

Throws an **"InvalidStateError" DOMException** if the [Document](#)<sup>p130</sup> is an [XML document](#).

Throws an **"InvalidStateError" DOMException** if the parser is currently executing a [custom element constructor](#)<sup>p759</sup>.

**window = document.open**<sup>p1151</sup> (url, name, features)

Works like the [window.open\(\)](#)<sup>p926</sup> method.

[Document](#)<sup>p130</sup> objects have an **active parser was aborted** boolean, which is used to prevent scripts from invoking the [document.open\(\)](#)<sup>p1151</sup> and [document.write\(\)](#)<sup>p1153</sup> methods (directly or indirectly) after the document's [active parser](#)<sup>p134</sup> has been aborted. It is initially false.

The **document open steps**, given a *document*, are as follows:

1. If *document* is an [XML document](#), then throw an **"InvalidStateError" DOMException** exception.
2. If *document*'s [throw-on-dynamic-markup-insertion counter](#)<sup>p1150</sup> is greater than 0, then throw an **"InvalidStateError" DOMException**.
3. Let *entryDocument* be the [entry global object](#)<sup>p1080</sup>'s [associated Document](#)<sup>p923</sup>.
4. If *document*'s [origin](#) is not [same origin](#)<sup>p899</sup> to *entryDocument*'s [origin](#), then throw a **"SecurityError" DOMException**.
5. If *document* has an [active parser](#)<sup>p134</sup> whose [script nesting level](#)<sup>p1273</sup> is greater than 0, then return *document*.

### Note

This basically causes [document.open\(\)](#)<sup>p1151</sup> to be ignored when it's called in an inline script found during parsing, while still letting it have an effect when called from a non-parser task such as a timer callback or event handler.

6. Similarly, if *document*'s [unload counter](#)<sup>p1064</sup> is greater than 0, then return *document*.

#### Note

This basically causes `document.open()`<sup>p1151</sup> to be ignored when it's called from a `beforeunload`<sup>p1471</sup>, `pagehide`<sup>p1472</sup>, or `unload`<sup>p1472</sup> event handler while the `Document`<sup>p130</sup> is being unloaded.

7. If document's `active_parser_was_aborted`<sup>p1150</sup> is true, then return document.

#### Note

This notably causes `document.open()`<sup>p1151</sup> to be ignored if it is called after a `navigation`<sup>p1014</sup> has started, but only during the initial parse. See [issue #4723](#) for more background.

8. If document's `node_navigable`<sup>p989</sup> is non-null and document's `node_navigable`<sup>p989</sup>'s `ongoing_navigation`<sup>p1027</sup> is a `navigation ID`<sup>p1014</sup>, then `stop_loading`<sup>p1067</sup> document's `node_navigable`<sup>p989</sup>.
9. For each `shadow-including inclusive descendant` node of document, `erase all event listeners and handlers`<sup>p1138</sup> given node.
10. If document is the `associated Document`<sup>p923</sup> of document's `relevant global object`<sup>p1083</sup>, then `erase all event listeners and handlers`<sup>p1138</sup> given document's `relevant global object`<sup>p1083</sup>.
11. `Replace all` with null within document.
12. If document is `fully active`<sup>p1003</sup>, then:
  1. Let `newURL` be a copy of `entryDocument`'s `URL`.
  2. If `entryDocument` is not document, then set `newURL`'s `fragment` to null.
  3. Run the `URL and history update steps`<sup>p1028</sup> with document and `newURL`.
13. Set document's `is initial about:blank`<sup>p131</sup> to false.
14. If document's `iframe load in progress`<sup>p394</sup> flag is set, then set document's `mute iframe load`<sup>p394</sup> flag.
15. Set document to `no-quirks mode`.
16. Create a new `HTML parser`<sup>p1271</sup> and associate it with document. This is a **script-created parser** (meaning that it can be closed by the `document.open()`<sup>p1151</sup> and `document.close()`<sup>p1152</sup> methods, and that the tokenizer will wait for an explicit call to `document.close()`<sup>p1152</sup> before emitting an end-of-file token). The encoding `confidence`<sup>p1278</sup> is irrelevant.
17. Set the `insertion point`<sup>p1285</sup> to point at just before the end of the `input stream`<sup>p1284</sup> (which at this point will be empty).
18. `Update the current document readiness`<sup>p133</sup> of document to "loading".

#### Note

This causes a `readystatechange`<sup>p1472</sup> event to fire, but the event is actually unobservable to author code, because of the previous step which `erased all event listeners and handlers`<sup>p1138</sup> that could observe it.

19. Return document.

#### Note

The `document open steps`<sup>p1150</sup> do not affect whether a `Document`<sup>p130</sup> is `ready for post-load tasks`<sup>p1359</sup> or `completely loaded`<sup>p1063</sup>.

The `open(unused1, unused2)` method must return the result of running the `document open steps`<sup>p1150</sup> with `this`.

#### Note

The `unused1` and `unused2` arguments are ignored, but kept in the IDL to allow code that calls the function with one or two arguments to continue working. They are necessary due to Web IDL [overload resolution algorithm](#) rules, which would throw a `TypeError` exception for such calls had the arguments not been there. [whatwg/webidl issue #581](#) investigates changing the algorithm to allow for their removal. [\[WEBIDL\]](#)<sup>p1483</sup>

The `open(url, name, features)` method must run these steps:

1. If `this` is not `fully active`<sup>p1003</sup>, then throw an `"InvalidAccessError" DOMException` exception.
2. Return the result of running the `window open steps`<sup>p925</sup> with `url`, `name`, and `features`.

## 8.4.2 Closing the input stream § p11 52

For web developers (non-normative)

**document.close<sup>p1152</sup>()**

Closes the input stream that was opened by the [document.open\(\)<sup>p1151</sup>](#) method.

Throws an ["InvalidStateError" DOMException](#) if the [Document<sup>p130</sup>](#) is an [XML document](#).

Throws an ["InvalidStateError" DOMException](#) if the parser is currently executing a [custom element constructor<sup>p759</sup>](#).

The **close()** method must run the following steps:

1. If [this](#) is an [XML document](#), then throw an ["InvalidStateError" DOMException](#).
2. If [this](#)'s [throw-on-dynamic-markup-insertion counter<sup>p1150</sup>](#) is greater than zero, then throw an ["InvalidStateError" DOMException](#).
3. If there is no [script-created parser<sup>p1151</sup>](#) associated with [this](#), then return.
4. Insert an [explicit "EOF" character<sup>p1285</sup>](#) at the end of the parser's [input stream<sup>p1284</sup>](#).
5. If [this](#)'s [pending parsing-blocking script<sup>p665</sup>](#) is not null, then return.
6. Run the tokenizer, processing resulting tokens as they are emitted, and stopping when the tokenizer reaches the [explicit "EOF" character<sup>p1285</sup>](#) or [spins the event loop<sup>p1131</sup>](#).

## 8.4.3 document.write()<sup>p1153</sup> § p11 52

For web developers (non-normative)

**document.write<sup>p1153</sup>(...text)**

In general, adds the given string(s) to the [Document<sup>p130</sup>](#)'s input stream.

### ⚠Warning!

*This method has very idiosyncratic behavior. In some cases, this method can affect the state of the [HTML parser<sup>p1271</sup>](#) while the parser is running, resulting in a DOM that does not correspond to the source of the document (e.g. if the string written is the string `<plaintext>` or `<!-->`). In other cases, the call can clear the current page first, as if [document.open\(\)<sup>p1151</sup>](#) had been called. In yet more cases, the method is simply ignored, or throws an exception. Users agents are [explicitly allowed to avoid executing script elements inserted via this method<sup>p1329</sup>](#). And to make matters even worse, the exact behavior of this method can in some cases be dependent on network latency, which can lead to failures that are very hard to debug. For all these reasons, use of this method is strongly discouraged.*

Throws an ["InvalidStateError" DOMException](#) when invoked on [XML documents](#).

Throws an ["InvalidStateError" DOMException](#) if the parser is currently executing a [custom element constructor<sup>p759</sup>](#).

### ⚠Warning!

*This method performs no sanitization to remove potentially-dangerous elements and attributes like [script<sup>p652</sup>](#) or [event handler content attributes<sup>p1138</sup>](#).*

[Document<sup>p130</sup>](#) objects have an **ignore-destructive-writes counter**, which is used in conjunction with the processing of [script<sup>p652</sup>](#) elements to prevent external scripts from being able to use [document.write\(\)<sup>p1153</sup>](#) to blow away the document by implicitly calling [document.open\(\)<sup>p1151</sup>](#). Initially, the counter must be set to zero.

The **document write steps**, given a [Document<sup>p130</sup>](#) object *document*, a list *text*, a boolean *lineFeed* and a string *sink*, are as follows:

1. Let *string* be the empty string.
2. Let *isTrusted* be false if *text* [contains](#) a string; otherwise true.
3. [For each](#) value of *text*:
  1. If *value* is a [TrustedHTML](#) object, then append *value*'s associated [data](#) to *string*.

2. Otherwise, append *value* to *string*.
4. If *isTrusted* is false, set *string* to the result of invoking the [Get Trusted Type compliant string](#) algorithm with [TrustedHTML](#), [this's relevant global object](#)<sup>p1083</sup>, *string*, *sink*, and "script".
5. If *lineFeed* is true, append U+000A LINE FEED to *string*.
6. If *document* is an [XML document](#), then throw an ["InvalidStateError" DOMException](#).
7. If *document*'s [throw-on-dynamic-markup-insertion counter](#)<sup>p1150</sup> is greater than 0, then throw an ["InvalidStateError" DOMException](#).
8. If *document*'s [active parser was aborted](#)<sup>p1150</sup> is true, then return.
9. If the [insertion point](#)<sup>p1285</sup> is undefined, then:
  1. If *document*'s [unload counter](#)<sup>p1064</sup> is greater than 0 or *document*'s [ignore-destructive-writes counter](#)<sup>p1152</sup> is greater than 0, then return.
  2. Run the [document open steps](#)<sup>p1150</sup> with *document*.
10. Insert *string* into the [input stream](#)<sup>p1284</sup> just before the [insertion point](#)<sup>p1285</sup>.
11. If *document*'s [pending parsing-blocking script](#)<sup>p665</sup> is null, then have the [HTML parser](#)<sup>p1271</sup> process *string*, one code point at a time, processing resulting tokens as they are emitted, and stopping when the tokenizer reaches the insertion point or when the processing of the tokenizer is aborted by the tree construction stage (this can happen if a [script](#)<sup>p652</sup> end tag token is emitted by the tokenizer).

#### Note

If the [document.write\(\)](#)<sup>p1153</sup> method was called from script executing inline (i.e. executing because the parser parsed a set of [script](#)<sup>p652</sup> tags), then this is a [reentrant invocation of the parser](#)<sup>p1272</sup>. If the [parser pause flag](#)<sup>p1273</sup> is set, the tokenizer will abort immediately and no HTML will be parsed, per the tokenizer's [parser pause flag check](#)<sup>p1290</sup>.

The [document.write\(...text\)](#) method steps are to run the [document write steps](#)<sup>p1152</sup> with [this](#), *text*, false, and "Document write".

### 8.4.4 document.writeln()<sup>p1153</sup> §<sup>p11</sup><sub>53</sub>

For web developers (non-normative)

**document.writeln<sup>p1153</sup>(...text)**

Adds the given string(s) to the [Document](#)<sup>p139</sup>'s input stream, followed by a newline character. If necessary, calls the [open\(\)](#)<sup>p1151</sup> method implicitly first.

Throws an ["InvalidStateError" DOMException](#) when invoked on [XML documents](#).

Throws an ["InvalidStateError" DOMException](#) if the parser is currently executing a [custom element constructor](#)<sup>p759</sup>.

#### ⚠Warning!

**This method performs no sanitization to remove potentially-dangerous elements and attributes like [script](#)<sup>p652</sup> or [event handler content attributes](#)<sup>p1138</sup>.**

The [document.writeln\(...text\)](#) method steps are to run the [document write steps](#)<sup>p1152</sup> with [this](#), *text*, true, and "Document writeln".

## 8.5 DOM parsing and serialization APIs §<sup>p11</sup><sub>53</sub>

**IDL** partial interface Element {  
 [CEReactions] undefined setHTMLUnsafe((TrustedHTML or DOMString) html);  
 DOMString getHTML(optional GetHTMLOptions options = {});

```

[CEReactions] attribute (TrustedHTML or [LegacyNullToEmptyString] DOMString) innerHTML;
[CEReactions] attribute (TrustedHTML or [LegacyNullToEmptyString] DOMString) outerHTML;
[CEReactions] undefined insertAdjacentHTML(DOMString position, (TrustedHTML or DOMString) string);
};

partial interface ShadowRoot {
  [CEReactions] undefined setHTMLUnsafe((TrustedHTML or DOMString) html);
  DOMString getHTML(optional GetHTMLOptions options = {});

  [CEReactions] attribute (TrustedHTML or [LegacyNullToEmptyString] DOMString) innerHTML;
};

dictionary GetHTMLOptions {
  boolean serializableShadowRoots = false;
  sequence<ShadowRoot> shadowRoots = [];
};

```

### 8.5.1 The [DOMParser](#)<sup>p1154</sup> interface § p1154

The [DOMParser](#)<sup>p1154</sup> interface allows authors to create new [Document](#)<sup>p130</sup> objects by parsing strings, as either HTML or XML.

For web developers (non-normative)

**`parser = new DOMParserp1155()`**

Constructs a new [DOMParser](#)<sup>p1154</sup> object.

**`document = parser.parseFromStringp1155(string, type)`**

Parses *string* using either the HTML or XML parser, according to *type*, and returns the resulting [Document](#)<sup>p130</sup>. *type* can be "[text/html](#)<sup>p1444</sup>" (which will invoke the HTML parser), or any of "[text/xml](#)<sup>p1474</sup>", "[application/xml](#)<sup>p1473</sup>", "[application/xhtml+xml](#)<sup>p1446</sup>", or "[image/svg+xml](#)<sup>p1473</sup>" (which will invoke the XML parser).

For the XML parser, if *string* cannot be parsed, then the returned [Document](#)<sup>p130</sup> will contain elements describing the resulting error.

Note that [script](#)<sup>p652</sup> elements are not evaluated during parsing, and the resulting document's [encoding](#) will always be [UTF-8](#). The document's [URL](#) will be inherited from *parser*'s [relevant global object](#)<sup>p1083</sup>.

Values other than the above for *type* will cause a [TypeError](#) exception to be thrown.

#### Note

The design of [DOMParser](#)<sup>p1154</sup>, as a class that needs to be constructed and then have its [parseFromString\(\)](#)<sup>p1155</sup> method called, is an unfortunate historical artifact. If we were designing this functionality today it would be a standalone function. For parsing HTML, the modern alternative is [Document.parseHTMLUnsafe\(\)](#)<sup>p1156</sup>.

#### Warning!

**This method performs no sanitization to remove potentially-dangerous elements and attributes like [script](#)<sup>p652</sup> or [event handler content attributes](#)<sup>p1138</sup>.**

IDL

```

[Exposed=Window]
interface DOMParser {
  constructor();

  [NewObject] Document parseFromString((TrustedHTML or DOMString) string, DOMParserSupportedType type);
};

enum DOMParserSupportedType {
  "text/html",
  "text/xml",
  "application/xml",

```

```
"application/xhtml+xml",  
"image/svg+xml"  
};
```

The **new DOMParser()** constructor steps are to do nothing.

The **parseFromString(string, type)** method steps are:

1. Let *compliantString* be the result of invoking the [Get Trusted Type compliant string](#) algorithm with [TrustedHTML](#), [this's relevant global object](#)<sup>p1083</sup>, *string*, "DOMParser parseFromString", and "script".
2. Let *document* be a new [Document](#)<sup>p130</sup>, whose [content type](#) is *type* and [URL](#) is [this's relevant global object](#)<sup>p1083</sup>'s [associated Document](#)<sup>p923</sup>'s [URL](#).

**Note**

The document's [encoding](#) will be left as its default, of [UTF-8](#). In particular, any XML declarations or [meta](#)<sup>p189</sup> elements found while parsing *compliantString* will have no effect.

3. Switch on *type*:

↪ **"text/html"**

1. [Parse HTML from a string](#)<sup>p1155</sup> given *document* and *compliantString*.

**Note**

Since *document* does not have a [browsing context](#)<sup>p999</sup>, [scripting is disabled](#)<sup>p1083</sup>.

↪ **Otherwise**

1. Create an [XML parser](#)<sup>p1384</sup> *parser*, associated with *document*, and with [XML scripting support disabled](#)<sup>p1385</sup>.
2. Parse *compliantString* using *parser*.
3. If the previous step resulted in an XML well-formedness or XML namespace well-formedness error, then:
  1. [Assert](#): *document* has no child nodes.
  2. Let *root* be the result of [creating an element](#) given *document*, "parsererror", and "http://www.mozilla.org/newlayout/xml/parsererror.xml".
  3. Optionally, add attributes or children to *root* to describe the nature of the parsing error.
  4. [Append](#) *root* to *document*.

4. Return *document*.

To **parse HTML from a string**, given a [Document](#)<sup>p130</sup> *document* and a [string](#) *html*:

1. Set *document*'s [type](#) to "html".
2. Create an [HTML parser](#)<sup>p1271</sup> *parser*, associated with *document*.
3. Place *html* into the [input stream](#)<sup>p1284</sup> for *parser*. The encoding [confidence](#)<sup>p1278</sup> is irrelevant.
4. Start *parser* and let it run until it has consumed all the characters just inserted into the input stream.

**Note**

This might mutate the document's [mode](#).

## 8.5.2 Unsafe HTML parsing methods §<sup>p11</sup> 55

For web developers (non-normative)

**`element.setHTMLUnsafep1156(html)`**

Parses *html* using the HTML parser, and replaces the children of *element* with the result. *element* provides context for the HTML parser.

**`shadowRoot.setHTMLUnsafep1156(html)`**

Parses *html* using the HTML parser, and replaces the children of *shadowRoot* with the result. *shadowRoot*'s [host](#) provides context for the HTML parser.

**`doc = Document.parseHTMLUnsafep1156(html)`**

Parses *html* using the HTML parser, and returns the resulting [Document<sup>p138</sup>](#).

Note that [script<sup>p652</sup>](#) elements are not evaluated during parsing, and the resulting document's [encoding](#) will always be [UTF-8](#). The document's [URL](#) will be [about:blank<sup>p53</sup>](#).

**⚠Warning!**

**These methods perform no sanitization to remove potentially-dangerous elements and attributes like [script<sup>p652</sup>](#) or [event handler content attributes<sup>p1138</sup>](#).**

[Element](#)'s **`setHTMLUnsafe(html)`** method steps are:

1. Let *compliantHTML* be the result of invoking the [Get Trusted Type compliant string](#) algorithm with [TrustedHTML](#), *this*'s [relevant global object<sup>p1083</sup>](#), *html*, "Element `setHTMLUnsafe`", and "script".
2. Let *target* be *this*'s [template contents<sup>p673</sup>](#) if *this* is a [template<sup>p671</sup>](#) element; otherwise *this*.
3. [Unsafely set HTML<sup>p1156</sup>](#) given *target*, *this*, and *compliantHTML*.

[ShadowRoot](#)'s **`setHTMLUnsafe(html)`** method steps are:

1. Let *compliantHTML* be the result of invoking the [Get Trusted Type compliant string](#) algorithm with [TrustedHTML](#), *this*'s [relevant global object<sup>p1083</sup>](#), *html*, "ShadowRoot `setHTMLUnsafe`", and "script".
2. [Unsafely set HTML<sup>p1156</sup>](#) given *this*, *this*'s [shadow host](#), and *compliantHTML*.

To **unsafely set HTML**, given an [Element](#) or [DocumentFragment](#) *target*, an [Element](#) *contextElement*, and a [string](#) *html*:

1. Let *newChildren* be the result of the [HTML fragment parsing algorithm<sup>p1373</sup>](#) given *contextElement*, *html*, and true.
2. Let *fragment* be a new [DocumentFragment](#) whose [node document](#) is *contextElement*'s [node document](#).
3. For each *node* in *newChildren*, [append](#) *node* to *fragment*.
4. [Replace all](#) with *fragment* within *target*.

The static **`parseHTMLUnsafe(html)`** method steps are:

1. Let *compliantHTML* be the result of invoking the [Get Trusted Type compliant string](#) algorithm with [TrustedHTML](#), *this*'s [relevant global object<sup>p1083</sup>](#), *html*, "Document `parseHTMLUnsafe`", and "script".
2. Let *document* be a new [Document<sup>p138</sup>](#), whose [content type](#) is "text/html".

**Note**

Since *document* does not have a [browsing context<sup>p999</sup>](#), [scripting is disabled<sup>p1083</sup>](#).

3. Set *document*'s [allow declarative shadow roots](#) to true.
4. [Parse HTML from a string<sup>p1155</sup>](#) given *document* and *compliantHTML*.
5. Return *document*.

### 8.5.3 HTML serialization methods <sup>§ p11</sup> 57

For web developers (non-normative)

```
html = element.getHTMLp1157 ({ serializableShadowRootsp1154, shadowRootsp1154 })
```

Returns the result of serializing *element* to HTML. [Shadow roots](#) within *element* are serialized according to the provided options:

- If [serializableShadowRoots<sup>p1154</sup>](#) is true, then all shadow roots marked as [serializable](#) are serialized.
- If the [shadowRoots<sup>p1154</sup>](#) array is provided, then all shadow roots specified in the array are serialized, regardless of whether or not they are marked as serializable.

If neither option is provided, then no shadow roots are serialized.

```
html = shadowRoot.getHTMLp1157 ({ serializableShadowRootsp1154, shadowRootsp1154 })
```

Returns the result of serializing *shadowRoot* to HTML, using its [shadow host](#) as the context element. [Shadow roots](#) within *shadowRoot* are serialized according to the provided options, as above.

[Element](#)'s [getHTML\(options\)](#) method steps are to return the result of [HTML fragment serialization algorithm<sup>p1368</sup>](#) with [this](#), [options\["serializableShadowRoots<sup>p1154</sup>"\]](#), and [options\["shadowRoots<sup>p1154</sup>"\]](#).

[ShadowRoot](#)'s [getHTML\(options\)](#) method steps are to return the result of [HTML fragment serialization algorithm<sup>p1368</sup>](#) with [this](#), [options\["serializableShadowRoots<sup>p1154</sup>"\]](#), and [options\["shadowRoots<sup>p1154</sup>"\]](#).

### 8.5.4 The [innerHTML<sup>p1158</sup>](#) property <sup>§ p11</sup> 57

The [innerHTML<sup>p1158</sup>](#) property has a number of outstanding issues in the [DOM Parsing and Serialization issue tracker](#), documenting various problems with its specification.

For web developers (non-normative)

```
element.innerHTMLp1158
```

Returns a fragment of HTML or XML that represents the element's contents.

In the case of an XML document, throws a ["InvalidStateError" DOMException](#) if the element cannot be serialized to XML.

```
element.innerHTMLp1158 = value
```

Replaces the contents of the element with nodes parsed from the given string.

In the case of an XML document, throws a ["SyntaxError" DOMException](#) if the given string is not well-formed.

```
shadowRoot.innerHTMLp1158
```

Returns a fragment of HTML that represents the shadow roots's contents.

```
shadowRoot.innerHTMLp1158 = value
```

Replaces the contents of the shadow root with nodes parsed from the given string.

#### ⚠Warning!

**These properties' setters perform no sanitization to remove potentially-dangerous elements and attributes like [script<sup>p652</sup>](#) or [event handler content attributes<sup>p1138</sup>](#).**

The **fragment serializing algorithm steps**, given an [Element](#), [Document<sup>p130</sup>](#) or [DocumentFragment](#) *node* and a boolean *require well-formed*, are:

1. Let *context document* be *node*'s [node document](#).
2. If *context document* is an [HTML document](#), return the result of [HTML fragment serialization algorithm<sup>p1368</sup>](#) with *node*, false, and « ».
3. Return the [XML serialization](#) of *node* given *require well-formed*.

The **fragment parsing algorithm steps**, given an [Element](#) *context* and a string *markup*, are:

1. Let *algorithm* be the [HTML fragment parsing algorithm](#)<sup>p1373</sup>.
2. If *context*'s *node document* is an [XML document](#), then set *algorithm* to the [XML fragment parsing algorithm](#)<sup>p1387</sup>.
3. Let *new children* be the result of invoking *algorithm* given *markup*, with [context](#)<sup>p1373</sup> set to *context*.
4. Let *fragment* be a new [DocumentFragment](#) whose *node document* is *context*'s *node document*.
5. [Append](#) each [Node](#) in *new children* to *fragment* (in [tree order](#)).

#### Note

This ensures the [node document](#) for the new [nodes](#) is correct.

6. Return *fragment*.

[Element](#)'s [innerHTML](#) getter steps are to return the result of running [fragment serializing algorithm steps](#)<sup>p1157</sup> with [this](#) and true.

[ShadowRoot](#)'s [innerHTML](#) getter steps are to return the result of running [fragment serializing algorithm steps](#)<sup>p1157</sup> with [this](#) and true.

[Element](#)'s [innerHTML](#)<sup>p1158</sup> setter steps are:

1. Let *compliantString* be the result of invoking the [Get Trusted Type compliant string](#) algorithm with [TrustedHTML](#), [this](#)'s [relevant global object](#)<sup>p1083</sup>, the given value, "Element innerHTML", and "script".
2. Let *context* be [this](#).
3. Let *fragment* be the result of invoking the [fragment parsing algorithm steps](#)<sup>p1157</sup> with *context* and *compliantString*.
4. If *context* is a [template](#)<sup>p671</sup> element, then set *context* to the [template](#)<sup>p671</sup> element's [template contents](#)<sup>p673</sup> (a [DocumentFragment](#)).

#### Note

Setting [innerHTML](#)<sup>p1158</sup> on a [template](#)<sup>p671</sup> element will replace all the nodes in its [template contents](#)<sup>p673</sup> rather than its children.

5. [Replace all](#) with *fragment* within *context*.

[ShadowRoot](#)'s [innerHTML](#)<sup>p1158</sup> setter steps are:

1. Let *compliantString* be the result of invoking the [Get Trusted Type compliant string](#) algorithm with [TrustedHTML](#), [this](#)'s [relevant global object](#)<sup>p1083</sup>, the given value, "ShadowRoot innerHTML", and "script".
2. Let *context* be [this](#)'s [host](#).
3. Let *fragment* be the result of invoking the [fragment parsing algorithm steps](#)<sup>p1157</sup> with *context* and *compliantString*.
4. [Replace all](#) with *fragment* within [this](#).

### 8.5.5 The [outerHTML](#)<sup>p1159</sup> property §<sup>p1158</sup>

The [outerHTML](#)<sup>p1159</sup> property has a number of outstanding issues in the [DOM Parsing and Serialization issue tracker](#), documenting various problems with its specification.

#### For web developers (non-normative)

##### **[element.outerHTML](#)**<sup>p1159</sup>

Returns a fragment of HTML or XML that represents the element and its contents.

In the case of an XML document, throws a ["InvalidStateError" DOMException](#) if the element cannot be serialized to XML.

##### **[element.outerHTML](#)**<sup>p1159</sup> = *value*

Replaces the element with nodes parsed from the given string.

In the case of an XML document, throws a ["SyntaxError" DOMException](#) if the given string is not well-formed.

Throws a ["NoModificationAllowedError" DOMException](#) if the parent of the element is a [Document](#)<sup>p130</sup>.

**⚠Warning!**

**This property's setter performs no sanitization to remove potentially-dangerous elements and attributes like [script](#)<sup>p652</sup> or [event handler content attributes](#)<sup>p1138</sup>.**

[Element](#)'s [outerHTML](#) getter steps are:

1. Let *element* be a fictional node whose only child is [this](#).
2. Return the result of running [fragment serializing algorithm steps](#)<sup>p1157</sup> with *element* and true.

[Element](#)'s [outerHTML](#)<sup>p1159</sup> setter steps are:

1. Let *compliantString* be the result of invoking the [Get Trusted Type compliant string](#) algorithm with [TrustedHTML](#), [this](#)'s [relevant global object](#)<sup>p1083</sup>, the given value, "Element outerHTML", and "script".
2. Let *parent* be [this](#)'s [parent](#).
3. If *parent* is null, return. There would be no way to obtain a reference to the nodes created even if the remaining steps were run.
4. If *parent* is a [Document](#)<sup>p130</sup>, throw a ["NoModificationAllowedError" DOMException](#).
5. If *parent* is a [DocumentFragment](#), set *parent* to the result of [creating an element](#) given [this](#)'s [node document](#), [body](#)<sup>p205</sup>, and the [HTML namespace](#).
6. Let *fragment* be the result of invoking the [fragment parsing algorithm steps](#)<sup>p1157</sup> given *parent* and *compliantString*.
7. [Replace this](#) with *fragment* within [this](#)'s [parent](#).

### 8.5.6 The [insertAdjacentHTML\(\)](#)<sup>p1160</sup> method §p1159

The [insertAdjacentHTML\(\)](#)<sup>p1160</sup> method has a number of outstanding issues in the [DOM Parsing and Serialization issue tracker](#), documenting various problems with its specification.

For web developers (non-normative)

**[element.insertAdjacentHTML\(\)](#)<sup>p1160</sup>(*position*, *string*)**

Parses *string* as HTML or XML and inserts the resulting nodes into the tree in the position given by the *position* argument, as follows:

**"beforebegin"**

Before the element itself (i.e., after *element*'s previous sibling)

**"afterbegin"**

Just inside the element, before its first child.

**"beforeend"**

Just inside the element, after its last child.

**"afterend"**

After the element itself (i.e., before *element*'s next sibling)

Throws a ["SyntaxError" DOMException](#) if the arguments have invalid values (e.g., in the case of an [XML document](#), if the given string is not well-formed).

Throws a ["NoModificationAllowedError" DOMException](#) if the given position isn't possible (e.g. inserting elements after the root element of a [Document](#)<sup>p130</sup>).

**⚠Warning!**

**This method performs no sanitization to remove potentially-dangerous elements and attributes like [script](#)<sup>p652</sup> or [event handler content attributes](#)<sup>p1138</sup>.**

`Element`'s `insertAdjacentHTML(position, string)` method steps are:

1. Let *compliantString* be the result of invoking the [Get Trusted Type compliant string](#) algorithm with `TrustedHTML`, *this*'s [relevant global object](#)<sup>p1083</sup>, *string*, "Element insertAdjacentHTML", and "script".
2. Let *context* be null.
3. Use the first matching item from this list:
  - ↪ If *position* is an **ASCII case-insensitive** match for the string "beforebegin"
    - ↪ If *position* is an **ASCII case-insensitive** match for the string "afterend"
      1. Set *context* to *this*'s [parent](#)<sup>p931</sup>.
      2. If *context* is null or a [Document](#)<sup>p139</sup>, throw a ["NoModificationAllowedError"](#) `DOMException`.
  - ↪ If *position* is an **ASCII case-insensitive** match for the string "afterbegin"
    - ↪ If *position* is an **ASCII case-insensitive** match for the string "beforeend"
      - Set *context* to *this*.
  - ↪ Otherwise
    - Throw a ["SyntaxError"](#) `DOMException`.
4. If *context* is not an `Element` or all of the following are true:
  - *context*'s [node document](#) is an HTML document;
  - *context*'s [local name](#) is `"html"`<sup>p172</sup>; and
  - *context*'s [namespace](#) is the [HTML namespace](#),set *context* to the result of [creating an element](#) given *this*'s [node document](#), [body](#)<sup>p285</sup>, and the [HTML namespace](#).
5. Let *fragment* be the result of invoking the [fragment parsing algorithm steps](#)<sup>p1157</sup> with *context* and *compliantString*.
6. Use the first matching item from this list:
  - ↪ If *position* is an **ASCII case-insensitive** match for the string "beforebegin"
    - [Insert](#) *fragment* into *this*'s [parent](#)<sup>p931</sup> before *this*.
  - ↪ If *position* is an **ASCII case-insensitive** match for the string "afterbegin"
    - [Insert](#) *fragment* into *this* before its [first child](#).
  - ↪ If *position* is an **ASCII case-insensitive** match for the string "beforeend"
    - [Append](#) *fragment* to *this*.
  - ↪ If *position* is an **ASCII case-insensitive** match for the string "afterend"
    - [Insert](#) *fragment* into *this*'s [parent](#)<sup>p931</sup> before *this*'s [next sibling](#).

#### Note

As with other direct `Node`-manipulation APIs (and unlike [innerHTML](#)<sup>p1158</sup>), [insertAdjacentHTML\(\)](#)<sup>p1160</sup> does not include any special handling for [template](#)<sup>p671</sup> elements. In most cases you will want to use `templateEl.content`<sup>p674</sup>.[insertAdjacentHTML\(\)](#)<sup>p1160</sup> instead of directly manipulating the child nodes of a [template](#)<sup>p671</sup> element.

### 8.5.7 The `createContextualFragment()`<sup>p1161</sup> method §<sup>p11</sup><sub>60</sub>

The `createContextualFragment()`<sup>p1161</sup> method has a number of outstanding issues in the [DOM Parsing and Serialization issue tracker](#), documenting various problems with its specification.

For web developers (non-normative)

**docFragment** = **range.createContextualFragment**<sup>p1161</sup>(**string**)

Returns a **DocumentFragment** created from the markup string *string* using *range*'s **start node** as the context in which *fragment* is parsed.

**⚠Warning!**

**This method performs no sanitization to remove potentially-dangerous elements and attributes like **script**<sup>p652</sup> or event handler content attributes<sup>p1138</sup>.**

**IDL** **partial interface** Range {  
 [CEReactions, NewObject] **DocumentFragment** createContextualFragment((**TrustedHTML** or **DOMString**) *string*);  
};

**Range**'s **createContextualFragment(*string*)** method steps are:

1. Let *compliantString* be the result of invoking the **Get Trusted Type compliant string** algorithm with **TrustedHTML**, *this*'s **relevant global object**<sup>p1083</sup>, *string*, "Range createContextualFragment", and "script".
2. Let *node* be *this*'s **start node**.
3. Let *element* be null.
4. If *node* **implements** **Element**, set *element* to *node*.
5. Otherwise, if *node* **implements** **Text** or **Comment**, set *element* to *node*'s **parent element**.
6. If *element* is null or all of the following are true:
  - *element*'s **node document** is an HTML document;
  - *element*'s **local name** is "**html**"<sup>p172</sup>; and
  - *element*'s **namespace** is the **HTML namespace**,then set *element* to the result of **creating an element** given *this*'s **node document**, **body**<sup>p285</sup>, and the **HTML namespace**.
7. Let *fragment node* be the result of invoking the **fragment parsing algorithm steps**<sup>p1157</sup> with *element* and *compliantString*.
8. **For each** *script* of *fragment node*'s **script**<sup>p652</sup> element **descendants**:
  1. Set *script*'s **already started**<sup>p659</sup> to false.
  2. Set *script*'s **parser document**<sup>p659</sup> to null.
9. Return *fragment node*.

## 8.6 Timers §<sup>p11</sup> 61

The **setTimeout()**<sup>p1162</sup> and **setInterval()**<sup>p1162</sup> methods allow authors to schedule timer-based callbacks.

**For web developers (non-normative)**

**id** = **self.setTimeout**<sup>p1162</sup>(*handler* [, *timeout* [, ...*arguments* ] ])

Schedules a timeout to run *handler* after *timeout* milliseconds. Any *arguments* are passed straight through to the *handler*.

**id** = **self.setTimeout**<sup>p1162</sup>(*code* [, *timeout* ])

Schedules a timeout to compile and run *code* after *timeout* milliseconds.

**self.clearTimeout**<sup>p1162</sup>(*id*)

Cancels the timeout set with **setTimeout()**<sup>p1162</sup> or **setInterval()**<sup>p1162</sup> identified by *id*.

**id** = **self.setInterval**<sup>p1162</sup>(*handler* [, *timeout* [, ...*arguments* ] ])

Schedules a timeout to run *handler* every *timeout* milliseconds. Any *arguments* are passed straight through to the *handler*.

```
id = self.setIntervalp1162(code [, timeout ])
```

Schedules a timeout to compile and run *code* every *timeout* milliseconds.

```
self.clearIntervalp1162(id)
```

Cancels the timeout set with [setInterval\(\)](#)<sup>p1162</sup> or [setTimeout\(\)](#)<sup>p1162</sup> identified by *id*.

#### Note

*Timers can be nested; after five such nested timers, however, the interval is forced to be at least four milliseconds.*

#### Note

*This API does not guarantee that timers will run exactly on schedule. Delays due to CPU load, other tasks, etc, are to be expected.*

Objects that implement the [WindowOrWorkerGlobalScope](#)<sup>p1148</sup> mixin have a **map of setTimeout and setInterval IDs**, which is an [ordered map](#), initially empty. Each **key** in this map is a positive integer, corresponding to the return value of a [setTimeout\(\)](#)<sup>p1162</sup> or [setInterval\(\)](#)<sup>p1162</sup> call. Each **value** is a [unique internal value](#)<sup>p96</sup>, corresponding to a key in the object's [map of active timers](#)<sup>p1164</sup>.

The [setTimeout\(handler, timeout, ...arguments\)](#) method steps are to return the result of running the [timer initialization steps](#)<sup>p1162</sup> given *this*, *handler*, *timeout*, *arguments*, and false.

The [setInterval\(handler, timeout, ...arguments\)](#) method steps are to return the result of running the [timer initialization steps](#)<sup>p1162</sup> given *this*, *handler*, *timeout*, *arguments*, and true.

The [clearTimeout\(id\)](#) and [clearInterval\(id\)](#) method steps are to [remove this's map of setTimeout and setInterval IDs](#)<sup>p1162</sup>[*id*].

#### Note

*Because [clearTimeout\(\)](#)<sup>p1162</sup> and [clearInterval\(\)](#)<sup>p1162</sup> clear entries from the same map, either method can be used to clear timers created by [setTimeout\(\)](#)<sup>p1162</sup> or [setInterval\(\)](#)<sup>p1162</sup>.*

To perform the **timer initialization steps**, given a [WindowOrWorkerGlobalScope](#)<sup>p1148</sup> *global*, a string or [Function](#) or [TrustedScript](#) *handler*, a number *timeout*, a list *arguments*, a boolean *repeat*, and optionally (and only if *repeat* is true) a number *previousId*, perform the following steps. They return a number.

1. Let *thisArg* be *global* if that is a [WorkerGlobalScope](#)<sup>p1228</sup> object; otherwise let *thisArg* be the [WindowProxy](#)<sup>p934</sup> that corresponds to *global*.
2. If *previousId* was given, let *id* be *previousId*; otherwise, let *id* be an [implementation-defined](#) integer that is greater than zero and does not already [exist](#) in *global*'s [map of setTimeout and setInterval IDs](#)<sup>p1162</sup>.
3. If the [surrounding agent](#)'s [event loop](#)<sup>p1123</sup>'s [currently running task](#)<sup>p1124</sup> is a task that was created by this algorithm, then let *nesting level* be the [task](#)<sup>p1124</sup>'s [timer nesting level](#)<sup>p1164</sup>. Otherwise, let *nesting level* be zero.

#### Note

*The task's [timer nesting level](#)<sup>p1164</sup> is used both for nested calls to [setTimeout\(\)](#)<sup>p1162</sup>, and for the repeating timers created by [setInterval\(\)](#)<sup>p1162</sup>. (Or, indeed, for any combination of the two.) In other words, it represents nested invocations of this algorithm, not of a particular method.*

4. If *timeout* is less than 0, then set *timeout* to 0.
5. If *nesting level* is greater than 5, and *timeout* is less than 4, then set *timeout* to 4.
6. Let *realm* be *global*'s [relevant realm](#)<sup>p1083</sup>.
7. Let *initiating script* be the [active script](#)<sup>p1085</sup>.
8. Let *uniqueHandle* be null.
9. Let *task* be a [task](#)<sup>p1124</sup> that runs the following substeps:
  1. **Assert**: *uniqueHandle* is a [unique internal value](#)<sup>p96</sup>, not null.

2. If *id* does not [exist](#) in *global*'s [map of setTimeout and setInterval IDs](#)<sup>p1162</sup>, then abort these steps.
3. If *global*'s [map of setTimeout and setInterval IDs](#)<sup>p1162</sup>[*id*] does not equal *uniqueHandle*, then abort these steps.

#### Note

*This accommodates for the ID having been cleared by a [clearTimeout\(\)](#)<sup>p1162</sup> or [clearInterval\(\)](#)<sup>p1162</sup> call, and being reused by a subsequent [setTimeout\(\)](#)<sup>p1162</sup> or [setInterval\(\)](#)<sup>p1162</sup> call.*

4. [Record timing info for timer handler](#) given *handler*, *global*'s [relevant settings object](#)<sup>p1083</sup>, and *repeat*.
5. If *handler* is a [Function](#), then [invoke](#) *handler* given *arguments* and "report", and with [callback this value](#) set to *thisArg*.
6. Otherwise:
  1. If *previousId* was not given:
    1. Let *globalName* be "Window" if *global* is a [Window](#)<sup>p922</sup> object; "Worker" otherwise.
    2. Let *methodName* be "setInterval" if *repeat* is true; "setTimeout" otherwise.
    3. Let *sink* be a concatenation of *globalName*, U+0020 SPACE, and *methodName*.
    4. Set *handler* to the result of invoking the [Get Trusted Type compliant string](#) algorithm with [TrustedScript](#), *global*, *handler*, *sink*, and "script".
  2. [Assert](#): *handler* is a string.
  3. Perform [EnsureCSPDoesNotBlockStringCompilation](#)(*realm*, « », *handler*, *handler*, timer, « », *handler*). If this throws an exception, catch it, [report](#)<sup>p1098</sup> it for *global*, and abort these steps.
  4. Let *settings object* be *global*'s [relevant settings object](#)<sup>p1083</sup>.
  5. Let *fetch options* be the [default script fetch options](#)<sup>p1086</sup>.
  6. Let *base URL* be *settings object*'s [API base URL](#)<sup>p1076</sup>.
  7. If *initiating script* is not null, then:
    1. Set *fetch options* to a [script fetch options](#)<sup>p1085</sup> whose [cryptographic nonce](#)<sup>p1086</sup> is *initiating script*'s [fetch options](#)<sup>p1085</sup>'s [cryptographic nonce](#)<sup>p1086</sup>, [integrity metadata](#)<sup>p1086</sup> is the empty string, [parser metadata](#)<sup>p1086</sup> is "not-parser-inserted", [credentials mode](#)<sup>p1086</sup> is *initiating script*'s [fetch options](#)<sup>p1085</sup>'s [credentials mode](#)<sup>p1086</sup>, [referrer policy](#)<sup>p1086</sup> is *initiating script*'s [fetch options](#)<sup>p1085</sup>'s [referrer policy](#)<sup>p1086</sup>, and [fetch priority](#)<sup>p1086</sup> is "auto".
    2. Set *base URL* to *initiating script*'s [base URL](#)<sup>p1085</sup>.

#### Note

*The effect of these steps ensures that the string compilation done by [setTimeout\(\)](#)<sup>p1162</sup> and [setInterval\(\)](#)<sup>p1162</sup> behaves equivalently to that done by [eval\(\)](#). That is, [module script](#)<sup>p1085</sup> fetches via [import\(\)](#) will behave the same in both contexts.*

8. Let *script* be the result of [creating a classic script](#)<sup>p1093</sup> given *handler*, *settings object*, *base URL*, and *fetch options*.
9. [Run the classic script](#)<sup>p1096</sup> *script*.
7. If *id* does not [exist](#) in *global*'s [map of setTimeout and setInterval IDs](#)<sup>p1162</sup>, then abort these steps.
8. If *global*'s [map of setTimeout and setInterval IDs](#)<sup>p1162</sup>[*id*] does not equal *uniqueHandle*, then abort these steps.

#### Note

*The ID might have been removed via the author code in *handler* calling [clearTimeout\(\)](#)<sup>p1162</sup> or [clearInterval\(\)](#)<sup>p1162</sup>. Checking that *uniqueHandle* isn't different accounts for the possibility of the ID, after having been cleared, being reused by a subsequent [setTimeout\(\)](#)<sup>p1162</sup> or [setInterval\(\)](#)<sup>p1162</sup> call.*

9. If *repeat* is true, then perform the [timer initialization steps](#)<sup>p1162</sup> again, given *global*, *handler*, *timeout*, *arguments*, true, and *id*.

10. Otherwise, [remove global's map of setTimeout and setInterval IDs](#)<sup>p1162</sup>[id].
10. Increment *nesting level* by one.
11. Set task's **timer nesting level** to *nesting level*.
12. Let *completionStep* be an algorithm step which [queues a global task](#)<sup>p1125</sup> on the **timer task source** given *global* to run *task*.
13. Set *uniqueHandle* to the result of [running steps after a timeout](#)<sup>p1164</sup> given *global*, "setTimeout/setInterval", *timeout*, *completionStep*.
14. [Set global's map of setTimeout and setInterval IDs](#)<sup>p1162</sup>[id] to *uniqueHandle*.
15. Return *id*.

#### Note

*Argument conversion as defined by Web IDL (for example, invoking `toString()` methods on objects passed as the first argument) happens in the algorithms defined in Web IDL, before this algorithm is invoked.*

#### Example

So for example, the following rather silly code will result in the log containing "ONE TWO ":

```
var log = '';
function logger(s) { log += s + ' '; }

setTimeout({ toString: function () {
  setTimeout("logger('ONE')", 100);
  return "logger('TWO')";
} }, 100);
```

#### Example

To run tasks of several milliseconds back to back without any delay, while still yielding back to the browser to avoid starving the user interface (and to avoid the browser killing the script for hogging the CPU), simply queue the next timer before performing work:

```
function doExpensiveWork() {
  var done = false;
  // ...
  // this part of the function takes up to five milliseconds
  // set done to true if we're done
  // ...
  return done;
}

function rescheduleWork() {
  var id = setTimeout(rescheduleWork, 0); // preschedule next iteration
  if (doExpensiveWork())
    clearTimeout(id); // clear the timeout if we don't need it
}

function scheduleWork() {
  setTimeout(rescheduleWork, 0);
}

scheduleWork(); // queues a task to do lots of work
```

Objects that implement the [WindowOrWorkerGlobalScope](#)<sup>p1148</sup> mixin have a **map of active timers**, which is an [ordered map](#), initially empty. Each [key](#) in this map is a [unique internal value](#)<sup>p96</sup> that represents a timer, and each [value](#) is a [DOMHighResTimeStamp](#), representing the expiry time for that timer.

To **run steps after a timeout**, given a [WindowOrWorkerGlobalScope](#)<sup>p1148</sup> *global*, a string *orderingIdentifier*, a number *milliseconds*,

and a set of steps *completionSteps*, perform the following steps. They return a [unique internal value](#)<sup>p96</sup>.

1. Let *timerKey* be a new [unique internal value](#)<sup>p96</sup>.
2. Let *startTime* be the [current high resolution time](#) given *global*.
3. Set *global*'s [map of active timers](#)<sup>p1164</sup>[*timerKey*] to *startTime* plus *milliseconds*.
4. Run the following steps [in parallel](#)<sup>p43</sup>:
  1. If *global* is a [Window](#)<sup>p922</sup> object, wait until *global*'s [associated Document](#)<sup>p923</sup> has been [fully active](#)<sup>p1003</sup> for a further *milliseconds* milliseconds (not necessarily consecutively).  
  
Otherwise, *global* is a [WorkerGlobalScope](#)<sup>p1228</sup> object; wait until *milliseconds* milliseconds have passed with the worker not suspended (not necessarily consecutively).
  2. Wait until any invocations of this algorithm that had the same *global* and *orderingIdentifier*, that started before this one, and whose *milliseconds* is less than or equal to this one's, have completed.
  3. Optionally, wait a further [implementation-defined](#) length of time.

#### Note

*This is intended to allow user agents to pad timeouts as needed to optimize the power usage of the device. For example, some processors have a low-power mode where the granularity of timers is reduced; on such platforms, user agents can slow timers down to fit this schedule instead of requiring the processor to use the more accurate mode with its associated higher power usage.*

4. Perform *completionSteps*.
  5. Remove *global*'s [map of active timers](#)<sup>p1164</sup>[*timerKey*].
5. Return *timerKey*.

#### Note

[Run steps after a timeout](#)<sup>p1164</sup> is meant to be used by other specifications that want to execute developer-supplied code after a developer-supplied timeout, in a similar manner to [setTimeout\(\)](#)<sup>p1162</sup>. (Note, however, it does not have the nesting and clamping behavior of [setTimeout\(\)](#)<sup>p1162</sup>.) Such specifications can choose an *orderingIdentifier* to ensure ordering within their specification's timeouts, while not constraining ordering with respect to other specification's timeouts.

## 8.7 Microtask queuing <sup>p1165</sup>

For web developers (non-normative)

```
self.queueMicrotaskp1165(callback)
```

[Queues](#)<sup>p1125</sup> a [microtask](#)<sup>p1124</sup> to run the given *callback*.

The **queueMicrotask(*callback*)** method must [queue a microtask](#)<sup>p1125</sup> to [invoke](#) *callback* with « » and "report".

The **queueMicrotask()**<sup>p1165</sup> method allows authors to schedule a callback on the [microtask queue](#)<sup>p1124</sup>. This allows their code to run once the [JavaScript execution context stack](#) is next empty, which happens once all currently executing synchronous JavaScript has run to completion. This doesn't yield control back to the [event loop](#)<sup>p1123</sup>, as would be the case when using, for example, [setTimeout\(\*f\*, 0\)](#)<sup>p1162</sup>.

Authors ought to be aware that scheduling a lot of microtasks has the same performance downsides as running a lot of synchronous code. Both will prevent the browser from doing its own work, such as rendering. In many cases, [requestAnimationFrame\(\)](#)<sup>p1187</sup> or [requestIdleCallback\(\)](#) is a better choice. In particular, if the goal is to run code before the next rendering cycle, that is the purpose of [requestAnimationFrame\(\)](#)<sup>p1187</sup>.

As can be seen from the following examples, the best way of thinking about **queueMicrotask()**<sup>p1165</sup> is as a mechanism for rearranging synchronous code, effectively placing the queued code immediately after the currently executing synchronous JavaScript has run to completion.

## Example

The most common reason for using [queueMicrotask\(\)](#) <sup>p1165</sup> is to create consistent ordering, even in the cases where information is available synchronously, without introducing undue delay.

For example, consider a custom element firing a `load` event, that also maintains an internal cache of previously-loaded data. A naïve implementation might look like:

```
MyElement.prototype.loadData = function (url) {
  if (this._cache[url]) {
    this._setData(this._cache[url]);
    this.dispatchEvent(new Event("load"));
  } else {
    fetch(url).then(res => res.arrayBuffer()).then(data => {
      this._cache[url] = data;
      this._setData(data);
      this.dispatchEvent(new Event("load"));
    });
  }
};
```

This naïve implementation is problematic, however, in that it causes its users to experience inconsistent behavior. For example, code such as

```
element.addEventListener("load", () => console.log("loaded"));
console.log("1");
element.loadData();
console.log("2");
```

will sometimes log "1, 2, loaded" (if the data needs to be fetched), and sometimes log "1, loaded, 2" (if the data is already cached). Similarly, after the call to `loadData()`, it will be inconsistent whether or not the data is set on the element.

To get a consistent ordering, [queueMicrotask\(\)](#) <sup>p1165</sup> can be used:

```
MyElement.prototype.loadData = function (url) {
  if (this._cache[url]) {
    queueMicrotask(() => {
      this._setData(this._cache[url]);
      this.dispatchEvent(new Event("load"));
    });
  } else {
    fetch(url).then(res => res.arrayBuffer()).then(data => {
      this._cache[url] = data;
      this._setData(data);
      this.dispatchEvent(new Event("load"));
    });
  }
};
```

By essentially rearranging the queued code to be after the [JavaScript execution context stack](#) empties, this ensures a consistent ordering and update of the element's state.

## Example

Another interesting use of [queueMicrotask\(\)](#) <sup>p1165</sup> is to allow uncoordinated "batching" of work by multiple callers. For example, consider a library function that wants to send data somewhere as soon as possible, but doesn't want to make multiple network requests if doing so is easily avoidable. One way to balance this would be like so:

```
const queuedToSend = [];

function sendData(data) {
  queuedToSend.push(data);
}
```

```

if (queuedToSend.length === 1) {
  queueMicrotask(() => {
    const stringToSend = JSON.stringify(queuedToSend);
    queuedToSend.length = 0;

    fetch("/endpoint", stringToSend);
  });
}
}

```

With this architecture, multiple subsequent calls to `sendData()` within the currently executing synchronous JavaScript will be batched together into one `fetch()` call, but with no intervening event loop tasks preempting the fetch (as would have happened with similar code that instead used `setTimeout()`<sup>p1162</sup>).

## 8.8 User prompts §<sup>p11</sup><sub>67</sub>

### 8.8.1 Simple dialogs §<sup>p11</sup><sub>67</sub>

For web developers (non-normative)

**`window.alert`<sup>p1167</sup>(*message*)**

Displays a modal alert with the given message, and waits for the user to dismiss it.

**`result = window.confirm`<sup>p1168</sup>(*message*)**

Displays a modal OK/Cancel prompt with the given message, waits for the user to dismiss it, and returns true if the user clicks OK and false if the user clicks Cancel.

**`result = window.prompt`<sup>p1168</sup>(*message* [, *default*])**

Displays a modal text control prompt with the given message, waits for the user to dismiss it, and returns the value that the user entered. If the user cancels the prompt, then returns null instead. If the second argument is present, then the given value is used as a default.

#### Note

Logic that depends on [tasks](#)<sup>p1124</sup> or [microtasks](#)<sup>p1124</sup>, such as [media elements](#)<sup>p414</sup> loading their [media data](#)<sup>p415</sup>, are stalled when these methods are invoked.

The `alert()` and `alert(message)` method steps are:

1. If we [cannot show simple dialogs](#)<sup>p1168</sup> for [this](#), then return.
2. If the method was invoked with no arguments, then let *message* be the empty string; otherwise, let *message* be the method's first argument.
3. Set *message* to the result of [normalizing newlines](#) given *message*.
4. Set *message* to the result of [optionally truncating](#)<sup>p1168</sup> *message*.
5. Let *userPromptHandler* be [WebDriver BiDi user prompt opened](#) with [this](#), "alert", and *message*.
6. If *userPromptHandler* is "none", then:
  1. Show *message* to the user, treating U+000A LF as a line break.
  2. Optionally, [pause](#)<sup>p1133</sup> while waiting for the user to acknowledge the message.
7. Invoke [WebDriver BiDi user prompt closed](#) with [this](#), "alert", and true.

#### Note

This method is defined using two overloads, instead of using an optional argument, for historical reasons. The practical impact of

*this is that* `alert(undefined)` *is treated as* `alert("undefined")`, *but* `alert()` *is treated as* `alert("")`.

The **confirm(message)** method steps are:

1. If we [cannot show simple dialogs](#)<sup>p1168</sup> for *this*, then return false.
2. Set *message* to the result of [normalizing newlines](#) given *message*.
3. Set *message* to the result of [optionally truncating](#)<sup>p1168</sup> *message*.
4. Show *message* to the user, treating U+000A LF as a line break, and ask the user to respond with a positive or negative response.
5. Let *userPromptHandler* be [WebDriver BiDi user prompt opened](#) with *this*, "confirm", and *message*.
6. Let *accepted* be false.
7. If *userPromptHandler* is "none", then:
  1. [Pause](#)<sup>p1133</sup> until the user responds either positively or negatively.
  2. If the user responded positively, then set *accepted* to true.
8. If *userPromptHandler* is "accept", then set *accepted* to true.
9. Invoke [WebDriver BiDi user prompt closed](#) with *this*, "confirm", and *accepted*.
10. Return *accepted*.

The **prompt(message, default)** method steps are:

1. If we [cannot show simple dialogs](#)<sup>p1168</sup> for *this*, then return null.
2. Set *message* to the result of [normalizing newlines](#) given *message*.
3. Set *message* to the result of [optionally truncating](#)<sup>p1168</sup> *message*.
4. Set *default* to the result of [optionally truncating](#)<sup>p1168</sup> *default*.
5. Show *message* to the user, treating U+000A LF as a line break, and ask the user to either respond with a string value or abort. The response must be defaulted to the value given by *default*.
6. Let *userPromptHandler* be [WebDriver BiDi user prompt opened](#) with *this*, "prompt", and *message*.
7. Let *result* be null.
8. If *userPromptHandler* is "none", then:
  1. [Pause](#)<sup>p1133</sup> while waiting for the user's response.
  2. If the user did not abort, then set *result* to the string that the user responded with.
9. Otherwise, if *userPromptHandler* is "accept", then set *result* to the empty string.
10. Invoke [WebDriver BiDi user prompt closed](#) with *this*, "prompt", false if *result* is null or true otherwise, and *result*.
11. Return *result*.

To **optionally truncate a simple dialog string** *s*, return either *s* itself or some string derived from *s* that is shorter. User agents should not provide UI for displaying the elided portion of *s*, as this makes it too easy for abusers to create dialogs of the form "Important security alert! Click 'Show More' for full details!".

#### Note

*For example, a user agent might want to only display the first 100 characters of a message. Or, a user agent might replace the middle of the string with "...". These types of modifications can be useful in limiting the abuse potential of unnaturally large, trustworthy-looking system dialogs.*

We **cannot show simple dialogs** for a [Window](#)<sup>p922</sup> window when the following algorithm returns true:

1. If the [active sandboxing flag set](#)<sup>p917</sup> of window's [associated Document](#)<sup>p923</sup> has the [sandboxed modals flag](#)<sup>p915</sup> set, then return true.
2. If window's [relevant settings object](#)<sup>p1083</sup>'s [origin](#)<sup>p1076</sup> and window's [relevant settings object](#)<sup>p1083</sup>'s [top-level origin](#)<sup>p1076</sup> are not [same origin-domain](#)<sup>p899</sup>, then return true.
3. If window's [relevant agent](#)<sup>p1073</sup>'s [event loop](#)<sup>p1123</sup>'s [termination nesting level](#)<sup>p1064</sup> is nonzero, then optionally return true.
4. Optionally, return true. (For example, the user agent might give the user the option to ignore all modal dialogs, and would thus abort at this step whenever the method was invoked.)
5. Return false.

## 8.8.2 Printing <sup>p1169</sup>

For web developers (non-normative)

**`window.print()`**<sup>p1169</sup> ()

Prompts the user to print the page.

The **`print()`** method steps are:

1. Let *document* be *this*'s [associated Document](#)<sup>p923</sup>.
2. If *document* is not [fully active](#)<sup>p1003</sup>, then return.
3. If *document*'s [unload counter](#)<sup>p1064</sup> is greater than 0, then return.
4. If *document* is [ready for post-load tasks](#)<sup>p1359</sup>, then run the [printing steps](#)<sup>p1169</sup> for *document*.
5. Otherwise, set *document*'s **print when loaded** flag.

User agents should also run the [printing steps](#)<sup>p1169</sup> whenever the user asks for the opportunity to [obtain a physical form](#)<sup>p1423</sup> (e.g. printed copy), or the representation of a physical form (e.g. PDF copy), of a document.

The **printing steps** for a [Document](#)<sup>p139</sup> *document* are:

1. The user agent may display a message to the user or return (or both).

### Example

For instance, a kiosk browser could silently ignore any invocations of the **`print()`**<sup>p1169</sup> method.

### Example

For instance, a browser on a mobile device could detect that there are no printers in the vicinity and display a message saying so before continuing to offer a "save to PDF" option.

2. If the [active sandboxing flag set](#)<sup>p917</sup> of *document* has the [sandboxed modals flag](#)<sup>p915</sup> set, then return.

### Note

*If the printing dialog is blocked by a [Document](#)<sup>p139</sup>'s sandbox, then neither the [beforeprint](#)<sup>p1471</sup> nor [afterprint](#)<sup>p1471</sup> events will be fired.*

3. The user agent must [fire an event](#) named [beforeprint](#)<sup>p1471</sup> at the [relevant global object](#)<sup>p1083</sup> of *document*, as well as any [child navigable](#)<sup>p992</sup> in it.

Firing in children only doesn't seem right here, and some tasks likely need to be queued. See [issue #5096](#).

### Example

The [beforeprint](#)<sup>p1471</sup> event can be used to annotate the printed copy, for instance adding the time at which the document was printed.

4. The user agent should offer the user the opportunity to [obtain a physical form](#)<sup>p1423</sup> (or the representation of a physical form)

of *document*. The user agent may wait for the user to either accept or decline before returning; if so, the user agent must [pause](#)<sup>p1133</sup> while the method is waiting. Even if the user agent doesn't wait at this point, the user agent must use the state of the relevant documents as they are at this point in the algorithm if and when it eventually creates the alternate form.

5. The user agent must [fire an event](#) named [afterprint](#)<sup>p1471</sup> at the [relevant global object](#)<sup>p1083</sup> of *document*, as well as any [child navigables](#)<sup>p992</sup> in it.

Firing in children only doesn't seem right here, and some tasks likely need to be queued. See [issue #5096](#).

#### Example

The [afterprint](#)<sup>p1471</sup> event can be used to revert annotations added in the earlier event, as well as showing post-printing UI. For instance, if a page is walking the user through the steps of applying for a home loan, the script could automatically advance to the next step after having printed a form or other.

## 8.9 System state and capabilities § p1170

### 8.9.1 The [Navigator](#)<sup>p1170</sup> object § p1170

Instances of [Navigator](#)<sup>p1170</sup> represent the identity and state of the user agent (the client). It has also been used as a generic global under which various APIs are located, but this is not precedent to build upon. Instead use the [WindowOrWorkerGlobalScope](#)<sup>p1148</sup> mixin or equivalent.

```
IDL [Exposed=Window]
interface Navigator {
    // objects implementing this interface also implement the interfaces given below
};
Navigator includes NavigatorID;
Navigator includes NavigatorLanguage;
Navigator includes NavigatorOnLine;
Navigator includes NavigatorContentUtils;
Navigator includes NavigatorCookies;
Navigator includes NavigatorPlugins;
Navigator includes NavigatorConcurrentHardware;
```

**Note** These interface mixins are defined separately so that [WorkerNavigator](#)<sup>p1240</sup> can reuse parts of the [Navigator](#)<sup>p1170</sup> interface.

Each [Window](#)<sup>p922</sup> has an **associated Navigator**, which is a [Navigator](#)<sup>p1170</sup> object. Upon creation of the [Window](#)<sup>p922</sup> object, its **associated Navigator**<sup>p1170</sup> must be set to a [new Navigator](#)<sup>p1170</sup> object created in the [Window](#)<sup>p922</sup> object's [relevant realm](#)<sup>p1083</sup>.

The **navigator** and **clientInformation** getter steps are to return [this](#)'s [associated Navigator](#)<sup>p1170</sup>.

#### 8.9.1.1 Client identification § p1170

```
IDL interface mixin NavigatorID {
    readonly attribute DOMString appCodeName; // constant "Mozilla"
    readonly attribute DOMString appName; // constant "Netscape"
    readonly attribute DOMString appVersion;
    readonly attribute DOMString platform;
    readonly attribute DOMString product; // constant "Gecko"
    [Exposed=Window] readonly attribute DOMString productSub;
    readonly attribute DOMString userAgent;
    [Exposed=Window] readonly attribute DOMString vendor;
    [Exposed=Window] readonly attribute DOMString vendorSub; // constant ""
};
```

In certain cases, despite the best efforts of the entire industry, web browsers have bugs and limitations that web authors are forced to work around.

This section defines a collection of attributes that can be used to determine, from script, the kind of user agent in use, in order to work around these issues.

The user agent has a **navigator compatibility mode**, which is either *Chrome*, *Gecko*, or *WebKit*.

#### Note

The [navigator compatibility mode](#)<sup>p1171</sup> constrains the [NavigatorID](#)<sup>p1170</sup> mixin to the combinations of attribute values and presence of [taintEnabled\(\)](#)<sup>p1172</sup> and [oscpu](#)<sup>p1172</sup> that are known to be compatible with existing web content.

Client detection should always be limited to detecting known current versions; future versions and unknown versions should always be assumed to be fully compliant.

#### For web developers (non-normative)

**[self.navigator](#)**<sup>p1170</sup>.**[appCodeName](#)**<sup>p1171</sup>

Returns the string "Mozilla".

**[self.navigator](#)**<sup>p1170</sup>.**[appName](#)**<sup>p1171</sup>

Returns the string "Netscape".

**[self.navigator](#)**<sup>p1170</sup>.**[appVersion](#)**<sup>p1171</sup>

Returns the version of the browser.

**[self.navigator](#)**<sup>p1170</sup>.**[platform](#)**<sup>p1172</sup>

Returns the name of the platform.

**[self.navigator](#)**<sup>p1170</sup>.**[product](#)**<sup>p1172</sup>

Returns the string "Gecko".

**[window.navigator](#)**<sup>p1170</sup>.**[productSub](#)**<sup>p1172</sup>

Returns either the string "20030107", or the string "20100101".

**[self.navigator](#)**<sup>p1170</sup>.**[userAgent](#)**<sup>p1172</sup>

Returns the complete `User-Agent` header.

**[window.navigator](#)**<sup>p1170</sup>.**[vendor](#)**<sup>p1172</sup>

Returns either the empty string, the string "Apple Computer, Inc.", or the string "Google Inc.".

**[window.navigator](#)**<sup>p1170</sup>.**[vendorSub](#)**<sup>p1172</sup>

Returns the empty string.

#### **appCodeName**

Must return the string "Mozilla".

#### **appName**

Must return the string "Netscape".

#### **appVersion**

Must return the appropriate string that starts with "5.0 (" , as follows:

Let *trail* be the substring of [default `User-Agent` value](#) that follows the "Mozilla/" prefix.

↪ If the [navigator compatibility mode](#)<sup>p1171</sup> is *Chrome* or *WebKit*  
Return *trail*.

↪ If the [navigator compatibility mode](#)<sup>p1171</sup> is *Gecko*  
If *trail* starts with "5.0 (Windows)", then return "5.0 (Windows)".

Otherwise, return the prefix of *trail* up to but not including the first U+003B (;), concatenated with the character U+0029 RIGHT PARENTHESIS. For example, "5.0 (Macintosh)", "5.0 (Android 10)", or "5.0 (X11)".

## platform

Must return a string representing the platform on which the browser is executing (e.g. "MacIntel", "Win32", "Linux x86\_64", "Linux armv81") or, for privacy and compatibility, a string that is commonly returned on another platform.

## product

Must return the string "Gecko".

## productSub

Must return the appropriate string from the following list:

- ↪ If the [navigator compatibility mode](#)<sup>p1171</sup> is **Chrome** or **WebKit**  
The string "20030107".
- ↪ If the [navigator compatibility mode](#)<sup>p1171</sup> is **Gecko**  
The string "20100101".

## userAgent

Must return the [default `User-Agent` value](#).

## vendor

Must return the appropriate string from the following list:

- ↪ If the [navigator compatibility mode](#)<sup>p1171</sup> is **Chrome**  
The string "Google Inc.".
- ↪ If the [navigator compatibility mode](#)<sup>p1171</sup> is **Gecko**  
The empty string.
- ↪ If the [navigator compatibility mode](#)<sup>p1171</sup> is **WebKit**  
The string "Apple Computer, Inc.".

## vendorSub

Must return the empty string.

If the [navigator compatibility mode](#)<sup>p1171</sup> is **Gecko**, then the user agent must also support the following partial interface:

```
IDL partial interface mixin NavigatorID {  
  [Exposed=Window] boolean taintEnabled(); // constant false  
  [Exposed=Window] readonly attribute DOMString oscpu;  
};
```

The **taintEnabled()** method must return false.

The **oscpu** attribute's getter must return either the empty string or a string representing the platform on which the browser is executing, e.g. "Windows NT 10.0; Win64; x64", "Linux x86\_64".

## ⚠Warning!

**Any information in this API that varies from user to user can be used to profile the user. In fact, if enough such information is available, a user can actually be uniquely identified. For this reason, user agent implementers are strongly urged to include as little information in this API as possible.**

## 8.9.1.2 Language preferences <sup>§p11</sup><sub>72</sub>

```
IDL interface mixin NavigatorLanguage {  
  readonly attribute DOMString language;  
  readonly attribute FrozenArray<DOMString> languages;  
};
```

For web developers (non-normative)

**`self.navigatorp1170.languagep1173`**

Returns a language tag representing the user's preferred language.

**`self.navigatorp1170.languagesp1173`**

Returns an array of language tags representing the user's preferred languages, with the most preferred language first.

The most preferred language is the one returned by `navigator.languagep1173`.

#### Note

A `languagechangep1471` event is fired at the `Windowp922` or `WorkerGlobalScopep1228` object when the user agent's understanding of what the user's preferred languages are changes.

### Language

Must return a valid BCP 47 language tag representing either a [plausible language<sup>p1173</sup>](#) or the user's most preferred language.

[\[BCP47\]<sup>p1475</sup>](#)

### Languages

Must return a [frozen array](#) of valid BCP 47 language tags representing either one or more [plausible languages<sup>p1173</sup>](#), or the user's preferred languages, ordered by preference with the most preferred language first. The same object must be returned until the user agent needs to return different values, or values in a different order. [\[BCP47\]<sup>p1475</sup>](#)

Whenever the user agent needs to make the `navigator.languagesp1173` attribute of a `Windowp922` or `WorkerGlobalScopep1228` object *global* return a new set of language tags, the user agent must [queue a global task<sup>p1125</sup>](#) on the [DOM manipulation task source<sup>p1134</sup>](#) given *global* to [fire an event](#) named `languagechangep1471` at *global*, and wait until that task begins to be executed before actually returning a new value.

To determine a **plausible language**, the user agent should bear in mind the following:

- Any information in this API that varies from user to user can be used to profile or identify the user.
- If the user is not using a service that obfuscates the user's point of origin (e.g. the Tor anonymity network), then the value that is least likely to distinguish the user from other users with similar origins (e.g. from the same IP address block) is the language used by the majority of such users. [\[TOR\]<sup>p1482</sup>](#)
- If the user is using an anonymizing service, then the value "en-US" is suggested; if all users of the service use that same value, that reduces the possibility of distinguishing the users from each other.

To avoid introducing any more fingerprinting vectors, user agents should use the same list for the APIs defined in this function as for the HTTP ``Accept-Language`` header.

#### 8.9.1.3 Browser state <sup>p1173</sup>

```
IDL interface mixin NavigatorOnLine {  
  readonly attribute boolean online;  
};
```

#### For web developers (non-normative)

**`self.navigatorp1170.onlinep1173`**

Returns false if the user agent is definitely offline (disconnected from the network). Returns true if the user agent might be online.

The events `onlinep1472` and `offlinep1472` are fired when the value of this attribute changes.

The `online` attribute must return false if the user agent will not contact the network when the user follows links or when a script requests a remote page (or knows that such an attempt would fail), and must return true otherwise.

When the value that would be returned by the `navigator.onlinep1173` attribute of a `Windowp922` or `WorkerGlobalScopep1228` *global* changes from true to false, the user agent must [queue a global task<sup>p1125</sup>](#) on the [networking task source<sup>p1134</sup>](#) given *global* to [fire an event](#) named `offlinep1472` at *global*.

On the other hand, when the value that would be returned by the [navigator.onLine](#)<sup>p1173</sup> attribute of a [Window](#)<sup>p922</sup> or [WorkerGlobalScope](#)<sup>p1228</sup> *global* changes from false to true, the user agent must [queue a global task](#)<sup>p1125</sup> on the [networking task source](#)<sup>p1134</sup> given *global* to [fire an event](#) named [online](#)<sup>p1472</sup> at the [Window](#)<sup>p922</sup> or [WorkerGlobalScope](#)<sup>p1228</sup> object.

#### Note

*This attribute is inherently unreliable. A computer can be connected to a network without having Internet access.*

#### Example

In this example, an indicator is updated as the browser goes online and offline.

```
<!DOCTYPE HTML>
<html lang="en">
<head>
  <title>Online status</title>
  <script>
    function updateIndicator() {
      document.getElementById('indicator').textContent = navigator.onLine ? 'online' : 'offline';
    }
  </script>
</head>
<body onload="updateIndicator()" ononline="updateIndicator()" onoffline="updateIndicator()">
  <p>The network is: <span id="indicator">(state unknown)</span>
</body>
</html>
```

### 8.9.1.4 Custom scheme handlers: the [registerProtocolHandler\(\)](#)<sup>p1174</sup> method §<sup>p11</sup>74

MDN

```
IDL interface mixin NavigatorContentUtils {
  [SecureContext] undefined registerProtocolHandler(DOMString scheme, USVString url);
  [SecureContext] undefined unregisterProtocolHandler(DOMString scheme, USVString url);
};
```

#### For web developers (non-normative)

**[window.navigator](#)<sup>p1170</sup>.[registerProtocolHandler](#)<sup>p1174</sup>(*scheme*, *url*)**

Registers a handler for *scheme* at *url*. For example, an online telephone messaging service could register itself as a handler of the [sms:](#) scheme, so that if the user clicks on such a link, they are given the opportunity to use that web site. [\[SMS\]](#)<sup>p1482</sup>

The string "%s" in *url* is used as a placeholder for where to put the URL of the content to be handled.

Throws a ["SecurityError" DOMException](#) if the user agent blocks the registration (this might happen if trying to register as a handler for "http", for instance).

Throws a ["SyntaxError" DOMException](#) if the "%s" string is missing in *url*.

**[window.navigator](#)<sup>p1170</sup>.[unregisterProtocolHandler](#)<sup>p1175</sup>(*scheme*, *url*)**

Unregisters the handler given by the arguments.

Throws a ["SecurityError" DOMException](#) if the user agent blocks the deregistration (this might happen if with invalid schemes, for instance).

Throws a ["SyntaxError" DOMException](#) if the "%s" string is missing in *url*.

The [registerProtocolHandler\(\*scheme\*, \*url\*\)](#) method steps are:

1. Let (*normalizedScheme*, *normalizedURLString*) be the result of running [normalize protocol handler parameters](#)<sup>p1175</sup> with *scheme*, *url*, and [this's relevant settings object](#)<sup>p1083</sup>.
2. [In parallel](#)<sup>p43</sup>: **register a protocol handler** for *normalizedScheme* and *normalizedURLString*. User agents may, within the constraints described, do whatever they like. A user agent could, for instance, prompt the user and offer the user the opportunity to add the site to a shortlist of handlers, or make the handlers their default, or cancel the request. User agents could also silently collect the information, providing it only when relevant to the user.

User agents should keep track of which sites have registered handlers (even if the user has declined such registrations) so that the user is not repeatedly prompted with the same request.

If the `registerProtocolHandler()` [automation mode](#)<sup>p1177</sup> of this's [relevant global object](#)<sup>p1083</sup>'s [associated Document](#)<sup>p923</sup> is not `"none"`, the user agent should first verify that it is in an automation context (see [WebDriver's security considerations](#)). The user agent should then bypass the above communication of information and gathering of user consent, and instead do the following based on the value of the `registerProtocolHandler()` [automation mode](#)<sup>p1177</sup>:

#### "autoAccept"

Act as if the user has seen the registration details and accepted the request.

#### "autoReject"

Act as if the user has seen the registration details and rejected the request.

When the **user agent uses this handler** for a [URL](#) *inputURL*:

1. [Assert](#): *inputURL*'s [scheme](#) is [normalizedScheme](#).
2. [Set the username](#) given *inputURL* and the empty string.
3. [Set the password](#) given *inputURL* and the empty string.
4. Let *inputURLString* be the [serialization](#) of *inputURL*.
5. Let *encodedURL* be the result of running [UTF-8 percent-encode](#) on *inputURLString* using the [component percent-encode set](#).
6. Let *handlerURLString* be [normalizedURLString](#).
7. Replace the first instance of `"%s"` in *handlerURLString* with *encodedURL*.
8. Let *resultURL* be the result of [parsing](#) *handlerURLString*.
9. [Navigate](#)<sup>p1014</sup> an appropriate [navigable](#)<sup>p989</sup> to *resultURL*.

#### Example

If the user had visited a site at `https://example.com/` that made the following call:

```
navigator.registerProtocolHandler('web+soup', 'soup?url=%s')
```

...and then, much later, while visiting `https://www.example.net/`, clicked on a link such as:

```
<a href="web+soup:chicken-kiwi">Download our Chicken Kiwi soup!</a>
```

...then the UA might navigate to the following URL:

```
https://example.com/soup?url=web+soup:chicken-k%C3%AFwi
```

This site could then do whatever it is that it does with soup (synthesize it and ship it to the user, or whatever).

This does not define when the handler is used. To some extent, the [processing model for navigating across documents](#)<sup>p1014</sup> defines some cases where it is relevant, but in general user agents may use this information wherever they would otherwise consider handing schemes to native plugins or helper applications.

The `unregisterProtocolHandler(scheme, url)` method steps are:

1. Let (*normalizedScheme*, *normalizedURLString*) be the result of running [normalize protocol handler parameters](#)<sup>p1175</sup> with *scheme*, *url*, and this's [relevant settings object](#)<sup>p1083</sup>.
2. [In parallel](#)<sup>p43</sup>: unregister the handler described by *normalizedScheme* and *normalizedURLString*.

To **normalize protocol handler parameters**, given a string *scheme*, a string *url*, and an [environment settings object](#)<sup>p1076</sup> *environment*, run these steps:

1. Set *scheme* to *scheme*, [converted to ASCII lowercase](#).

2. If *scheme* is neither a [safelisted scheme](#)<sup>p1176</sup> nor a string starting with "web+" followed by one or more [ASCII lower alphas](#), then throw a ["SecurityError" DOMException](#).

**Note**

*This means that including a colon in scheme (as in "mailto:") will throw.*

The following schemes are the **safelisted schemes**:

- bitcoin
- ftp
- ftps
- geo
- im
- irc
- ircs
- magnet
- mailto
- matrix
- mms
- news
- nntp
- openpgp4fpr
- sftp
- sip
- sms
- smsto
- ssh
- tel
- urn
- webcal
- wtai
- xmpp

**Note**

*This list can be changed. If there are schemes that ought to be added, please send feedback.*

3. If *url* does not contain "%s", then throw a ["SyntaxError" DOMException](#).
4. Let *urlRecord* be the result of [encoding-parsing a URL](#)<sup>p97</sup> given *url*, relative to *environment*.
5. If *urlRecord* is failure, then throw a ["SyntaxError" DOMException](#).

**Note**

*This is forcibly the case if the %s placeholder is in the host or port of the URL.*

6. If *urlRecord*'s [scheme](#) is not an [HTTP\(S\) scheme](#) or *urlRecord*'s [origin](#) is not [same origin](#)<sup>p899</sup> with *environment*'s [origin](#)<sup>p1076</sup>, then throw a ["SecurityError" DOMException](#).
7. [Assert](#): the result of [Is url potentially trustworthy?](#) given *urlRecord* is "Potentially Trustworthy".

**Note**

*Because [normalize protocol handler parameters](#)<sup>p1175</sup> is run within a [secure context](#)<sup>p1084</sup>, this is implied by the [same origin](#)<sup>p899</sup> condition.*

8. Return (*scheme*, *urlRecord*).

**Note**

*The [serialization](#) of *urlRecord* will by definition not be a [valid URL string](#) as it includes the string "%s" which is not a valid component in a URL.*

#### 8.9.1.4.1 Security and privacy <sup>§<sup>p11</sup><sub>76</sub></sup>

Custom scheme handlers can introduce a number of concerns, in particular privacy concerns.

**Hijacking all web usage.** User agents should not allow schemes that are key to its normal operation, such as an [HTTP\(S\) scheme](#), to be rerouted through third-party sites. This would allow a user's activities to be trivially tracked, and would allow user information, even in secure connections, to be collected.

**Hijacking defaults.** User agents are strongly urged to not automatically change any defaults, as this could lead the user to send data to remote hosts that the user is not expecting. New handlers registering themselves should never automatically cause those sites to be used.

**Registration spamming.** User agents should consider the possibility that a site will attempt to register a large number of handlers, possibly from multiple domains (e.g., by redirecting through a series of pages each on a different domain, and each registering a handler for `web+spam:` — analogous practices abusing other web browser features have been used by pornography web sites for many years). User agents should gracefully handle such hostile attempts, protecting the user.

**Hostile handler metadata.** User agents should protect against typical attacks against strings embedded in their interface, for example ensuring that markup or escape characters in such strings are not executed, that null bytes are properly handled, that over-long strings do not cause crashes or buffer overruns, and so forth.

**Leaking private data.** Web page authors may reference a custom scheme handler using URL data considered private. They might do so with the expectation that the user's choice of handler points to a page inside the organization, ensuring that sensitive data will not be exposed to third parties. However, a user may have registered a handler pointing to an external site, resulting in a data leak to that third party. Implementers might wish to consider allowing administrators to disable custom handlers on certain subdomains, content types, or schemes.

**Interface interference.** User agents should be prepared to handle intentionally long arguments to the methods. For example, if the user interface exposed consists of an "accept" button and a "deny" button, with the "accept" binding containing the name of the handler, it's important that a long name not cause the "deny" button to be pushed off the screen.

8.9.1.4.2 User agent automation §<sup>p11</sup><sub>77</sub>

Each `Document`<sup>p130</sup> has a `registerProtocolHandler()` **automation mode**. It defaults to "`none`"<sup>p1175</sup>, but it also can be either "`autoAccept`"<sup>p1175</sup> or "`autoReject`"<sup>p1175</sup>.

For the purposes of user agent automation and website testing, this standard defines **Set RPH Registration Mode** WebDriver [extension command](#). It instructs the user agent to place a `Document`<sup>p130</sup> into a mode where it will automatically simulate a user either accepting or rejecting and registration confirmation prompt dialog.

HTTP Method	URI Template
POST	/session/{session id}/custom-handlers/set-mode

The [remote end steps](#) are:

1. If *parameters* is not a JSON Object, return a [WebDriver error](#) with [WebDriver error code invalid argument](#).
2. Let *mode* be the result of [getting a property](#) named "mode" from *parameters*.
3. If *mode* is not "`autoAccept`"<sup>p1175</sup>, "`autoReject`"<sup>p1175</sup>, or "`none`"<sup>p1175</sup>, return a [WebDriver error](#) with [WebDriver error code invalid argument](#).
4. Let *document* be the [current browsing context](#)'s [active document](#)<sup>p998</sup>.
5. Set *document*'s `registerProtocolHandler()` [automation mode](#)<sup>p1177</sup> to *mode*.
6. Return [success](#) with data null.

8.9.1.5 Cookies §<sup>p11</sup><sub>77</sub>

```
IDL interface mixin NavigatorCookies {
  readonly attribute boolean cookieEnabled;
};
```

For web developers (non-normative)

`window.navigator`<sup>p1170</sup>.`cookieEnabled`<sup>p1178</sup>

Returns false if setting a cookie will be ignored, and true otherwise.

The **cookieEnabled** attribute must return true if the user agent attempts to handle cookies according to *HTTP State Management Mechanism*, and false if it ignores cookie change requests. [\[COOKIES\]](#)<sup>p1476</sup>

#### 8.9.1.6 PDF viewing support <sup>p1178</sup>

For web developers (non-normative)

**[window.navigator](#)**<sup>p1170</sup>.**[pdfViewerEnabled](#)**<sup>p1179</sup>

Returns true if the user agent supports inline viewing of PDF files when [navigating](#)<sup>p1014</sup> to them, or false otherwise. In the latter case, PDF files will be handled by [external software](#)<sup>p1024</sup>.

```
IDL interface mixin NavigatorPlugins {
    [SameObject] readonly attribute PluginArray plugins;
    [SameObject] readonly attribute MimeTypeArray mimeTypes;
    boolean javaEnabled();
    readonly attribute boolean pdfViewerEnabled;
};

[Exposed=Window,
 LegacyUnenumerableNamedProperties]
interface PluginArray {
    undefined refresh();
    readonly attribute unsigned long length;
    getter Plugin? item(unsigned long index);
    getter Plugin? namedItem(DOMString name);
};

[Exposed=Window,
 LegacyUnenumerableNamedProperties]
interface MimeTypeArray {
    readonly attribute unsigned long length;
    getter MimeType? item(unsigned long index);
    getter MimeType? namedItem(DOMString name);
};

[Exposed=Window,
 LegacyUnenumerableNamedProperties]
interface Plugin {
    readonly attribute DOMString name;
    readonly attribute DOMString description;
    readonly attribute DOMString filename;
    readonly attribute unsigned long length;
    getter MimeType? item(unsigned long index);
    getter MimeType? namedItem(DOMString name);
};

[Exposed=Window]
interface MimeType {
    readonly attribute DOMString type;
    readonly attribute DOMString description;
    readonly attribute DOMString suffixes;
    readonly attribute Plugin enabledPlugin;
};
```

Although these days detecting PDF viewer support can be done via [navigator.pdfViewerEnabled](#)<sup>p1179</sup>, for historical reasons, there are a number of complex and intertwined interfaces that provide the same capability, which legacy code relies on. This section specifies both the simple modern variant and the complicated historical one.

Each user agent has a **PDF viewer supported** boolean, whose value is [implementation-defined](#) (and might vary according to user preferences).

## Note

This value also impacts the [navigation<sup>p1014</sup>](#) processing model.

Each [Window<sup>p922</sup>](#) object has a **PDF viewer plugin objects** list. If the user agent's [PDF viewer supported<sup>p1178</sup>](#) is false, then it is the empty list. Otherwise, it is a list containing five [Plugin<sup>p1178</sup>](#) objects, whose [names<sup>p1180</sup>](#) are, respectively:

0. "PDF Viewer"
1. "Chrome PDF Viewer"
2. "Chromium PDF Viewer"
3. "Microsoft Edge PDF Viewer"
4. "WebKit built-in PDF"

The values of the above list form the **PDF viewer plugin names** list.

## Note

These names were chosen based on evidence of what websites historically search for, and thus what is necessary for user agents to expose in order to maintain compatibility with existing content. They are ordered alphabetically. The "PDF Viewer" name was then inserted in the 0th position so that the [enabledPlugin<sup>p1180</sup>](#) getter could point to a generic plugin name.

Each [Window<sup>p922</sup>](#) object has a **PDF viewer mime type objects** list. If the user agent's [PDF viewer supported<sup>p1178</sup>](#) is false, then it is the empty list. Otherwise, it is a list containing two [MimeType<sup>p1178</sup>](#) objects, whose [types<sup>p1180</sup>](#) are, respectively:

0. "application/pdf"
1. "text/pdf"

The values of the above list form the **PDF viewer mime types** list.

Each [NavigatorPlugins<sup>p1178</sup>](#) object has a **plugins array**, which is a new [PluginArray<sup>p1178</sup>](#), and a **mime types array**, which is a new [MimeTypeArray<sup>p1178</sup>](#).

The [NavigatorPlugins<sup>p1178</sup>](#) mixin's **plugins** getter steps are to return [this's plugins array<sup>p1179</sup>](#).

The [NavigatorPlugins<sup>p1178</sup>](#) mixin's **mimeTypes** getter steps are to return [this's mime types array<sup>p1179</sup>](#).

The [NavigatorPlugins<sup>p1178</sup>](#) mixin's **javaEnabled()** method steps are to return false.

The [NavigatorPlugins<sup>p1178</sup>](#) mixin's **pdfViewerEnabled** getter steps are to return the user agent's [PDF viewer supported<sup>p1178</sup>](#).

The [PluginArray<sup>p1178</sup>](#) interface [supports named properties](#). If the user agent's [PDF viewer supported<sup>p1178</sup>](#) is true, then they are the [PDF viewer plugin names<sup>p1179</sup>](#). Otherwise, they are the empty list.

The [PluginArray<sup>p1178</sup>](#) interface's **namedItem(name)** method steps are:

1. For each [Plugin<sup>p1178</sup>](#) plugin of [this's relevant global object<sup>p1083</sup>](#)'s [PDF viewer plugin objects<sup>p1179</sup>](#): if plugin's [name<sup>p1180</sup>](#) is name, then return plugin.
2. Return null.

The [PluginArray<sup>p1178</sup>](#) interface [supports indexed properties](#). The [supported property indices](#) are the [indices](#) of [this's relevant global object<sup>p1083</sup>](#)'s [PDF viewer plugin objects<sup>p1179</sup>](#).

The [PluginArray<sup>p1178</sup>](#) interface's **item(index)** method steps are:

1. Let *plugins* be [this's relevant global object<sup>p1083</sup>](#)'s [PDF viewer plugin objects<sup>p1179</sup>](#).
2. If *index* < *plugins*'s [size](#), then return *plugins*[*index*].
3. Return null.

The [PluginArray<sup>p1178</sup>](#) interface's **length** getter steps are to return [this's relevant global object<sup>p1083</sup>](#)'s [PDF viewer plugin objects<sup>p1179</sup>](#)'s [size](#).

The [PluginArray<sup>p1178</sup>](#) interface's **refresh()** method steps are to do nothing.

The [MimeTypeArray<sup>p1178</sup>](#) interface [supports named properties](#). If the user agent's [PDF viewer supported<sup>p1178</sup>](#) is true, then they are the [PDF viewer mime types<sup>p1179</sup>](#). Otherwise, they are the empty list.

The [MimeTypeArray<sup>p1178</sup>](#) interface's **namedItem(name)** method steps are:

1. For each [MimeType<sup>p1178</sup>](#) *contentType* of [this's relevant global object<sup>p1083</sup>](#)'s [PDF viewer mime type objects<sup>p1179</sup>](#): if *contentType*'s [type<sup>p1180</sup>](#) is *name*, then return *contentType*.
2. Return null.

The [MimeTypeArray<sup>p1178</sup>](#) interface [supports indexed properties](#). The [supported property indices](#) are the [indices](#) of [this's relevant global object<sup>p1083</sup>](#)'s [PDF viewer mime type objects<sup>p1179</sup>](#).

The [MimeTypeArray<sup>p1178</sup>](#) interface's **item(index)** method steps are:

1. Let *mimeTypes* be [this's relevant global object<sup>p1083</sup>](#)'s [PDF viewer mime type objects<sup>p1179</sup>](#).
2. If *index* < *mimeTypes*'s [size](#), then return *mimeTypes*[*index*].
3. Return null.

The [MimeTypeArray<sup>p1178</sup>](#) interface's **length** getter steps are to return [this's relevant global object<sup>p1083</sup>](#)'s [PDF viewer mime type objects<sup>p1179</sup>](#)'s [size](#).

Each [Plugin<sup>p1178</sup>](#) object has a **name**, which is set when the object is created.

The [Plugin<sup>p1178</sup>](#) interface's **name** getter steps are to return [this's name<sup>p1180</sup>](#).

The [Plugin<sup>p1178</sup>](#) interface's **description** getter steps are to return "Portable Document Format".

The [Plugin<sup>p1178</sup>](#) interface's **filename** getter steps are to return "internal-pdf-viewer".

The [Plugin<sup>p1178</sup>](#) interface [supports named properties](#). If the user agent's [PDF viewer supported<sup>p1178</sup>](#) is true, then they are the [PDF viewer mime types<sup>p1179</sup>](#). Otherwise, they are the empty list.

The [Plugin<sup>p1178</sup>](#) interface's **namedItem(name)** method steps are:

1. For each [MimeType<sup>p1178</sup>](#) *contentType* of [this's relevant global object<sup>p1083</sup>](#)'s [PDF viewer mime type objects<sup>p1179</sup>](#): if *contentType*'s [type<sup>p1180</sup>](#) is *name*, then return *contentType*.
2. Return null.

The [Plugin<sup>p1178</sup>](#) interface [supports indexed properties](#). The [supported property indices](#) are the [indices](#) of [this's relevant global object<sup>p1083</sup>](#)'s [PDF viewer mime type objects<sup>p1179</sup>](#).

The [Plugin<sup>p1178</sup>](#) interface's **item(index)** method steps are:

1. Let *mimeTypes* be [this's relevant global object<sup>p1083</sup>](#)'s [PDF viewer mime type objects<sup>p1179</sup>](#).
2. If *index* < *mimeTypes*'s [size](#), then return *mimeTypes*[*index*].
3. Return null.

The [Plugin<sup>p1178</sup>](#) interface's **length** getter steps are to return [this's relevant global object<sup>p1083</sup>](#)'s [PDF viewer mime type objects<sup>p1179</sup>](#)'s [size](#).

Each [MimeType<sup>p1178</sup>](#) object has a **type**, which is set when the object is created.

The [MimeType<sup>p1178</sup>](#) interface's **type** getter steps are to return [this's type<sup>p1180</sup>](#).

The [MimeType<sup>p1178</sup>](#) interface's **description** getter steps are to return "Portable Document Format".

The [MimeType<sup>p1178</sup>](#) interface's **suffixes** getter steps are to return "pdf".

The [MimeType<sup>p1178</sup>](#) interface's **enabledPlugin** getter steps are to return [this's relevant global object<sup>p1083</sup>](#)'s [PDF viewer plugin](#)

[objects](#)<sup>p1179</sup>[0] (i.e., the generic "PDF Viewer" one).

## 8.10 Images <sup>p1181</sup>

```
IDL [Exposed=(Window,Worker), Serializable, Transferable]
interface ImageBitmap {
    readonly attribute unsigned long width;
    readonly attribute unsigned long height;
    undefined close();
};

typedef (CanvasImageSource or
        Blob or
        ImageData) ImageBitmapSource;

enum ImageOrientation { "from-image", "flipY" };
enum PremultiplyAlpha { "none", "premultiply", "default" };
enum ColorSpaceConversion { "none", "default" };
enum ResizeQuality { "pixelated", "low", "medium", "high" };

dictionary ImageBitmapOptions {
    ImageOrientation imageOrientation = "from-image";
    PremultiplyAlpha premultiplyAlpha = "default";
    ColorSpaceConversion colorSpaceConversion = "default";
    [EnforceRange] unsigned long resizeWidth;
    [EnforceRange] unsigned long resizeHeight;
    ResizeQuality resizeQuality = "low";
};
```

An [ImageBitmap](#)<sup>p1181</sup> object represents a bitmap image that can be painted to a canvas without undue latency.

### Note

*The exact judgement of what is undue latency of this is left up to the implementer, but in general if making use of the bitmap requires network I/O, or even local disk I/O, then the latency is probably undue; whereas if it only requires a blocking read from a GPU or system RAM, the latency is probably acceptable.*

### For web developers (non-normative)

```
promise = self.createImageBitmapp1182(image [, options ])
```

```
promise = self.createImageBitmapp1182(image, sx, sy, sw, sh [, options ])
```

Takes *image*, which can be an [img](#)<sup>p346</sup> element, an [SVG image](#) element, a [video](#)<sup>p406</sup> element, a [canvas](#)<sup>p677</sup> element, a [Blob](#) object, an [ImageData](#)<sup>p686</sup> object, or another [ImageBitmap](#)<sup>p1181</sup> object, and returns a promise that is resolved when a new [ImageBitmap](#)<sup>p1181</sup> is created.

If no [ImageBitmap](#)<sup>p1181</sup> object can be constructed, for example because the provided *image* data is not actually an image, then the promise is rejected instead.

If *sx*, *sy*, *sw*, and *sh* arguments are provided, the source image is cropped to the given pixels, with any pixels missing in the original replaced by [transparent black](#). These coordinates are in the source image's pixel coordinate space, *not* in [CSS pixels](#).

If *options* is provided, the [ImageBitmap](#)<sup>p1181</sup> object's bitmap data is modified according to *options*. For example, if the [premultiplyAlpha](#)<sup>p1185</sup> option is set to ["premultiply"](#)<sup>p1185</sup>, the [bitmap.data](#)<sup>p1182</sup>'s color channels are [premultiplied by its alpha channel](#)<sup>p748</sup>.

Rejects the promise with an ["InvalidStateError"](#) DOMException if the source image is not in a valid state (e.g., an [img](#)<sup>p346</sup> element that hasn't loaded successfully, an [ImageBitmap](#)<sup>p1181</sup> object whose [\[\[Detached\]\]](#)<sup>p118</sup> internal slot value is true, an [ImageData](#)<sup>p686</sup> object whose [data](#)<sup>p727</sup> attribute value's [\[\[ViewedArrayBuffer\]\]](#) internal slot is detached, or a [Blob](#) whose data cannot be interpreted as a bitmap image).

Rejects the promise with a ["SecurityError"](#) DOMException if the script is not allowed to access the image data of the source image (e.g. a [video](#)<sup>p406</sup> that is [CORS-cross-origin](#)<sup>p98</sup>, or a [canvas](#)<sup>p677</sup> being drawn on by a script in a worker from another

[origin](#)<sup>p898</sup>).

**[imageBitmap.close](#)**<sup>p1185</sup>()

Releases *imageBitmap*'s underlying [bitmap data](#)<sup>p1182</sup>.

**[imageBitmap.width](#)**<sup>p1185</sup>

Returns the [natural width](#) of the image, in [CSS pixels](#).

**[imageBitmap.height](#)**<sup>p1185</sup>

Returns the [natural height](#) of the image, in [CSS pixels](#).

An [ImageBitmap](#)<sup>p1181</sup> object whose [\[\[Detached\]\]](#)<sup>p118</sup> internal slot value is false always has associated **bitmap data**, with a width and a height. However, it is possible for this data to be corrupted. If an [ImageBitmap](#)<sup>p1181</sup> object's media data can be decoded without errors, it is said to be **fully decodable**.

An [ImageBitmap](#)<sup>p1181</sup> object's bitmap has an [origin-clean](#)<sup>p678</sup> flag, which indicates whether the bitmap is tainted by content from a different [origin](#)<sup>p898</sup>. The flag is initially set to true and may be changed to false by the steps of [createImageBitmap\(\)](#)<sup>p1182</sup>.

[ImageBitmap](#)<sup>p1181</sup> objects are [serializable objects](#)<sup>p117</sup> and [transferable objects](#)<sup>p118</sup>.

Their [serialization steps](#)<sup>p117</sup>, given *value* and *serialized*, are:

1. If *value*'s [origin-clean](#)<sup>p678</sup> flag is not set, then throw a ["DataCloneError"](#) DOMException.
2. Set *serialized*.[[BitmapData]] to a copy of *value*'s [bitmap data](#)<sup>p1182</sup>.

Their [deserialization steps](#)<sup>p117</sup>, given *serialized*, *value*, and *targetRealm*, are:

1. Set *value*'s [bitmap data](#)<sup>p1182</sup> to *serialized*.[[BitmapData]].

Their [transfer steps](#)<sup>p118</sup>, given *value* and *dataHolder*, are:

1. If *value*'s [origin-clean](#)<sup>p678</sup> flag is not set, then throw a ["DataCloneError"](#) DOMException.
2. Set *dataHolder*.[[BitmapData]] to *value*'s [bitmap data](#)<sup>p1182</sup>.
3. Unset *value*'s [bitmap data](#)<sup>p1182</sup>.

Their [transfer-receiving steps](#)<sup>p118</sup>, given *dataHolder* and *value*, are:

1. Set *value*'s [bitmap data](#)<sup>p1182</sup> to *dataHolder*.[[BitmapData]].

The [createImageBitmap\(image, options\)](#) and [createImageBitmap\(image sx, sy, sw, sh, options\)](#) methods, when invoked, must run these steps:

1. If either *sw* or *sh* is given and is 0, then return [a promise rejected with](#) a [RangeError](#).
2. If either *options*'s [resizeWidth](#) or *options*'s [resizeHeight](#) is present and is 0, then return [a promise rejected with](#) an ["InvalidStateError"](#) DOMException.
3. [Check the usability of the image argument](#)<sup>p711</sup>. If this throws an exception or returns *bad*, then return [a promise rejected with](#) an ["InvalidStateError"](#) DOMException.
4. Let *p* be a new promise.
5. Let *imageBitmap* be a new [ImageBitmap](#)<sup>p1181</sup> object.
6. Switch on *image*:
  - ↪ [img](#)<sup>p346</sup>
  - ↪ [SVG image](#)
  - 1. If *image*'s media data has no [natural dimensions](#) (e.g., it's a vector graphic with no specified content size) and either *options*'s [resizeWidth](#)<sup>p1182</sup> or *options*'s [resizeHeight](#)<sup>p1182</sup> is not present, then return [a promise](#)

rejected with an `"InvalidStateError"` `DOMException`.

2. If *image*'s media data has no [natural dimensions](#) (e.g., it's a vector graphic with no specified content size), it should be rendered to a bitmap of the size specified by the [resizeWidth](#)<sup>p1182</sup> and the [resizeHeight](#)<sup>p1182</sup> options.
3. Set *imageBitmap*'s [bitmap data](#)<sup>p1182</sup> to a copy of *image*'s media data, [cropped to the source rectangle with formatting](#)<sup>p1184</sup>. If this is an animated image, *imageBitmap*'s [bitmap data](#)<sup>p1182</sup> must only be taken from the default image of the animation (the one that the format defines is to be used when animation is not supported or is disabled), or, if there is no such image, the first frame of the animation.
4. If *image* is [not origin-clean](#)<sup>p712</sup>, then set the [origin-clean](#)<sup>p678</sup> flag of *imageBitmap*'s bitmap to false.
5. Run this step [in parallel](#)<sup>p43</sup>:
  1. Resolve *p* with *imageBitmap*.

#### ↪ [video](#)<sup>p486</sup>

1. If *image*'s [networkState](#)<sup>p418</sup> attribute is `NETWORK_EMPTY`<sup>p418</sup>, then return [a promise rejected with](#) an `"InvalidStateError"` `DOMException`.
2. Set *imageBitmap*'s [bitmap data](#)<sup>p1182</sup> to a copy of the frame at the [current playback position](#)<sup>p432</sup>, at the [media resource](#)<sup>p415</sup>'s [natural width](#)<sup>p409</sup> and [natural height](#)<sup>p409</sup> (i.e., after any aspect-ratio correction has been applied), [cropped to the source rectangle with formatting](#)<sup>p1184</sup>.
3. If *image* is [not origin-clean](#)<sup>p712</sup>, then set the [origin-clean](#)<sup>p678</sup> flag of *imageBitmap*'s bitmap to false.
4. Run this step [in parallel](#)<sup>p43</sup>:
  1. Resolve *p* with *imageBitmap*.

#### ↪ [canvas](#)<sup>p677</sup>

1. Set *imageBitmap*'s [bitmap data](#)<sup>p1182</sup> to a copy of *image*'s [bitmap data](#)<sup>p1182</sup>, [cropped to the source rectangle with formatting](#)<sup>p1184</sup>.
2. Set the [origin-clean](#)<sup>p678</sup> flag of the *imageBitmap*'s bitmap to the same value as the [origin-clean](#)<sup>p678</sup> flag of *image*'s bitmap.
3. Run this step [in parallel](#)<sup>p43</sup>:
  1. Resolve *p* with *imageBitmap*.

#### ↪ [Blob](#)

Run these steps [in parallel](#)<sup>p43</sup>:

1. Let *imageData* be the result of reading *image*'s data. If an [error occurs during reading of the object](#)<sup>p61</sup>, then reject *p* with an `"InvalidStateError"` `DOMException` and abort these steps.
2. Apply the [image sniffing rules](#) to determine the file format of *imageData*, with MIME type of *image* (as given by *image*'s [type](#) attribute) giving the official type.
3. If *imageData* is not in a supported image file format (e.g., it's not an image at all), or if *imageData* is corrupted in some fatal way such that the image dimensions cannot be obtained (e.g., a vector graphic with no natural size), then reject *p* with an `"InvalidStateError"` `DOMException` and abort these steps.
4. Set *imageBitmap*'s [bitmap data](#)<sup>p1182</sup> to *imageData*, [cropped to the source rectangle with formatting](#)<sup>p1184</sup>. If this is an animated image, *imageBitmap*'s [bitmap data](#)<sup>p1182</sup> must only be taken from the default image of the animation (the one that the format defines is to be used when animation is not supported or is disabled), or, if there is no such image, the first frame of the animation.
5. Resolve *p* with *imageBitmap*.

#### ↪ [ImageData](#)<sup>p686</sup>

1. Let *buffer* be *image*'s [data](#)<sup>p727</sup> attribute value's `[[ViewedArrayBuffer]]` internal slot.
2. If `IsDetachedBuffer(buffer)` is true, then return [a promise rejected with](#) an `"InvalidStateError"` `DOMException`.

3. Set *imageBitmap*'s [bitmap\\_data<sup>p1182</sup>](#) to *image*'s image data, [cropped to the source rectangle with formatting<sup>p1184</sup>](#).
4. Run this step [in parallel<sup>p43</sup>](#):
  1. Resolve *p* with *imageBitmap*.

↪ **ImageBitmap<sup>p1181</sup>**

1. Set *imageBitmap*'s [bitmap\\_data<sup>p1182</sup>](#) to a copy of *image*'s [bitmap\\_data<sup>p1182</sup>](#), [cropped to the source rectangle with formatting<sup>p1184</sup>](#).
2. Set the [origin-clean<sup>p678</sup>](#) flag of *imageBitmap*'s bitmap to the same value as the [origin-clean<sup>p678</sup>](#) flag of *image*'s bitmap.
3. Run this step [in parallel<sup>p43</sup>](#):
  1. Resolve *p* with *imageBitmap*.

↪ **VideoFrame**

1. Set *imageBitmap*'s [bitmap\\_data<sup>p1182</sup>](#) to a copy of *image*'s visible pixel data, [cropped to the source rectangle with formatting<sup>p1184</sup>](#).
2. Run this step [in parallel<sup>p43</sup>](#):
  1. Resolve *p* with *imageBitmap*.

7. Return *p*.

When the steps above require that the user agent **crop bitmap data to the source rectangle with formatting**, the user agent must run the following steps:

1. Let *input* be the [bitmap\\_data<sup>p1182</sup>](#) being transformed.
2. If *sx*, *sy*, *sw* and *sh* are specified, let *sourceRectangle* be a rectangle whose corners are the four points (*sx*, *sy*), (*sx*+*sw*, *sy*), (*sx*+*sw*, *sy*+*sh*), (*sx*, *sy*+*sh*). Otherwise, let *sourceRectangle* be a rectangle whose corners are the four points (0, 0), (width of *input*, 0), (width of *input*, height of *input*), (0, height of *input*).

**Note**

*If either *sw* or *sh* are negative, then the top-left corner of this rectangle will be to the left or above the (*sx*, *sy*) point.*

3. Let *outputWidth* be determined as follows:
  - ↪ If the [resizeWidth<sup>p1182</sup>](#) member of *options* is specified  
the value of the [resizeWidth<sup>p1182</sup>](#) member of *options*
  - ↪ If the [resizeWidth<sup>p1182</sup>](#) member of *options* is not specified, but the [resizeHeight<sup>p1182</sup>](#) member is specified  
the width of *sourceRectangle*, times the value of the [resizeHeight<sup>p1182</sup>](#) member of *options*, divided by the height of *sourceRectangle*, rounded up to the nearest integer
  - ↪ If neither [resizeWidth<sup>p1182</sup>](#) nor [resizeHeight<sup>p1182</sup>](#) are specified  
the width of *sourceRectangle*
4. Let *outputHeight* be determined as follows:
  - ↪ If the [resizeHeight<sup>p1182</sup>](#) member of *options* is specified  
the value of the [resizeHeight<sup>p1182</sup>](#) member of *options*
  - ↪ If the [resizeHeight<sup>p1182</sup>](#) member of *options* is not specified, but the [resizeWidth<sup>p1182</sup>](#) member is specified  
the height of *sourceRectangle*, times the value of the [resizeWidth<sup>p1182</sup>](#) member of *options*, divided by the width of *sourceRectangle*, rounded up to the nearest integer
  - ↪ If neither [resizeWidth<sup>p1182</sup>](#) nor [resizeHeight<sup>p1182</sup>](#) are specified  
the height of *sourceRectangle*
5. Place *input* on an infinite [transparent black](#) grid plane, positioned so that its top left corner is at the origin of the plane, with the x-coordinate increasing to the right, and the y-coordinate increasing down, and with each pixel in the *input* image data occupying a cell on the plane's grid.

6. Let *output* be the rectangle on the plane denoted by *sourceRectangle*.
7. Scale *output* to the size specified by *outputWidth* and *outputHeight*. The user agent should use the value of the **resizeQuality** option to guide the choice of scaling algorithm.
8. If the value of the **imageOrientation** member of *options* is "**flipY**", *output* must be flipped vertically, disregarding any image orientation metadata of the source (such as EXIF metadata), if any. [EXIF]<sup>p1478</sup>

**Note**

*If the value is "**from-image**", no extra step is needed.*

**Note**

*There used to be a "**none**" enum value. It was renamed to "**from-image**"<sup>p1185</sup>. In the future, "**none**"<sup>p1185</sup> will be added back with a different meaning.*

9. If *image* is an **img**<sup>p346</sup> element or a **Blob** object, let *val* be the value of the **colorSpaceConversion** member of *options*, and then run these substeps:
  1. If *val* is "**default**", the color space conversion behavior is implementation-specific, and should be chosen according to the default color space that the implementation uses for drawing images onto the canvas.
  2. If *val* is "**none**", *output* must be decoded without performing any color space conversions. This means that the image decoding algorithm must ignore color profile metadata embedded in the source data as well as the display device color profile.
10. Let *val* be the value of **premultiplyAlpha** member of *options*, and then run these substeps:
  1. If *val* is "**default**", the alpha premultiplication behavior is implementation-specific, and should be chosen according to implementation deems optimal for drawing images onto the canvas.
  2. If *val* is "**premultiply**", the *output* that is not premultiplied by alpha must have its color components **multiplied by alpha**<sup>p749</sup> and that is premultiplied by alpha must be left untouched.
  3. If *val* is "**none**", the *output* that is not premultiplied by alpha must be left untouched and that is premultiplied by alpha must have its color components **divided by alpha**<sup>p749</sup>.
11. Return *output*.

The **close()** method steps are:

1. Set *this*'s **[[Detached]]**<sup>p118</sup> internal slot value to true.
2. Unset *this*'s **bitmap data**<sup>p1182</sup>.

The **width** getter steps are:

1. If *this*'s **[[Detached]]**<sup>p118</sup> internal slot's value is true, then return 0.
2. Return *this*'s width, in **CSS pixels**.

The **height** getter steps are:

1. If *this*'s **[[Detached]]**<sup>p118</sup> internal slot's value is true, then return 0.
2. Return *this*'s height, in **CSS pixels**.

The **ResizeQuality**<sup>p1181</sup> enumeration is used to express a preference for the interpolation quality to use when scaling images.

The "**pixelated**" value indicates a preference for scaling the image to preserve the pixelation of the original as much as possible, with minor smoothing as necessary to avoid distorting the image when the target size is not a clean multiple of the original.

To implement "**pixelated**"<sup>p1185</sup>, for each axis independently, first determine the integer multiple of its natural size that puts it closest to the target size and is greater than zero. Scale it to this integer-multiple-size using nearest neighbor, then scale it the rest of the way to the target size using bilinear interpolation.

The "**low**" value indicates a preference for a low level of image interpolation quality. Low-quality image interpolation may be more computationally efficient than higher settings.

The **"medium"** value indicates a preference for a medium level of image interpolation quality.

The **"high"** value indicates a preference for a high level of image interpolation quality. High-quality image interpolation may be more computationally expensive than lower settings.

#### Note

*Bilinear scaling is an example of a relatively fast, lower-quality image-smoothing algorithm. Bicubic or Lanczos scaling are examples of image-scaling algorithms that produce higher-quality output. This specification does not mandate that specific interpolation algorithms be used, except for **"pixelated"** as described above.*

#### Example

Using this API, a sprite sheet can be precut and prepared:

```
var sprites = {};  
function loadMySprites() {  
  var image = new Image();  
  image.src = 'mysprites.png';  
  var resolver;  
  var promise = new Promise(function (arg) { resolver = arg });  
  image.onload = function () {  
    resolver(Promise.all([  
      createImageBitmap(image, 0, 0, 40, 40).then(function (image) { sprites.person = image }),  
      createImageBitmap(image, 40, 0, 40, 40).then(function (image) { sprites.grass = image }),  
      createImageBitmap(image, 80, 0, 40, 40).then(function (image) { sprites.tree = image }),  
      createImageBitmap(image, 0, 40, 40, 40).then(function (image) { sprites.hut = image }),  
      createImageBitmap(image, 40, 40, 40, 40).then(function (image) { sprites.apple = image }),  
      createImageBitmap(image, 80, 40, 40, 40).then(function (image) { sprites.snake = image })  
    ]));  
  };  
  return promise;  
}  
  
function runDemo() {  
  var canvas = document.querySelector('canvas#demo');  
  var context = canvas.getContext('2d');  
  context.drawImage(sprites.tree, 30, 10);  
  context.drawImage(sprites.snake, 70, 10);  
}  
  
loadMySprites().then(runDemo);
```

## 8.11 Animation frames <sup>§P11</sup><sub>86</sub>

Some objects include the **AnimationFrameProvider**<sup>P1186</sup> interface mixin.

```
IDL callback FrameRequestCallback = undefined (DOMHighResTimeStamp time);  
  
interface mixin AnimationFrameProvider {  
  unsigned long requestAnimationFrame(FrameRequestCallback callback);  
  undefined cancelAnimationFrame(unsigned long handle);  
};  
Window includes AnimationFrameProvider;  
DedicatedWorkerGlobalScope includes AnimationFrameProvider;
```

Each **AnimationFrameProvider**<sup>P1186</sup> object also has a **target object** that stores the provider's internal state. It is defined as follows:

If the [AnimationFrameProvider](#)<sup>p1186</sup> is a [Window](#)<sup>p922</sup>

The [Window](#)<sup>p922</sup>'s [associated Document](#)<sup>p923</sup>

If the [AnimationFrameProvider](#)<sup>p1186</sup> is a [DedicatedWorkerGlobalScope](#)<sup>p1230</sup>

The [DedicatedWorkerGlobalScope](#)<sup>p1230</sup>

Each [target object](#)<sup>p1186</sup> has a **map of animation frame callbacks**, which is an [ordered map](#) that must be initially empty, and an **animation frame callback identifier**, which is a number that must initially be zero.

An [AnimationFrameProvider](#)<sup>p1186</sup> *provider* is considered **supported** if any of the following are true:

- *provider* is a [Window](#)<sup>p922</sup>.
- *provider*'s [owner set](#)<sup>p1228</sup> contains a [Document](#)<sup>p130</sup> object.
- Any of the [DedicatedWorkerGlobalScope](#)<sup>p1230</sup> objects in *provider*'s [owner set](#)<sup>p1228</sup> are [supported](#)<sup>p1187</sup>.

The **[requestAnimationFrame\(callback\)](#)** method steps are:

1. If *this* is not [supported](#)<sup>p1187</sup>, then throw a **"NotSupportedError"** [DOMException](#).
2. Let *target* be *this*'s [target object](#)<sup>p1186</sup>.
3. Increment *target*'s [animation frame callback identifier](#)<sup>p1187</sup> by one, and let *handle* be the result.
4. Let *callbacks* be *target*'s [map of animation frame callbacks](#)<sup>p1187</sup>.
5. **Set** *callbacks*[*handle*] to *callback*.
6. Return *handle*.

The **[cancelAnimationFrame\(handle\)](#)** method steps are:

1. If *this* is not [supported](#)<sup>p1187</sup>, then throw a **"NotSupportedError"** [DOMException](#).
2. Let *callbacks* be *this*'s [target object](#)<sup>p1186</sup>'s [map of animation frame callbacks](#)<sup>p1187</sup>.
3. **Remove** *callbacks*[*handle*].

To **run the animation frame callbacks** for a [target object](#)<sup>p1186</sup> *target* with a timestamp *now*:

1. Let *callbacks* be *target*'s [map of animation frame callbacks](#)<sup>p1187</sup>.
2. Let *callbackHandles* be the result of [getting the keys](#) of *callbacks*.
3. **For each** *handle* in *callbackHandles*, if *handle* [exists](#) in *callbacks*:
  1. Let *callback* be *callbacks*[*handle*].
  2. **Remove** *callbacks*[*handle*].
  3. **Invoke** *callback* with « *now* » and "report".

#### Example

Inside workers, [requestAnimationFrame\(\)](#)<sup>p1187</sup> can be used together with an [OffscreenCanvas](#)<sup>p741</sup> transferred from a [canvas](#)<sup>p677</sup> element. First, in the document, transfer control to the worker:

```
const offscreenCanvas = document.getElementById("c").transferControlToOffscreen();
worker.postMessage(offscreenCanvas, [offscreenCanvas]);
```

Then, in the worker, the following code will draw a rectangle moving from left to right:

```
let ctx, pos = 0;
function draw(dt) {
  ctx.clearRect(0, 0, 100, 100);
```

```
ctx.fillRect(pos, 0, 10, 10);  
pos += 10 * dt;  
requestAnimationFrame(draw);  
}  
  
self.onmessage = function(ev) {  
  const transferredCanvas = ev.data;  
  ctx = transferredCanvas.getContext("2d");  
  draw();  
};
```

## 9 Communication §<sup>p11</sup> 89

### Note

The `WebSocket` interface used to be defined here. It is now defined in `WebSockets`. [\[WEBSOCKETS\]](#)<sup>p1484</sup>

### 9.1 The `MessageEvent`<sup>p1189</sup> interface §<sup>p11</sup> 89

✓ MDN

Messages in [server-sent events](#)<sup>p1190</sup>, [cross-document messaging](#)<sup>p1199</sup>, [channel messaging](#)<sup>p1202</sup>, [broadcast channels](#)<sup>p1209</sup>, and `WebSockets` use the `MessageEvent`<sup>p1189</sup> interface for their `message`<sup>p1471</sup> events: [\[WEBSOCKETS\]](#)<sup>p1484</sup>

```
IDL [Exposed=(Window,Worker,AudioWorklet)]
interface MessageEvent : Event {
  constructor(DOMString type, optional MessageEventInit eventInitDict = {});

  readonly attribute any data;
  readonly attribute USVString origin;
  readonly attribute DOMString lastEventId;
  readonly attribute MessageEventSource? source;
  readonly attribute FrozenArray<MessagePort> ports;

  undefined initMessageEvent(DOMString type, optional boolean bubbles = false, optional boolean
cancelable = false, optional any data = null, optional USVString origin = "", optional DOMString
lastEventId = "", optional MessageEventSource? source = null, optional sequence<MessagePort> ports =
[]);
};

dictionary MessageEventInit : EventInit {
  any data = null;
  USVString origin = "";
  DOMString lastEventId = "";
  MessageEventSource? source = null;
  sequence<MessagePort> ports = [];
};

typedef (WindowProxy or MessagePort or ServiceWorker) MessageEventSource;
```

For web developers (non-normative)

#### `event.data`<sup>p1189</sup>

Returns the data of the message.

#### `event.origin`<sup>p1190</sup>

Returns the origin of the message, for [server-sent events](#)<sup>p1190</sup> and [cross-document messaging](#)<sup>p1199</sup>.

#### `event.lastEventId`<sup>p1190</sup>

Returns the [last event ID string](#)<sup>p1191</sup>, for [server-sent events](#)<sup>p1190</sup>.

#### `event.source`<sup>p1190</sup>

Returns the [WindowProxy](#)<sup>p934</sup> of the source window, for [cross-document messaging](#)<sup>p1199</sup>, and the [MessagePort](#)<sup>p1205</sup> being attached, in the [connect](#)<sup>p1471</sup> event fired at [SharedWorkerGlobalScope](#)<sup>p1230</sup> objects.

#### `event.ports`<sup>p1190</sup>

Returns the [MessagePort](#)<sup>p1205</sup> array sent with the message, for [cross-document messaging](#)<sup>p1199</sup> and [channel messaging](#)<sup>p1202</sup>.

The `data` attribute must return the value it was initialized to. It represents the message being sent.

The **origin** attribute must return the value it was initialized to. It represents, in [server-sent events](#)<sup>p1190</sup> and [cross-document messaging](#)<sup>p1199</sup>, the [origin](#) of the document that sent the message (typically the scheme, hostname, and port of the document, but not its path or [fragment](#)).

The **lastEventId** attribute must return the value it was initialized to. It represents, in [server-sent events](#)<sup>p1190</sup>, the [last event ID string](#)<sup>p1191</sup> of the event source.

The **source** attribute must return the value it was initialized to. It represents, in [cross-document messaging](#)<sup>p1199</sup>, the [WindowProxy](#)<sup>p934</sup> of the [browsing context](#)<sup>p998</sup> of the [Window](#)<sup>p922</sup> object from which the message came; and in the [connect](#)<sup>p1471</sup> events used by [shared workers](#)<sup>p1230</sup>, the newly connecting [MessagePort](#)<sup>p1205</sup>.

The **ports** attribute must return the value it was initialized to. It represents, in [cross-document messaging](#)<sup>p1199</sup> and [channel messaging](#)<sup>p1202</sup>, the [MessagePort](#)<sup>p1205</sup> array being sent.

The **initMessageEvent(*type, bubbles, cancelable, data, origin, lastEventId, source, ports*)** method must initialize the event in a manner analogous to the similarly-named **initEvent()** method. [\[DOM\]](#)<sup>p1478</sup>

#### Note

Various APIs (e.g., [WebSocket](#), [EventSource](#)<sup>p1191</sup>) use the [MessageEvent](#)<sup>p1189</sup> interface for their [message](#)<sup>p1471</sup> event without using the [MessagePort](#)<sup>p1205</sup> API.

## 9.2 Server-sent events <sup>p1190</sup>

### 9.2.1 Introduction <sup>p1190</sup>

*This section is non-normative.*

To enable servers to push data to web pages over HTTP or using dedicated server-push protocols, this specification introduces the [EventSource](#)<sup>p1191</sup> interface.

Using this API consists of creating an [EventSource](#)<sup>p1191</sup> object and registering an event listener.

```
var source = new EventSource('updates.cgi');
source.onmessage = function (event) {
  alert(event.data);
};
```

On the server-side, the script ("updates.cgi" in this case) sends messages in the following form, with the [text/event-stream](#)<sup>p1449</sup> MIME type:

data: This is the first message.

data: This is the second message, it  
data: has two lines.

data: This is the third message.

Authors can separate events by using different event types. Here is a stream that has two event types, "add" and "remove":

event: add  
data: 73857293

event: remove  
data: 2153

event: add

data: 113411

The script to handle such a stream would look like this (where `addHandler` and `removeHandler` are functions that take one argument, the event):

```
var source = new EventSource('updates.cgi');
source.addEventListener('add', addHandler, false);
source.addEventListener('remove', removeHandler, false);
```

The default event type is "message".

Event streams are always decoded as UTF-8. There is no way to specify another character encoding.

Event stream requests can be redirected using HTTP 301 and 307 redirects as with normal HTTP requests. Clients will reconnect if the connection is closed; a client can be told to stop reconnecting using the HTTP 204 No Content response code.

Using this API rather than emulating it using [XMLHttpRequest](#) or an [iframe](#)<sup>p390</sup> allows the user agent to make better use of network resources in cases where the user agent implementer and the network operator are able to coordinate in advance. Amongst other benefits, this can result in significant savings in battery life on portable devices. This is discussed further in the section below on [connectionless push](#)<sup>p1197</sup>.

## 9.2.2 The [EventSource](#)<sup>p1191</sup> interface §<sup>p11</sup> 91

```
IDL [Exposed=(Window,Worker)]
interface EventSource : EventTarget {
  constructor(USVString url, optional EventSourceInit eventSourceInitDict = {});

  readonly attribute USVString url;
  readonly attribute boolean withCredentials;

  // ready state
  const unsigned short CONNECTING = 0;
  const unsigned short OPEN = 1;
  const unsigned short CLOSED = 2;
  readonly attribute unsigned short readyState;

  // networking
  attribute EventHandler onopen;
  attribute EventHandler onmessage;
  attribute EventHandler onerror;
  undefined close();
};

dictionary EventSourceInit {
  boolean withCredentials = false;
};
```

Each [EventSource](#)<sup>p1191</sup> object has the following associated with it:

- A **url** (a [URL record](#)). Set during construction.
- A **request**. This must initially be null.
- A **reconnection time**, in milliseconds. This must initially be an [implementation-defined](#) value, probably in the region of a few seconds.
- A **last event ID string**. This must initially be the empty string.

Apart from [url](#)<sup>p1191</sup> these are not currently exposed on the [EventSource](#)<sup>p1191</sup> object.

**source** = new **EventSource**<sup>p1192</sup>( *url* [, { **withCredentials**<sup>p1191</sup>: true } ] )

Creates a new **EventSource**<sup>p1191</sup> object.

*url* is a string giving the **URL** that will provide the event stream.

Setting **withCredentials**<sup>p1191</sup> to true will set the **credentials mode** for connection requests to *url* to "include".

**source.close**<sup>p1193</sup>()

Aborts any instances of the **fetch** algorithm started for this **EventSource**<sup>p1191</sup> object, and sets the **readyState**<sup>p1193</sup> attribute to **CLOSED**<sup>p1193</sup>.

**source.url**<sup>p1193</sup>

Returns the **URL providing the event stream**<sup>p1191</sup>.

**source.withCredentials**<sup>p1193</sup>

Returns true if the **credentials mode** for connection requests to the **URL providing the event stream**<sup>p1191</sup> is set to "include", and false otherwise.

**source.readyState**<sup>p1193</sup>

Returns the state of this **EventSource**<sup>p1191</sup> object's connection. It can have the values described below.

The **EventSource**(*url*, *eventSourceInitDict*) constructor, when invoked, must run these steps:

1. Let *ev* be a new **EventSource**<sup>p1191</sup> object.
2. Let *settings* be *ev*'s **relevant settings object**<sup>p1083</sup>.
3. Let *urlRecord* be the result of **encoding-parsing a URL**<sup>p97</sup> given *url*, relative to *settings*.
4. If *urlRecord* is failure, then throw a **"SyntaxError" DOMException**.
5. Set *ev*'s **url**<sup>p1191</sup> to *urlRecord*.
6. Let *corsAttributeState* be **Anonymous**<sup>p99</sup>.
7. If the value of *eventSourceInitDict*'s **withCredentials**<sup>p1191</sup> member is true, then set *corsAttributeState* to **Use Credentials**<sup>p99</sup> and set *ev*'s **withCredentials**<sup>p1193</sup> attribute to true.
8. Let *request* be the result of **creating a potential-CORS request**<sup>p98</sup> given *urlRecord*, the empty string, and *corsAttributeState*.
9. Set *request*'s **client** to *settings*.
10. User agents may **set** (**`Accept`**, **`text/event-stream`**<sup>p1449</sup>) in *request*'s **header list**.
11. Set *request*'s **cache mode** to "no-store".
12. Set *request*'s **initiator type** to "other".
13. Set *ev*'s **request**<sup>p1191</sup> to *request*.
14. Let *processEventSourceEndOfBody* given **response** *res* be the following step: if *res* is not a **network error**, then **reestablish the connection**<sup>p1193</sup>.
15. **Fetch** *request*, with **processResponseEndOfBody** set to *processEventSourceEndOfBody* and **processResponse** set to the following steps given **response** *res*:
  1. If *res* is an **aborted network error**, then **fail the connection**<sup>p1194</sup>.
  2. Otherwise, if *res* is a **network error**, then **reestablish the connection**<sup>p1193</sup>, unless the user agent knows that to be futile, in which case the user agent may **fail the connection**<sup>p1194</sup>.
  3. Otherwise, if *res*'s **status** is not 200, or if *res*'s **Content-Type**<sup>p98</sup> is not **`text/event-stream`**<sup>p1449</sup>, then **fail the connection**<sup>p1194</sup>.
  4. Otherwise, **announce the connection**<sup>p1193</sup> and **interpret**<sup>p1195</sup> *res*'s **body** line by line.
16. Return *ev*.

The `url` attribute's getter must return the [serialization](#) of this [EventSource<sup>p1191</sup>](#) object's [url<sup>p1191</sup>](#).

The `withCredentials` attribute must return the value to which it was last initialized. When the object is created, it must be initialized to false.

The `readyState` attribute represents the state of the connection. It can have the following values:

**CONNECTING (numeric value 0)**

The connection has not yet been established, or it was closed and the user agent is reconnecting.

**OPEN (numeric value 1)**

The user agent has an open connection and is dispatching events as it receives them.

**CLOSED (numeric value 2)**

The connection is not open, and the user agent is not trying to reconnect. Either there was a fatal error or the [close\(\)<sup>p1193</sup>](#) method was invoked.

When the object is created its [readyState<sup>p1193</sup>](#) must be set to [CONNECTING<sup>p1193</sup>](#) (0). The rules given below for handling the connection define when the value changes.

The [close\(\)<sup>p1193</sup>](#) method must abort any instances of the [fetch](#) algorithm started for this [EventSource<sup>p1191</sup>](#) object, and must set the [readyState<sup>p1193</sup>](#) attribute to [CLOSED<sup>p1193</sup>](#).

The following are the [event handlers<sup>p1136</sup>](#) (and their corresponding [event handler event types<sup>p1139</sup>](#)) that must be supported, as [event handler IDL attributes<sup>p1137</sup>](#), by all objects implementing the [EventSource<sup>p1191</sup>](#) interface:

<a href="#">Event handler<sup>p1136</sup></a>	<a href="#">Event handler event type<sup>p1139</sup></a>
<a href="#">onopen</a>	<a href="#">open<sup>p1472</sup></a>
<a href="#">onmessage</a>	<a href="#">message<sup>p1471</sup></a>
<a href="#">onerror</a>	<a href="#">error<sup>p1471</sup></a>

9.2.3 Processing model <sup>§ p1193</sup>

When a user agent is to **announce the connection**, the user agent must [queue a task<sup>p1125</sup>](#) which, if the [readyState<sup>p1193</sup>](#) attribute is set to a value other than [CLOSED<sup>p1193</sup>](#), sets the [readyState<sup>p1193</sup>](#) attribute to [OPEN<sup>p1193</sup>](#) and [fires an event](#) named [open<sup>p1472</sup>](#) at the [EventSource<sup>p1191</sup>](#) object.

When a user agent is to **reestablish the connection**, the user agent must run the following steps. These steps are run [in parallel<sup>p43</sup>](#), not as part of a [task<sup>p1124</sup>](#). (The tasks that it queues, of course, are run like normal tasks and not themselves [in parallel<sup>p43</sup>](#).)

1. [Queue a task<sup>p1125</sup>](#) to run the following steps:
  1. If the [readyState<sup>p1193</sup>](#) attribute is set to [CLOSED<sup>p1193</sup>](#), abort the task.
  2. Set the [readyState<sup>p1193</sup>](#) attribute to [CONNECTING<sup>p1193</sup>](#).
  3. [Fire an event](#) named [error<sup>p1471</sup>](#) at the [EventSource<sup>p1191</sup>](#) object.
2. Wait a delay equal to the reconnection time of the event source.
3. Optionally, wait some more. In particular, if the previous attempt failed, then user agents might introduce an exponential backoff delay to avoid overloading a potentially already overloaded server. Alternatively, if the operating system has reported that there is no network connectivity, user agents might wait for the operating system to announce that the network connection has returned before retrying.
4. Wait until the aforementioned task has run, if it has not yet run.
5. [Queue a task<sup>p1125</sup>](#) to run the following steps:
  1. If the [EventSource<sup>p1191</sup>](#) object's [readyState<sup>p1193</sup>](#) attribute is not set to [CONNECTING<sup>p1193</sup>](#), then return.
  2. Let *request* be the [EventSource<sup>p1191</sup>](#) object's [request<sup>p1191</sup>](#).
  3. If the [EventSource<sup>p1191</sup>](#) object's [last event ID string<sup>p1191</sup>](#) is not the empty string, then:

1. Let *lastEventIDValue* be the [EventSource](#)<sup>p1191</sup> object's [last event ID string](#)<sup>p1191</sup>, [encoded as UTF-8](#).
2. [Set](#) (``Last-Event-ID`p1194`, *lastEventIDValue*) in *request*'s [header list](#).
4. [Fetch request](#) and process the response obtained in this fashion, if any, as described earlier in this section.

When a user agent is to **fail the connection**, the user agent must [queue a task](#)<sup>p1125</sup> which, if the [readyState](#)<sup>p1193</sup> attribute is set to a value other than [CLOSED](#)<sup>p1193</sup>, sets the [readyState](#)<sup>p1193</sup> attribute to [CLOSED](#)<sup>p1193</sup> and [fires an event](#) named [error](#)<sup>p1471</sup> at the [EventSource](#)<sup>p1191</sup> object. **Once the user agent has [failed the connection](#)<sup>p1194</sup>, it does *not* attempt to reconnect.**

The [task source](#)<sup>p1124</sup> for any [tasks](#)<sup>p1124</sup> that are [queued](#)<sup>p1125</sup> by [EventSource](#)<sup>p1191</sup> objects is the **remote event task source**.

#### 9.2.4 The ``Last-Event-ID`p1194` header §<sup>p11</sup> 94

The `Last-Event-ID`` HTTP request header reports an [EventSource](#)<sup>p1191</sup> object's [last event ID string](#)<sup>p1191</sup> to the server when the user agent is to [reestablish the connection](#)<sup>p1193</sup>.

See [whatwg/html issue #7363](#) to define the value space better. It is essentially any UTF-8 encoded string, that does not contain U+0000 NULL, U+000A LF, or U+000D CR.

#### 9.2.5 Parsing an event stream §<sup>p11</sup> 94

This event stream format's [MIME type](#) is [text/event-stream](#)<sup>p1449</sup>.

The event stream format is as described by the `stream` production of the following ABNF, the character set for which is Unicode. [\[ABNF\]](#)<sup>p1475</sup>

```
stream      = [ bom ] *event
event       = *( comment / field ) end-of-line
comment     = colon *any-char end-of-line
field       = 1*name-char [ colon [ space ] *any-char ] end-of-line
end-of-line = ( cr lf / cr / lf )

; characters
lf          = %x000A ; U+000A LINE FEED (LF)
cr          = %x000D ; U+000D CARRIAGE RETURN (CR)
space       = %x0020 ; U+0020 SPACE
colon       = %x003A ; U+003A COLON (:)
bom         = %xFEFF ; U+FEFF BYTE ORDER MARK
name-char   = %x0000-0009 / %x000B-000C / %x000E-0039 / %x003B-10FFFF
              ; a scalar value other than U+000A LINE FEED (LF), U+000D CARRIAGE RETURN (CR), or
              U+003A COLON (:)
any-char    = %x0000-0009 / %x000B-000C / %x000E-10FFFF
              ; a scalar value other than U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR)
```

Event streams in this format must always be encoded as UTF-8. [\[ENCODING\]](#)<sup>p1478</sup>

Lines must be separated by either a U+000D CARRIAGE RETURN U+000A LINE FEED (CRLF) character pair, a single U+000A LINE FEED (LF) character, or a single U+000D CARRIAGE RETURN (CR) character.

Since connections established to remote servers for such resources are expected to be long-lived, UAs should ensure that appropriate buffering is used. In particular, while line buffering with lines are defined to end with a single U+000A LINE FEED (LF) character is safe, block buffering or line buffering with different expected line endings can cause delays in event dispatch.

## 9.2.6 Interpreting an event stream <sup>§p11</sup><sub>95</sub>

Streams must be decoded using the [UTF-8 decode](#) algorithm.

### Note

The [UTF-8 decode](#) algorithm strips one leading UTF-8 Byte Order Mark (BOM), if any.

The stream must then be parsed by reading everything line by line, with a U+000D CARRIAGE RETURN U+000A LINE FEED (CRLF) character pair, a single U+000A LINE FEED (LF) character not preceded by a U+000D CARRIAGE RETURN (CR) character, and a single U+000D CARRIAGE RETURN (CR) character not followed by a U+000A LINE FEED (LF) character being the ways in which a line can end.

When a stream is parsed, a *data* buffer, an *event type* buffer, and a *last event ID* buffer must be associated with it. They must be initialized to the empty string.

Lines must be processed, in the order they are received, as follows:

↪ **If the line is empty (a blank line)**

[Dispatch the event](#)<sup>p1195</sup>, as defined below.

↪ **If the line starts with a U+003A COLON character (:)**

Ignore the line.

↪ **If the line contains a U+003A COLON character (:)**

Collect the characters on the line before the first U+003A COLON character (:), and let *field* be that string.

Collect the characters on the line after the first U+003A COLON character (:), and let *value* be that string. If *value* starts with a U+0020 SPACE character, remove it from *value*.

[Process the field](#)<sup>p1195</sup> using the steps described below, using *field* as the field name and *value* as the field value.

↪ **Otherwise, the string is not empty but does not contain a U+003A COLON character (:)**

[Process the field](#)<sup>p1195</sup> using the steps described below, using the whole line as the field name, and the empty string as the field value.

Once the end of the file is reached, any pending data must be discarded. (If the file ends in the middle of an event, before the final empty line, the incomplete event is not dispatched.)

The steps to **process the field** given a field name and a field value depend on the field name, as given in the following list. Field names must be compared literally, with no case folding performed.

↪ **If the field name is "event"**

Set the *event type* buffer to field value.

↪ **If the field name is "data"**

Append the field value to the *data* buffer, then append a single U+000A LINE FEED (LF) character to the *data* buffer.

↪ **If the field name is "id"**

If the field value does not contain U+0000 NULL, then set the *last event ID* buffer to the field value. Otherwise, ignore the field.

↪ **If the field name is "retry"**

If the field value consists of only [ASCII digits](#), then interpret the field value as an integer in base ten, and set the event stream's [reconnection time](#)<sup>p1191</sup> to that integer. Otherwise, ignore the field.

↪ **Otherwise**

The field is ignored.

When the user agent is required to **dispatch the event**, the user agent must process the *data* buffer, the *event type* buffer, and the *last event ID* buffer using steps appropriate for the user agent.

For web browsers, the appropriate steps to [dispatch the event](#)<sup>p1195</sup> are as follows:

1. Set the [last event ID string](#)<sup>p1191</sup> of the event source to the value of the *last event ID* buffer. The buffer does not get reset, so

the [last event ID string](#)<sup>p1191</sup> of the event source remains set to this value until the next time it is set by the server.

2. If the *data* buffer is an empty string, set the *data* buffer and the *event type* buffer to the empty string and return.
3. If the *data* buffer's last character is a U+000A LINE FEED (LF) character, then remove the last character from the *data* buffer.
4. Let *event* be the result of [creating an event](#) using [MessageEvent](#)<sup>p1189</sup>, in the [relevant realm](#)<sup>p1083</sup> of the [EventSource](#)<sup>p1191</sup> object.
5. Initialize *event*'s *type* attribute to "[message](#)<sup>p1471</sup>", its *data*<sup>p1189</sup> attribute to *data*, its *origin*<sup>p1190</sup> attribute to the [serialization](#)<sup>p898</sup> of the *origin* of the event stream's final URL (i.e., the URL after redirects), and its *lastEventId*<sup>p1190</sup> attribute to the [last event ID string](#)<sup>p1191</sup> of the event source.
6. If the *event type* buffer has a value other than the empty string, change the *type* of the newly created event to equal the value of the *event type* buffer.
7. Set the *data* buffer and the *event type* buffer to the empty string.
8. [Queue a task](#)<sup>p1125</sup> which, if the *readyState*<sup>p1193</sup> attribute is set to a value other than [CLOSED](#)<sup>p1193</sup>, [dispatches](#) the newly created event at the [EventSource](#)<sup>p1191</sup> object.

#### Note

*If an event doesn't have an "id" field, but an earlier event did set the event source's [last event ID string](#)<sup>p1191</sup>, then the event's *lastEventId*<sup>p1190</sup> field will be set to the value of whatever the last seen "id" field was.*

For other user agents, the appropriate steps to [dispatch the event](#)<sup>p1195</sup> are implementation dependent, but at a minimum they must set the *data* and *event type* buffers to the empty string before returning.

#### Example

The following event stream, once followed by a blank line:

```
data: YH00
data: +2
data: 10
```

...would cause an event [message](#)<sup>p1471</sup> with the interface [MessageEvent](#)<sup>p1189</sup> to be dispatched on the [EventSource](#)<sup>p1191</sup> object. The event's *data*<sup>p1189</sup> attribute would contain the string "YH00\n+2\n10" (where "\n" represents a newline).

This could be used as follows:

```
var stocks = new EventSource("https://stocks.example.com/ticker.php");
stocks.onmessage = function (event) {
  var data = event.data.split('\n');
  updateStocks(data[0], data[1], data[2]);
};
```

...where `updateStocks()` is a function defined as:

```
function updateStocks(symbol, delta, value) { ... }
```

...or some such.

#### Example

The following stream contains four blocks. The first block has just a comment, and will fire nothing. The second block has two fields with names "data" and "id" respectively; an event will be fired for this block, with the data "first event", and will then set the last event ID to "1" so that if the connection died between this block and the next, the server would be sent a [Last-Event-ID](#)<sup>p1194</sup> header with the value `1`. The third block fires an event with data "second event", and also has an "id" field, this time with no value, which resets the last event ID to the empty string (meaning no [Last-Event-ID](#)<sup>p1194</sup> header will now be sent in the event of a reconnection being attempted). Finally, the last block just fires an event with the data " third event" (with a single leading space character). Note that the last still has to end with a blank line, the end of the stream is not enough to trigger the dispatch of the last event.

```
: test stream

data: first event
id: 1

data:second event
id

data:  third event
```

#### Example

The following stream fires two events:

```
data

data
data

data:
```

The first block fires events with the data set to the empty string, as would the last block if it was followed by a blank line. The middle block fires an event with the data set to a single newline character. The last block is discarded because it is not followed by a blank line.

#### Example

The following stream fires two identical events:

```
data:test

data: test
```

This is because the space after the colon is ignored if present.
